and distilling off the latter, a light yellow oil remains, boiling at  $200^{\circ}$ — $202^{\circ}$  C. 6.2 grms. of this oil, 2.2 grms. of benzaldehyde, and 5.7 grms. of hydrochloric acid were heated together as already described. Benzaldehyde distils over and the viscous melt is steamed to remove dimethyl-*p*-xylylene. The residue is filtered off and washed. An attempt to methylate *p*-xylylene by the ordinary method as below gave no satisfactory result. For the preparation of dimethylaniline the following quantities are employed. An autoclave is charged with 100 kilos. of aniline, 96.5 kilos. of methyl alcohol, 18—19 kilos. of sulphuric acid ( $64^{\circ}$  B.), and heated for 7 hours to  $200^{\circ}$ — $210^{\circ}$  C. After adding 40 kilos. of soda lye ( $40^{\circ}$  B.), the dimethylaniline is driven off with steam. The yield is 125 kilos., whilst 12—14 kilos. of methyl alcohol are recovered.

**Indazine.**—By condensing nitrosodimethylaniline with diphenyl-*m*-phenylene diamine, a valuable blue dyestuff is formed, and a homologue of this is obtained by oxidising dimethyl-*p*-phenylene diamine together with ditolyl-*m*-phenylene diamine. This latter substance is produced by heating together 1.1 kilo. of resorcinol, 1.3 kilos. of *p*-toluidine, and 1.4 kilo. of *p*-toluidine hydrochloride, in a cast-iron vessel, with an agitator, to  $170^{\circ}$ — $180^{\circ}$  C., when a mixture of water and *p*-toluidine distils over. The next day the temperature is raised to  $270^{\circ}$  C., and after about 30 hours' heating, the melt is boiled up in a 40 litre earthenware pot containing 1.5 kilo. of hydrochloric acid ( $20^{\circ}$  B.). The residue is then extracted with soda lye and the insoluble portion is recrystallised, from one and a half to twice its weight of benzene, forming slightly coloured needles. The yield is 2.6 kilos. For the preparation of the amidodimethylaniline, 37.3 grms. of nitrosodimethylaniline suspended in 750 grms. of alcohol (90 Tr.) were treated with 55 grms. of zinc dust. The reaction is completed by warming to  $40^{\circ}$ — $50^{\circ}$  C., and when the solution is decolorised, it is heated to boiling, and filtered from the zinc dust. 29 grms. of ditolyl-*m*-phenylene diamine are then dissolved in the filtrate, and to the clear, hot solution is added in small quantities, 300 c.c. of 50 per cent. alcohol, containing 60 grms. of sodium bichromate ( $\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$ ). The oxidation is completed by heating for 2 hours on the water-bath, when the alcohol is driven off with steam. The hot aqueous solution measuring about 2 litres, gives, on the addition of 240 c.c. of hydrochloric acid ( $11^{\circ}$  B.), a precipitate of the dyestuff, which, when dried, weighs 51 grms. It contains 4 per cent. of ash and is 30 per cent. stronger than ordinary indazine. The mother-liquor, on adding zinc chloride, yields a further 5—6 grms. of the dyestuff.

**Naphthohydroquinone.**—500 grms. of  $\beta$ -Naphthol Orange are dissolved in 2 litres of boiling water, to which 500 grms. of hydrochloric acid are added. At the same time 750 grms. of tin salt are dissolved in 725 grms. of hydrochloric acid, and added tolerably quickly to the first solution, with constant agitation. A mixture of sulphanilic acid and 1,2-amidonaphthol hydrochloride separates out, and, after filtering off, is dissolved in 8—10 litres of hot water. A small quantity of pure sulphanilic acid crystallises out, which is filtered off. The filtrate is precipitated with a concentrated sodium acetate solution, in the proportion of 300 grms. of the salt to 1 litre of the filtrate. After drying at air temperature, 150—170 grms. were obtained, corresponding to 70—72 per cent. of the theory. On evaporating the filtrate, about 80 grms. of sulphanilic acid are recovered. For oxidising the base, 160 grms. of it are stirred up with water to a thin paste, dissolved cold with 400 grms. of dilute sulphuric acid (1:1), and oxidised with 200 grms. of sodium bichromate in 300 c.c. of water. After 10 minutes the formation of the  $\beta$ -naphthoquinone is complete, giving 140—142 grms., corresponding to a yield of 90 per cent. of the theoretical. In order to reduce it, 140 grms. of the  $\beta$ -naphthoquinone as a 15 per cent. paste mixed with ice, are stirred into 8 litres of an aqueous solution of sulphurous acid. The temperature is maintained at  $8^{\circ}$ — $9^{\circ}$  C. by means of ice, and the  $\beta$ -naphthoquinone gradually dissolves. After standing 12 hours, naphthohydroquinone separates out, the filtrate being extracted with ether. The crude product so obtained was dissolved in 4 litres of water, together with 50 grms. of sulphurous acid, at about  $60^{\circ}$  C. The hydroquinone which separates out on cooling is again recrystallised

from 3 litres of water and 50 grms. of sulphurous acid. Any dimethylhydroquinone is removed by filtration, and the  $\beta$ -naphthohydroquinone separates out on cooling. The yield is 80 grms., being about 50 per cent. of the theoretical. It is, however, much cheaper to prepare 1,2-dihydroxynaphthalene from 1,2-nitronaphthol, which is easily obtained from  $\beta$ -naphthol by the following method:—20 kilos. of  $\beta$ -naphthol, 50 kilos. of denatured alcohol, 8 kilos. of zinc chloride in  $2\frac{1}{2}$  litres of water, and 5 kilos. of nitrite in 4—5 litres of water, are mixed in a stoneware three-necked Woulff's bottle which can be heated externally with steam. One tubulure is closed, another serves for the insertion of a thermometer, and the third is connected to an inverted condenser. The reaction commences at  $60^{\circ}$ — $70^{\circ}$  C., gradually rising to  $80^{\circ}$ — $85^{\circ}$  C., and is complete in about half an hour. The whole is then allowed to cool, the contents removed from the vessel by means of a vacuum, the zinc salt then filtered off, and twice washed each time with 10 kilos. of alcohol. After centrifuging, 22.5 kilos. of damp 1,2-nitronaphthol zinc salt are obtained. For the reduction to 1,2-amidonaphthol, it is necessary to first obtain the acid, and for this purpose the zinc salt obtained is stirred to a thick paste with water, cooled with ice to  $0^{\circ}$ — $3^{\circ}$  C., and decomposed with 20—25 kilos. of hydrochloric acid ( $20^{\circ}$  B.). The sludge so obtained is added to a solution of 30 kilos. of tin crystals (stannous chloride) in 60 kilos. of hydrochloric acid, keeping the temperature at about  $5^{\circ}$  C. The solution solidifies to a mass of greyish-white crystals, which, after filtering off, are dissolved in about 100 litres of water with the addition of about 10 kilos. of hydrochloric acid. Scrap zinc is then added so long as tin is precipitated, and the solution is filtered into an aqueous solution of sulphurous acid. After standing several days, 1,2-amidonaphthol hydrochloride separates out, or is precipitated by adding hydrochloric acid. The yield is 70—80 per cent. of the theoretical, calculated on the naphthol. The oxidation to  $\beta$ -naphthoquinone is effected by means of ferric chloride, the preparation of which from the iron sludge obtained in manufacturing aniline is described subsequently. 220 grms. of 1,2-amidonaphthol hydrochloride together with 100—110 grms. of sulphurous acid are dissolved in 2— $2\frac{1}{2}$  litres of boiling water. After filtering from a bulky greenish precipitate, the solution (which, with the washings, amounts to 5 litres) is, after cooling, mixed with 135 grms. of hydrochloric acid ( $20^{\circ}$  B.) and subsequently with a solution of 440 grms. of ferric chloride in 1 litre at a temperature of about  $10^{\circ}$  C. The light yellow crystalline precipitate of  $\beta$ -naphthoquinone is filtered off and washed with 2 litres of water, and after thoroughly draining weighed 270 grms. For the conversion into the hydroquinone, the precipitate is stirred up with water and added to 10—15 litres of water containing 1.5 litres of sulphurous acid. After standing some time the solution is extracted with 3 litres of ether, giving 82 grms. of the product, which corresponds to about 50 per cent. of the theoretical, assuming that 195 grms. of sodium 1,2-nitronaphtholate correspond to 220 grms. of amidonaphthol hydrochloride. By combining diazotised sulphanilic acid with naphthohydroquinone, an orange-yellow dyestuff is obtained which gives bluish-violet shades on chrome wool very fast to milling. Similar dyestuffs can be obtained from 2,1-naphthylamine sulphonic acid or from naphthionic acid, but since only low yields were obtained, their manufacture was not proceeded with.

For the preparation of the ferric chloride above alluded to, 33 kilos. of iron sludge from the manufacture of aniline were dissolved in 66 kilos. of hydrochloric acid ( $20^{\circ}$  B.) by boiling with direct steam, the final weight being 117 kilos. This solution was then oxidised with a mixture of 14 kilos. of nitric acid ( $29^{\circ}$  B.) and 28 kilos. of hydrochloric acid ( $20^{\circ}$  B.). The whole is again boiled, and gives finally 225 kilos. of a 26.5 per cent. ferric chloride solution ( $20^{\circ}$  B.), corresponding to 60 kilos. of solid salt, at a cost of about 1.25d. per kilo.

A sulphonic acid of the above dihydroxynaphthalene has also been patented, and is capable of yielding dyestuffs. The starting point for this acid is Eikonogen, which is the sodium salt of 1,2,3'-amidonaphthol sulphonic acid. It is obtained by reducing 1,2,3'-nitronaphthol sulphonic

acid with tin salt and crystallising it from a concentrated sodium bisulphite solution. For use as a photographic developer it is ground with sodium metabisulphite, to prevent oxidation. The following method is given for converting it into the dihydroxynaphthalene sulphonic acid. 500 grms. of Eikonogen dissolved in 2 litres of water are cooled with ice to 5° C., precipitated with 291 grms. of sulphuric acid, and oxidised at a low temperature with 1,460 grms. of a 31 per cent. lead peroxide paste. The yellowish-orange solution is decanted from the lead sulphate and added to 10 litres of an aqueous solution of sulphurous acid. On evaporation, the ammonium salt of  $\beta$ -naphthohydroquinone crystallises out, and weighed, when dry, 450 grms. When combined, in presence of calcium acetate, with various diazotised aromatic amidosulphonic acids, it gives dyestuffs producing bluish shades on chrome-mordanted wool; but since they dye unevenly, and give, with the exception of that from  $\beta$ -naphthylamine- $\beta$ -sulphonic acid (Brönner), duller shades than those from the non-sulphonated dihydroxynaphthalene, they have not been produced on a manufacturing scale.—T. A. L.

## PATENTS.

*Dyeing Extracts used for Dyeing Purposes; Impts. in or relating to Machinery or Apparatus employed for.* S. Smithson, Heckmondwike. Eng. Pat. 19,591, Sept. 4, 1896.

The essential feature of this invention is a hollow, steam-heated, metallic cylinder slowly revolving in a trough containing the extract; the adhering film being thus dried, is removed from the revolving cylinder by scrapers.—I. S.

*Dyes "Blues, Blacks", An Improved Manufacture of.* H. R. Vidal, Paris, France. Eng. Pat. 13,093, June 3, 1896.

The patentee describes the stages in which he considers the reaction of sulphur on substances like hydroquinone and  $p$ -amidophenol takes place. Sulphur reacting on  $p$ -amidophenol yields  $p$ -dihydroxythiazine, together with one molecule of ammonia, which, in presence of the sulphur, effects a further condensation, and generates  $p$ -dihydroxytetraphenethiazine—

The same compound can be obtained from hydroquinone by acting on it with ammonia and sulphur.

Analogous compounds, in which the hydroxyl is totally or partially replaced by the amino group, are obtained by the action of sulphur on  $p$ -diamidotriazine or on  $p$ -hydroxyamidotriazine. Thus,  $p$ -diamidotetraphenethiazine, a black dyestuff, soluble with difficulty in alkaline sulphides, can be obtained by heating in an autoclave to 210–240° C., 24 kilos. of  $p$ -amidophenol, 6.4 kilos. of sulphur, and 1.5 kilo. of phospham (P.N.11). The amido-hydroxy derivative is obtained by heating together at the same temperature, 12 kilos. of  $p$ -amidophenol, 12 kilos. of  $p$ -phenylene diamine, and 6.2 kilos. of sulphur. Furthermore, a class of dyestuffs is described, intermediate between the thiazines and tetraphenethiazines, which are the triphenethiazines. A mixture of hydroquinone 11 kilos.,  $p$ -dihydroxythiazine 23 kilos., phospham 1.5 kilo., and sulphur 3.2 kilos., is heated to 210–240° C. These substances form blue to black dyestuffs for vegetable or animal fibres, from baths reduced by sulphides or alkaline sulphites or bisulphites. They may also be obtained by the action of sulphur on

$p$ -diamidotriphenylamine or  $p$ -hydroxyamidotriphenylamine, or by the action of sulphur and ammonia or phospham on  $p$ -dihydroxydiphenylamine, or upon  $p$ -hydroxyamidodiphenylamine. If phospham (1.5 kilo.) alone be allowed to react at 210–240° C. on two molecular proportions (23 kilos.) of  $p$ -dihydroxythiazine, a substance having the following constitution is obtained:—

and, by varying the components, other analogously constituted compounds are formed. (See also Eng. Pats. 3612 of 1895, 16,449 and 18,489 of 1896; this Journal, 1896, 30, and 1897, 608 and 437.)—T. A. L.

*Black Colouring Matter, Production of.* S. Pitt, Sutton, Surrey. From L. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 19,831, Sept. 8, 1896.

The dyestuff is obtained from  $m$ -dinitrophenol ( $\text{OH} : (\text{NO}_2)_2 = 1:2:4$ ) by heating it with alkaline sulphides and sulphur, the following quantities being taken:—25 kilos. of  $m$ -dinitrophenol, 125 kilos. of sodium sulphide, and 50 kilos. of sulphur are heated within an hour to 160° C. The temperature is then gradually raised to 160° C., and maintained thereat until the melt solidifies, which takes place in 2–3 hours. The melt, after breaking up, may then be used directly, or it may be carefully neutralised with hydrochloric acid, filtered off, and left as a paste, or dried. In this latter case the dyestuff must be dissolved in soda lye or sodium sulphide before use. It dyes black directly on unmordanted cotton. If less sulphur be used, a brown colour is obtained.—T. A. L.

*Compounds of the Series of the Indoxyl Acids and of Dyestuffs of the Indigo Series, A Process for the Manufacture of.* R. Blank, Berlin. Eng. Pat. 19,946, Sept. 9, 1896.

The process consists in converting chloro- or bromo-malonic acid or their esters by heating with aromatic amines into substituted amido-malonic acids or their esters, which, when heated, are converted into indoxyl acids and esters. These compounds, on exposure to air in an alkaline solution, are converted into the corresponding indigos. The following example gives the quantities employed, starting from  $p$ -toluidine. An alcoholic solution containing 9 kilos. of  $p$ -toluidine is mixed with 10 kilos. of bromo-malonic acid ester and allowed to stand 2 days, after which the melt is heated on the water-bath for 2 hours. About 50 litres of water and some hydrochloric acid are then added, and the insoluble oil is separated and cooled, when it crystallises. After purification, the  $p$ -toluidino-malonic acid ester melts at 55° C., and is easily soluble in the ordinary organic solvents. The acid can be obtained from this by saponification with alkalis or alkaline earths, or it may be produced directly as follows:—A solution of 6.5 kilos. of chloro-malonic acid in alcohol is mixed with an alcoholic solution of 10 kilos. of  $p$ -toluidine, heated for an hour on the water-bath, and after distilling off the alcohol, the residue is extracted with dilute hydrochloric acid. The residue is re-crystallised from dilute alcohol and forms colourless crystals which melt with decomposition at 117° C. When the ester is heated to about 250–255° C., alcohol is split off and the  $p$ -tolyl-indoxyl acid ester is crystallised from alcohol, forming colourless crystals melting at 156° C. It dissolves in alkalis, and can be precipitated by carbonic acid from the solution. On boiling it with alkalis or alkaline earths, salts of  $p$ -tolylindoxyl acid are obtained, whilst on heating it with concentrated sulphuric acid on a water-bath, it yields sulphonic acids of  $p$ -tolyl indigo. Paratolylindoxyl acid is obtained by heating sodium  $p$ -toluidino-malonate with four times its weight of sodium hydrate to 300–350° C. for about five minutes with continual agitation. The melt is then cooled and stirred into cold, very dilute sulphuric acid, when the new acid separates out as a bluish-white powder melting at 117° C. Its alkaline solution is readily oxidised in the air, depositing  $p$ -tolyl indigo. This product is blue,

in the form of powder, but has a reddish colour in larger lumps. It gives blue solutions in alcohol, aniline, and sulphuric acid, and its paraffin solution is reddish-violet when hot, and bluish-violet when cold. The formation of the indigo may of course take place upon the fibre.

—T. A. L.

*Basic Disazo Colouring Matters, Manufacture of.* O. Imray, London. From "The Farbwerke vorm. Meister, Lucius, and Brüning," Höchst a Main, Germany. Eng. Pat. 19,976, Sept. 9, 1896.

THE base employed for the production of these dyestuffs is *p*-amidobenzylamine or one of its derivatives alkylated in the side chain. The product, after diazotisation, is allowed to act on an azo dyestuff capable of combining, or else the amido-azo dyestuffs produced from the amidobenzylamine derivatives and primary amines are diazotised and combined with phenols or amines. 100 kilos. of the zinc chloride double salt of *p*-amidobenzyl-diethylamine are dissolved in 60 kilos. of concentrated hydrochloric acid diluted with water. A solution of 18 kilos. of sodium nitrite is then added and the whole is combined with 37 kilos. of  $\alpha$ -naphthylamine, 150 kilos. of sodium acetate, and 70 kilos. of hydrochloric acid. After standing some hours the solution is again diazotised by adding 200 kilos. of hydrochloric acid and the necessary amount of the nitrite, and is then combined with 37 kilos. of  $\beta$ -naphthol in an alkaline solution. The solution is finally boiled to complete the reaction, when the dyestuff is filtered off. By adding hydrochloric acid, it is converted into a salt soluble in water. No reference is made to the shades obtainable, but the dyestuffs are said to be suitable for dyeing mixed goods from an acid bath.—T. A. L.

*Para-Amido-Alpha-Naphthol and of Colouring Matters derived from them, Manufacture of Derivatives of.* O. N. Witt, Berlin, Germany. Eng. Pat. 20,676, Sept. 18, 1896.

THE subject matter of this specification has already been abstracted (Ber. 29, 2945; this Journal, 1897, 134). In addition, the patentee states that naphthacetyl (*p*-acetamido- $\alpha$ -naphthol) may also be obtained from diacetyl-*p*-amido-naphthol by stirring this product to a thin paste with strong caustic soda or potash and heating on the water-bath until a clear solution is formed. The naphthacetyl is then precipitated on adding an acid.—T. A. L.

*Colouring Matters [Saccharo-fluorescein]. Impts. in and relating to the Production of.* G. B. Ellis, London. From "La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier," Lyons, France. Eng. Pat. 21,196, Sept. 24, 1896.

THESE dyestuffs are allied to fluorescein, and are obtained by condensing resorcinol with saccharine (anhydro-*o*-sulphamine benzoic acid). 22 kilos. of resorcinol are heated with 18 kilos. of pure saccharine for seven hours to 200°–220° C. After cooling, the melt is extracted with cold dilute sodium carbonate, and the dyestuff is precipitated with acid. It is purified by dissolving in alcohol and precipitating with water, when, after washing and drying, it forms a brown resinous product. The saccharo-fluorescein thus produced may be obtained in a pure state by converting it into its acetyl derivative, which is subsequently hydrolysed. The product, obtained as above, is boiled with three times its weight of acetic anhydride under a reflux condenser. The acetyl derivative is precipitated with alcohol, and separates from glacial acetic acid on adding alcohol, as a crystalline powder, melting at 286° C. When boiled with alcoholic caustic soda it dissolves on hydrolysis, and the solution, after dilution, is acidified with acetic acid. Saccharo-fluorescein separates out, and may be crystallised from alcohol. The pure product melts at 267° C. Like ordinary fluorescein, it may be converted into halogen derivatives, of which the following is an example:—10 kilos. of saccharo-fluorescein are dissolved in 50 kilos. of alcohol, and 11 kilos. of bromine are gradually added at about 40° C.; 3 kilos. of sodium chlorate in 3 litres of water are then run in, and the bromine compound begins to separate in small reddish-brown crystals. The crystalline

powder thus obtained is insoluble in water and alcohol, but soluble in alkalis with a red colour. It has similar properties to eosine, but dyes a bluer shade. The isosaccharo-fluorescein is soluble in alkalis to a violet-red solution.—T. A. L.

*New Black Merdant-dyeing Colouring Matter, Manufacture of.* C. D. Abel, London. From "The Actien-Gesellschaft für Anilin-Fabrikation," Berlin, Germany. Eng. Pat. 21,437, Sept. 28, 1896.

THE following process is employed:—22.1 kilos. of sodium picramate ( $1,2,4,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,28,29,30,31,32,33,34,35,36,37,38,39,40,41,42,43,44,45,46,47,48,49,50,51,52,53,54,55,56,57,58,59,60,61,62,63,64,65,66,67,68,69,70,71,72,73,74,75,76,77,78,79,80,81,82,83,84,85,86,87,88,89,90,91,92,93,94,95,96,97,98,99,100,101,102,103,104,105,106,107,108,109,110,111,112,113,114,115,116,117,118,119,120,121,122,123,124,125,126,127,128,129,130,131,132,133,134,135,136,137,138,139,140,141,142,143,144,145,146,147,148,149,150,151,152,153,154,155,156,157,158,159,160,161,162,163,164,165,166,167,168,169,170,171,172,173,174,175,176,177,178,179,180,181,182,183,184,185,186,187,188,189,190,191,192,193,194,195,196,197,198,199,200,201,202,203,204,205,206,207,208,209,210,211,212,213,214,215,216,217,218,219,220,221,222,223,224,225,226,227,228,229,230,231,232,233,234,235,236,237,238,239,240,241,242,243,244,245,246,247,248,249,250,251,252,253,254,255,256,257,258,259,260,261,262,263,264,265,266,267,268,269,270,271,272,273,274,275,276,277,278,279,280,281,282,283,284,285,286,287,288,289,290,291,292,293,294,295,296,297,298,299,300,301,302,303,304,305,306,307,308,309,310,311,312,313,314,315,316,317,318,319,320,321,322,323,324,325,326,327,328,329,330,331,332,333,334,335,336,337,338,339,340,341,342,343,344,345,346,347,348,349,350,351,352,353,354,355,356,357,358,359,360,361,362,363,364,365,366,367,368,369,370,371,372,373,374,375,376,377,378,379,380,381,382,383,384,385,386,387,388,389,390,391,392,393,394,395,396,397,398,399,400,401,402,403,404,405,406,407,408,409,410,411,412,413,414,415,416,417,418,419,420,421,422,423,424,425,426,427,428,429,430,431,432,433,434,435,436,437,438,439,440,441,442,443,444,445,446,447,448,449,450,451,452,453,454,455,456,457,458,459,460,461,462,463,464,465,466,467,468,469,470,471,472,473,474,475,476,477,478,479,480,481,482,483,484,485,486,487,488,489,490,491,492,493,494,495,496,497,498,499,500,501,502,503,504,505,506,507,508,509,510,511,512,513,514,515,516,517,518,519,520,521,522,523,524,525,526,527,528,529,530,531,532,533,534,535,536,537,538,539,540,541,542,543,544,545,546,547,548,549,550,551,552,553,554,555,556,557,558,559,560,561,562,563,564,565,566,567,568,569,570,571,572,573,574,575,576,577,578,579,580,581,582,583,584,585,586,587,588,589,590,591,592,593,594,595,596,597,598,599,600,601,602,603,604,605,606,607,608,609,610,611,612,613,614,615,616,617,618,619,620,621,622,623,624,625,626,627,628,629,630,631,632,633,634,635,636,637,638,639,640,641,642,643,644,645,646,647,648,649,650,651,652,653,654,655,656,657,658,659,660,661,662,663,664,665,666,667,668,669,670,671,672,673,674,675,676,677,678,679,680,681,682,683,684,685,686,687,688,689,690,691,692,693,694,695,696,697,698,699,700,701,702,703,704,705,706,707,708,709,710,711,712,713,714,715,716,717,718,719,720,721,722,723,724,725,726,727,728,729,730,731,732,733,734,735,736,737,738,739,740,741,742,743,744,745,746,747,748,749,750,751,752,753,754,755,756,757,758,759,760,761,762,763,764,765,766,767,768,769,770,771,772,773,774,775,776,777,778,779,780,781,782,783,784,785,786,787,788,789,790,791,792,793,794,795,796,797,798,799,800,801,802,803,804,805,806,807,808,809,810,811,812,813,814,815,816,817,818,819,820,821,822,823,824,825,826,827,828,829,830,831,832,833,834,835,836,837,838,839,840,841,842,843,844,845,846,847,848,849,850,851,852,853,854,855,856,857,858,859,860,861,862,863,864,865,866,867,868,869,870,871,872,873,874,875,876,877,878,879,880,881,882,883,884,885,886,887,888,889,890,891,892,893,894,895,896,897,898,899,900,901,902,903,904,905,906,907,908,909,910,911,912,913,914,915,916,917,918,919,920,921,922,923,924,925,926,927,928,929,930,931,932,933,934,935,936,937,938,939,940,941,942,943,944,945,946,947,948,949,950,951,952,953,954,955,956,957,958,959,960,961,962,963,964,965,966,967,968,969,970,971,972,973,974,975,976,977,978,979,980,981,982,983,984,985,986,987,988,989,990,991,992,993,994,995,996,997,998,999,1000$ ) are diazotised, and the solution is run into a solution of 22.3 kilos. of 1,3'-naphthylamine sulphonic acid acidified with acetic acid. The azo compound thus formed is rediazotised by means of hydrochloric acid and sodium nitrite, and the diazo compound which separates, is stirred into a caustic alkaline solution of 14.4 kilos. of  $\beta$ -naphthol. The dyestuff separates as a bluish-green precipitate, and is filter-pressed and dried. It dissolves in water to a bluish-violet solution and in sulphuric acid with a blackish-violet colour. It dyes wool from an acid-bath blackish-violet shades, which, on treatment with chromium salts, are converted into dark black, perfectly fast to washing and light. The nature of the dyestuff is not altered if 1,2'-naphthylamine sulphonic acid, or a mixture of this with the 1,3' acid, be employed.—T. A. L.

*New Violet Mono-azo Dyestuffs for Wool, Dyeing a Fast Brown by Oxidation with Chrome: Manufacture of.* O. Imray, London. From "The Farbwerke vorm. Meister, Lucius, and Brüning," Höchst a Main, Germany. Eng. Pat. 23,175, Oct. 19, 1896.

DIAZO compounds of 1,1'-naphthol sulphonic acids when combined with  $\alpha$ -naphthylamine, its alkyl and aliphyl derivatives in an acid solution, yield violet dyestuffs, which, on treatment with chromates or chromic acid, are converted into browns very fast to milling and light. For instance, 2.39 kilos. of 1,1'-4'-amidonaphthol sulphonic acid, together with 0.42 kilo. of caustic soda, are dissolved in about 90 litres of water. A strong solution containing 0.69 kilo. of sodium nitrite is then added, and the whole is allowed to run into an ice-cold solution containing 0.92 kilo. of hydrochloric acid. The yellowish-brown precipitate of the diazo compound separates out, and is added to 1.43 kilo. of  $\alpha$ -naphthylamine dissolved in 30 litres of water, together with the calculated quantity of hydrochloric acid at a temperature of about 25° C. 3 kilos. of crystallised sodium acetate are added, and finally, in order to complete the reaction, the whole is heated to 80° C.; 2.2 kilos. of sodium carbonate are then added, when the dyestuff is converted into the sodium salt. It forms, when dry, a greenish-black powder, sparingly soluble in cold, more easily in hot water, and having dyeing properties as above mentioned. Other amidonaphthol acids which may be employed are amidonaphthol disulphonic acid II, amidonaphthol sulphonic acid S, 1,1'-4'-amidonaphthol sulphonic acid, 1,1'-3'-amidonaphthol sulphonic acid, 1,1'-3'-amidonaphthol sulphonic acid, or 1,1'-2'-amidonaphthol sulphonic acid. The combination with  $\alpha$ -naphthylamine, or its derivatives may also take place in an alcoholic solution.—T. A. L.

*New Colour Base, and of Colouring Matters therefrom [Red]: Production of.* I. Levinstein and Levinstein. Ltd., Manchester. Eng. Pat. 25,725, Nov. 16, 1896.

THE base referred to is a dichlorobenzidine, which is obtained by the action of bleaching powder on diacetylbenzidine dissolved in sulphuric acid, and subsequent hydrolysis of the product by boiling it with hydrochloric acid. The following quantities are employed:—26.8 kilos. of diacetylbenzidine are dissolved in 3 kilos. of concentrated sulphuric acid, and the solution is poured into ice-cold water. The mixture, being kept at a low temperature, has added to it, with constant agitation, sufficient of a 10 per cent. bleaching powder solution to form a dichlorobenzidine. The temperature is then raised to 40° C., and after standing 12 hours, the new dichlorodiacetylbenzidine is filtered off as a yellowish precipitate. In order to hydrolyse it, it is boiled with 3–4 times its weight of 20 per cent. hydrochloric acid; and the solution, on cooling, deposits dichloro-

benzidine hydrochloride, which is converted into the base in the well-known manner. It may also be chlorinated by suspending the same quantity of the diacetyl derivative in 200 litres of brine, introducing some iron wire to act as a carrier, and passing chlorine through so long as it is absorbed, the liquor meanwhile being cooled externally. For the preparation of a dyestuff, 26 kilos. of the base are dissolved in 300 litres of water containing 70 kilos. of hydrochloric acid (18° B.), and diazotised cold with an aqueous solution of 14 kilos. of sodium nitrite. The tetrazo compound produced is run into an aqueous solution of 50 kilos. of sodium naphthionate (100 per cent.), containing sufficient sodium acetate to neutralise the mineral acid. The dyestuff separates as a red precipitate, and after stirring 12 hours it is made alkaline, heated to 80° C., salted out, filter-pressed, and dried. It dyes unmodified cotton bluish-red, comparatively fast to acids. By employing  $\beta$ -naphthylamine sulphonic acid (Brönnert) in place of the naphthionic acid, a bright bluish-red is obtained, which is fast to organic acids. In general, the dyestuffs which are obtained from this base, are much bluer and faster to acids than the corresponding derivatives from tetrazodiphenyl or tetrazoditolyl.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Soupling of Half-Silk Goods.* Textile Colorist (U.S.), 19, 140—141.

THE soupling process is not applied to piece-goods consisting entirely of silk, since the strength and ductility of the fibre are affected thereby. But in the case of half-silk goods, soupling in the piece offers several advantages. In such goods the silk is generally used in the form of "grège" or untwisted threads, and only shows on the surface of the material, and, when soupled, the silk swells and entirely covers the surface; it also becomes easier to dye, while the strength of the fibre is very slightly impaired. The cotton or wool at the same time acquires a "screopy" silk-like handle.

For wool-silk goods, soupling is effected as follows:—The material is worked for 1—2 hours in a weak, lukewarm soda solution, and rinsed. After crabbing, it is then treated in a bath containing 8 per cent. of sulphuric acid (6° B.) and 3 per cent. of tartar, raising to the boil in an hour and maintaining at that point for 1—2 hours. For white and pale shades the goods are stove; for dark colours this is omitted, and dyeing with acid dyestuffs at once follows. Dyeing on the tentering-frame and lustring, complete the operation.

Cotton-silk goods are scoured in a weak soap-bath, washed, soupled with 2 per cent. of bisulphite of soda, 3 per cent. of tartaric acid, and 3 per cent. of tartar, washed, dyed, and dried on a cylinder machine. Hot pressing, &c. may follow according to the finish required.—R. B. B.

*Acid Fulling.* [Woolens and Felt.] Textile Colorist (U.S.), 19, 143—144.

THE process of fulling with acids has not made great headway, and it is now declared by H. Richard and others that it should be entirely abandoned. The defects in the process leading to this conclusion are, the necessity of cleansing the goods before fulling, far more carefully than when soap is used, the tendency of white goods to assume a dirty yellow cast, and the injurious effect on the health of the workmen. It is also stated that in material fulling with acid, the felt is spongy and coarse, and the goods possess a raw, translucent, and unfinished appearance. The process is at the best only suited for blankets and goods of inferior quality.—R. B. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Wool and Cotton, The Absorption of Magnesium and Aluminium Chlorides by.* F. Breinl and C. Hanofsky. Chem. Zeit. 21, 553—564.

IN a previous paper on the "carbonisation" of wool (this Journal, 1893, 36—37), the authors have shown that the

hydrolysing action of aluminium and magnesium chlorides on the vegetable impurities accompanying wool is due to the free acid liberated from these salts during the process of drying. They have now made the further observation that during the carbonising process, the salts absorbed by cotton or other vegetable bodies only are decomposed, whilst pure wool that has been impregnated with magnesium chloride does not liberate any hydrochloric acid when heated to 140°—150° C., and with neutral aluminium chloride, traces only, if any.

This conclusion has been called in question by Knecht, Rawson, and Loewenthal in their "Handbook on Dyeing," who suggest as an explanation that the absorbent power of wool for these salts in cold solutions is probably very slight, and hence only small quantities of acid are liberated during the subsequent drying process.

The authors have now tested this theory by a series of experiments on the relative absorbent powers of wool and cotton for these salts. Their results show that under like conditions wool and cotton absorb, even from cold solutions, almost identical quantities of aluminium and magnesium chlorides.

They have found, however, that an excess of hydrochloric acid is always present in the wool over that necessary to form aluminium chloride, and consequently over the alumina also absorbed, which leads the observers to the conclusion that wool does not absorb equivalent quantities of base and acid from solutions of aluminium salts.—I. S.

*Albumin, A New Preparation of.* Compagnie Parisienne de Couleurs d'Aniline. Fr. Pat. 256,981, 1896.

FOUR kilos. of the white of eggs are mixed with 25 grms. of 40 per cent. formaldehyde, and after allowing the mixture to rest for several days, water is added, and the formaldehyde is expelled by boiling. The mass is then filtered, and the water evaporated in a vacuum pan at a low temperature to dryness. The new product is precipitated by acids and alcohol, is redissolved by water, but is not precipitated by alkalis. The product is said to possess all other prominent characteristics of albumin.—I. S.

*Insoluble Azo Dyes on Wool.* M. Goldovsky. Färber Zeit. 8, 184.

PARANITRANILINE Red and the other insoluble azo dyes have hitherto found no application in the dyeing of wool, since the alkaline solutions used, act injuriously upon the fibre. The author declares, however, that these colours can be applied, without injury to wool, by either of the two following methods:—

(a.) The wool is dyed yellow in a hydrochloric acid solution of paranitraniline, and diazotised in the usual manner; it thus acquires a dull brownish-yellow tint. The diazotised wool is then passed into a solution of  $\beta$ -naphthol in caustic soda, after which it is washed in acidulated water and finally in ordinary water.

(b.) The wool is worked in a solution of diazotised paranitraniline, washed, developed in  $\beta$ -naphthol, and twice washed, as in the former process.

The author states that useful fast colours are thus obtained with paranitraniline, metanitraniline, dianisidine, &c.—R. B. B.

*Commercial Egg Albumin, Estimation of.* P. Carles. J. Pharm. Chim. 1897, 6, [3], 102.

See under XXIII., page 767.

## PATENTS.

*Mixed or Parti-coloured Fabrics, Impts. in the Manufacture of.* H. Giesler, Melsheim, Germany. Eng. Pat. 28,376, June 3, 1896.

"THE manufacture of fabrics having the effects which have hitherto been produced in textile fabrics by weaving with coloured, parti-coloured, or (*vigueur*) 'mixed,' or fancy threads; the main feature of the said manufacture consisting in impressing or printing a design on the fabric, and then distorting the fibres by displacing, turning, or twisting them so that the sharp lines of the pattern are

destroyed, and a fabric having the appearance of a mixed woven fabric, or one formed from fibres dyed with various colours before weaving, is produced."—I. S.

*Hair or Fur, Impts. in Dyeing.* M. L. Kellogg, New York. Eng. Pat. 14,831, June 18, 1897.

HUMAN hair, or the fur of animals, is dyed by alternately treating the same with "an aqueous solution of an ammonio-salt of metal," preferably "ammonio-citrate of nickel," and a suitable mordant, such as pyrogallol acid (pyrogallol).—I. S.

*Vessels [Steam Jacketed] for Dyeing Purposes, Impts. in and connected with.* B. Lee, Leeds. Eng. Pat. 20,846, Sept. 21, 1896.

THE improved vessel is made of iron, and is provided with a steam jacket in which the heat of the exhaust steam from an engine is to be utilised. The vessel may be lined with lead "or other suitable material."—I. S.

*Printing Multicoloured Designs upon Fabrics and Warp Chains, Process and Apparatus for.* C. Dratz, Brussels. Eng. Pat. 17,692, Aug. 10, 1896.

THE essential feature of this invention is a printing roller, "constituted preferably by a cylinder of wood or metal upon which slides a sleeve carrying the design to be printed, made up of a great number of small blocks of solid colouring matter, conveniently arranged, in order to realise a composition in a manner analogous to type-setting," driven at a convenient speed, and pressing upon the wetted warp threads in the act of weaving.—I. S.

*Dyeing or Colouring and Sizing of Yarn, and in Apparatus therefor; Impts. in or connected with the.* J. Tattersail, Enschede, Netherlands. Eng. Pat. 21,765, Oct. 1, 1896.

WHEN yarn has to be both sized and dyed, the colouring matter is generally added to the size. This method has the disadvantage that when a different colour is required, the machine has to be carefully cleaned, and the remainder of the coloured size has to be thrown away, inasmuch as it cannot be preserved for future use. To remedy these defects the inventor inserts a separate colour trough between the size or sow box and the drying cylinder, provided with a pair of squeezing rollers, the lower of which is partially immersed in the dye-bath. When yarn has only to be sized and not coloured, the top roller of the dye-box is raised, so that the yarn can pass freely between the top and bottom rollers without receiving any colouring matter.—I. S.

*Mordanting Agent and Process for Vegetable Fibres, An Improved.* [Antimony Lactate.] C. H. Boehringer Sohn, Niederlingheim on the Rhine, Germany. Eng. Pat. 22,522, Oct. 10, 1896.

THE inventor has observed that antimony lactate, produced by the direct combination of antimony oxide and lactic acid, remains stable only in the presence of a large excess of acid. This lactate is unsuitable for the mordanting of cloth prepared with tannin, because from the strongly acid solution only small quantities of antimony oxide are precipitated on the fibre. By the following method a double lactate of antimony, suitable for mordanting without the addition of acid, may be prepared, which yields the whole of its antimony to the tannic acid on the fibre:—

One molecule of antimony oxide is digested with the aid of heat with two molecules of "acid lactate of calcium," which produces "a clear solution of antimonic oxide." This solution is used in the usual way on the tannin-prepared cloth.—I. S.

*Dyeing of Combing Ribbons or Slivers or the like, Impts. relating to the Method and Machinery for Partial or Complete.* F. Desormont, Tourcoing, France. Eng. Pat. 13,712, June 3, 1897.

THE sliver is wound on to a reel of special construction, provided with transverse rods and plates at stated distances. Plates are placed on the top of the wound-up sliver opposite to the plates underneath it, and secured to the latter by means of bolts. The reel is then introduced into the dye

liquor and revolved until the wool is dyed of the required shade. The parts compressed between the plates will then remain undyed.—I. S.

*Myrabolams, Obtaining Extracts therefrom; Impts. in or relating to Machinery or Apparatus for Treating.* S. Smithson, Heckmondwike. Eng. Pat. 12,399, May 19, 1897.

A REVOLVING tank fitted with agitating plates and steam pipes, for the purpose of extracting myrabolams and like materials of a hard gummy nature.—C. O. W.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Caustic Potash and Soda, Commercial, Purified by Alcohol.* [Analysis.] E. Murmann. *Zeits. Anal. Chem.* 36, 379–380.

COMMERCIAL potassium or sodium hydrate purified by alcohol still usually contains small quantities of copper, lead, and iron, as well as alumina and silica.

Hydrogen sulphide removes them easily. To the greater portion of the warm solution sulphuretted hydrogen water is added so long as the colour darkens, but avoiding excess. A portion is drawn from time to time through a hardened filter until the filtrate is no longer coloured brown by either hydrogen sulphide or lead solution. Any slight excess of sulphide is removed by adding the remainder of the alkali solution, or rendered inert by hydrogen peroxide. The remaining impurities consist of a little silica and alumina. —L. J. de W.

## PATENTS.

*Condensing Nitrous Acid, or other Fumes or Vapour; Impts. in Means or Apparatus for.* J. L. Dobell, Harlesden, Middlesex. Eng. Pat. 18,137, Aug. 15, 1896.

A VERTICAL tubular standard or chamber, enlarged into a well below, into which a depending partition dips, acting as a seal,—has apertures on the side, one immediately above the well, and the other near the top of the chamber, from which large pipes pass, of which the lower one slopes upwards to enter the bottom of a covered feed chamber, while the upper pipe enters the side of the same chamber, so that vapours entering a slightly inclined injector traversing the standard and projecting into the lower tube, are carried through the feed chamber and then through the upper pipe, into the upper part of the standard, which is provided at the top with an exit pipe for carrying off any uncondensed vapours. The two long pipes are charged from the feed chamber with broken pumice stone, and as the upper tube is slightly inclined, and the lower tube much more so, the liquid of condensation flows into the well. If nitrous acid fumes are to be recovered as nitric acid, air and steam are injected with the fumes. Several of the condensing apparatus are shown connected to form a series.—E. S.

*Bleaching Powder, Impts. in the Treatment of [by Compression], to preserve it from Loss of Active Chlorine.* J. Y. Johnson, London. From Chemische Fabrik Elektron "Actien Gesellschaft," Frankfurt-on-Main, Germany. Eng. Pat. 19,222, Aug. 31, 1896.

BLEACHING powder is compressed sufficiently to occupy a bulk approaching to, but not less than that of an equal weight of water. Bleaching powder thus treated may be packed in drums made of thin sheet metal, is not appreciably liable to change, and admits of ready breaking up into a powder for use. Higher compression than that stated is objectionable. Reference is made to Eng. Pat. 5673, 1886 (this Journal, 1887, 367).—E. S.

*Utilising the Residual Products [Caustic Alkali Solution of Zinc] obtained in the working of certain kinds of Voltaic Batteries, Impts. in.* W. Walker, jr., and F. R. Wilkins, Birmingham, Jabez Jones and Joseph Jones, Smethwick. Eng. Pat. 19,308, Sept. 1, 1896.

See under XI. A., page 745.

*Cyanides, Improved Means for Manufacturing and Recovering from Coal-Gas, and Apparatus therefor.* G. P. Lewis, Catford, Kent, and R. A. Cripps, Hayward's Heath, Sussex. Eng. Pat. 20,883, Sept. 21, 1896.

THE gas to be treated enters a rectangular casing, containing several superposed compartments, at the bottom, and is led by a described arrangement through a series of inverted troughs, having serrated edges, so as to bubble up through a washing liquor supplied to the top compartment, and overflowing successively into each compartment below, until it is led into a receptacle from the bottom. The gas traverses the troughs in each compartment, and is led away from the top. The washing liquid in each compartment is kept agitated by a revolving screw propeller. When it is desired to recover the cyanogen of the gas as a sulphocyanide, solution of an alkali or alkali-earth hydrate is sulphuretted, either by passing through it hydrogen sulphide, or by addition of the liquid condensed from the "waste gases" in the manufacture of ammonium salts, and is used as the washing liquor, after addition of flowers of sulphur and exposure to the air. A small proportion of oxygen in the gas to be thus treated, is desirable. To obtain ferrocyanides, iron sulphide is suspended in the alkaline washing liquor. Prussian blue is obtained by using crude gas liquor with iron sulphide in suspension; the ammonium ferrocyanide solution obtained, is run through ammonia stills and treated with lime, and the effluent containing calcium ferrocyanide is treated for the recovery of Prussian blue by the method described in Eng. Pat. 5184, 1896 (this Journal, 1896, 239).—E. S.

*Baking Powders, Impts. in.* F. Dietrich, Riegel, Germany. Eng. Pat. 20,891, Sept. 21, 1896.

ACID ammonium phosphate ( $\text{NH}_4\text{H}_2\text{PO}_4$ ) is substituted, wholly or in part, for acid potassium tartrate in baking powders; and one or more "retarding substances," such as calcium carbonate, magnesium carbonate, or dicalcium hydrogen phosphate, are introduced, to prevent premature or too rapid evolution of carbonic acid. In one of the examples given, stated proportions are used of acid ammonium phosphate, sodium bicarbonate, calcium carbonate, or magnesium carbonate, and of a filling substance, such as corn starch. Generally stated, the baking powder consists, "in the main, of pure crystallised acid ammonium phosphate and sodium bicarbonate, to which distinctly characterised acid or basic substances producing carbonic acid are still added, or both substances together."—E. S.

*Copper Sulphate, Impts. in the Production of.* T. Savage, Birmingham. Eng. Pat. 21,953, Oct. 3, 1896.

COPPER is treated in a tank heated by steam pipes, with sulphuric acid of sp. gr. 1.20, to which later there is added about half its weight of sodium nitrate. The solution of the copper is said to be effected much more rapidly than when dilute sulphuric acid alone is employed, as in the ordinary process. When the solution is saturated with copper, it is taken to a lead-lined vat having lead hangers, for crystallisation.—E. S.

*Double Chloride of Aluminum and Soda, A New Process of Manufacture of.* The Compagnie Générale L'Alumine Exploitation des Brevets F. Raynaud, Société Anonyme, Brussels, Belgium. Eng. Pat. 12,265, May 18, 1897. (Under Internat. Convention.)

A MIXTURE of ferruginous bauxite, sodium chloride, and carbon is moulded into porous blocks, which are heated to redness in suitable retorts, through which hydrogen sulphide is passed. When the sulphuration is complete, a current of air is substituted for that of the hydrogen sulphide, when sodium-aluminum chloride distils over and is collected. The processes are repeated in the same order as often as may be necessary to exhaust the ore. The iron is sulphuretted in the first, and oxidised in the second process. The sodium sulphate formed undergoes slight reduction.—E. S.

*Ammonium Bichromate, A New Process for the Production of.* W. Majert, Grönuu, Germany. Eng. Pat. 13,551, June 1, 1897.

MOLECULAR proportions of ammonium chloride and of sodium bichromate or calcium bichromate are dissolved in three parts of hot water; ammonium bichromate separates on cooling, and may be recovered by centrifugal action. According to a second process, solutions of calcium bichromate and of ammonium sulphate, each in 5 parts of hot water, and in equivalents, are mixed, and the mixture is boiled until calcium sulphate separates in a crystalline form. Ammonium bichromate is then crystallised out of the concentrated filtered solution; or, for a less pure salt, the latter may be dried.—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

### PATENT.

*Gas Furnaces and Muffles, Combined, Self-Producing, for Use in Enamelling Metallic Articles; Impts. in.* T. and A. Preece, Wolverhampton. Eng. Pat. 19,800, Sept. 8, 1896.

THE gas from an ordinary producer-furnace is passed over a brick arch into a flue running under the muffle (which is one designed for use in enamelling metallic articles), and opening at one side into a number of lateral passages leading, *via* a series of upright flues, into an arched flue over the muffle. This arched space is constricted on the opposite side to prevent the gases from escaping too freely through the descending flues there situated, and leading to the chimney. To secure equalisation of heat in the bottom flue, the lateral openings decrease in size towards the furnace end of the muffle. A series of air-flues keeps the firebrick arch and the bricks at the bottom and sides of the gas flues cool, the heated air passing into the arched flue and there producing intense combustion.—C. S.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Tiles and Brickwork, Efflorescence on.* Dingler's Polyt. J. 1897, 305, 8.

AN investigation has recently been carried out by Hans Günther (Baumaterialienkunde, 24 and 25, 385) into the cause and prevention of the dry efflorescence sometimes seen upon tiles and brickwork. This is usually ascribed to the formation of sulphates in the bricks or tiles, owing to the presence of sulphuric acid in the kiln gases. Sulphur dioxide, produced by the combustion of the pyrites in the coal, oxidises to sulphuric acid, and this attacks the bases present in the clay, more especially if lime be present in considerable quantity. Whether, as some suppose, this can take place only in the presence of water vapour, and therefore only during the smoky and incomplete stage of combustion, or whether it can also take place at a red heat, has been a disputed point. One thing, however, is certain, namely, that sulphuric acid cannot be formed in the presence of reducing gases; and this probably explains the superiority of the old intermittent kiln, in which there was frequently a deficiency of air, over the modern continuous ring-kiln, in which the air is always in excess.

The following experiments were made:—Samples of felspar, kaolin, and clay marl were heated to redness in air containing sulphur dioxide. The felspar was not affected at all, but both the kaolin and clay were attacked, with formation of calcium, sodium, and other sulphates. Further experiments, made with mixtures of clay and chalk, showed that the greater the proportion of lime, the larger was the quantity of sulphates formed. The author considers this proves that moisture is not essential to the formation of sulphates by the kiln gases, and that therefore their formation is not restricted to the smoky part of the kiln. Magnesia, when present in the clay, is also converted into sulphate, but, whereas calcium sulphate first reacts upon the alkaline salts in the mortar, magnesium sulphate effloresces unchanged on the surface of the bricks.

The author, however, believes the efflorescence to be due more to the pyrites in the clay itself than to that present in the fuel. Of 21 samples of brick and tile clays of different descriptions which were examined, every one

proved to contain pyrites. Further, quite considerable quantities of sulphates are formed when certain clays are burnt in air absolutely free from sulphur dioxide. Cubes made from clay containing 0.11 per cent. of  $\text{SO}_3$  were found, after heating to redness for seven hours in an atmosphere free from sulphur dioxide, to contain as much as 0.60 per cent.

In order to ascertain the behaviour of certain salts when ignited with clay, the following experiments were undertaken:—Six portions of clay were taken, and each mixed, in uniform proportions, with one of the following salts, *viz.*, (1)  $\text{Na}_2\text{SO}_4$ , (2)  $\text{K}_2\text{SO}_4$ , (3)  $\text{NaCl}$ , (4)  $\text{KCl}$ , (5)  $\text{BaCl}_2$ , and (6)  $\text{Na}_2\text{CO}_3$ . The several portions were shaped into tiles and burnt, the  $\text{SO}_3$  being determined both before and after burning. In (1) and (2) the  $\text{SO}_3$  diminished from 4.65 and 3.75 per cent. to 0.83 and 0.88 per cent. respectively; in (3) and (5) the chlorine disappeared altogether; and in (6) 0.16 per cent. of  $\text{SO}_3$  was found after burning.

In conclusion, the author recommends when the continuous method of burning is employed, that ferrum chloride and carbonate should be mixed with the clay used, to guard against soluble sulphates being formed.—H. H. B. S.

#### PATENTS.

*Unburnt Sand Brick.* A. Easterbrook, St. Austell. From T. T. Wood, St. Joseph City, Michigan, U.S. Eng. Pat. 17,635, Aug. 10, 1896.

The inventor claims an unburnt brick made from sand, cement, soluble silica, hydrochloric acid, and water in specified proportions.—V. C.

*Artificial Stone, Impts. in.* A. McLean, London. Eng. Pat. 19,419, Sept. 2, 1896.

In the preparation of paving stones from natural flagstone (which has a laminar structure), a large quantity of "waste" is produced. The inferior qualities of the stone are also practically waste. The inventor grinds these "waste" materials finely, and mixes with Portland cement, with the addition of water in the usual way. The concrete thus formed is pressed in moulds, making an artificial paving or "flag-stone."—V. C.

*Cements for Resisting the Action of Acids, Acid Vapours, and Heat; Impts. in.* J. C. Rombach and E. S. Restiaux, both of Melincroth, Neath, Glamorganshire. Eng. Pat. 12,024, May 15, 1897.

A MIXTURE of silicate of soda and asbestos, to form a cement by dilution with water, hydrochloric acid or other acid solution being used as a finishing wash or fixing agent.—V. C.

*Enamels or Cements, Process of Manufacture of Agglutinant.* B. J. B. Mills, London. From La Granitine Soc. Anonyme, Brussels. Eng. Pat. 15,336, Sept. 2, 1897.

A SOLUTION of silicate of soda is prepared having a density of  $1^{\circ}$  to  $2^{\circ}$  B. In this, chloride of magnesium is dissolved until the density reaches  $31^{\circ}$  to  $32^{\circ}$  B., then solution of sulphate of alumina is added to bring it up to  $32^{\circ}$  or  $33^{\circ}$  B. Finally, 55 per cent. of this liquid is mixed with 45 per cent. of calcined magnesite, forming a cement which "not only constitutes on the surface of ceramic products a most brilliant enamel, but also a powerful element of cohesion of foreign substances with which it is mixed."—V. C.

### X.—METALLURGY.

*Pyritic [Copper] Smelting, The Present Mode of.* H. Lang. Eng. and Mining J. 1897, 64, 37—38.

THE author comes to the following conclusions from the experience of the past two or three years.

Charges containing no more than one-third of their weight of sulphides can be smelted with as little as 2½ per cent. of coke and with a very high concentration. The slags made in pyritic smelting are as free from copper as those from ordinary matting, and those which have iron as almost the only base, are as free from copper, gold, and

silver as those containing lime or other base. The proportion of silica in the charge undergoing fusion, influences the concentration of pyritous ores to a great extent; the charge should contain as much silica as the furnace will stand for the heat necessary to fuse the material, and to induce the separation of the iron.—A. S.

*Gold Field, The Witwatersrand.* W. Y. Campbell. Eng. and Mining J. 1897, 64, 36.

THE country rock on the Witwatersrand is sandstone, quartzite and shale, and the seams, which dip south at angles of from  $15^{\circ}$ — $85^{\circ}$  from the horizon, vary from knife-edge selvages of black ferruginous sand, rich in gold, up to solid conglomerate seams of 10 and 15 ft. The strike of the seams is mainly east and west, and the average thickness is 3 in. on the east sections and 2—4 ft. on the Central Rand. The gold is practically all in the cement coating binding the pebbles, and is very seldom indeed found in the pebbles themselves or in the country rock. It nearly always occurs in very fine crystals and in mechanical combination with the cement or pyrites. Greenish diamonds are occasionally found in the mortar boxes. The line of oxidation is erratic, oxidised ore being sometimes found below unoxidised at some depth; the average depth is about 200 ft.—A. S.

*Cyanide Process [Gold], Prof. Christy on the; A Review.* W. Bettel. South African Min. J., May 8, 1897.

THIS is a criticism of Christy's paper on the Solution and Precipitation of the Cyanide of Gold (this Journal, 1897, 332). The Elsner equation is deemed insufficient, as an intermediary reaction producing  $\text{H}_2\text{O}_2$  or an equivalent substance, has been observed. Bodlander, of Clausthal, has represented the two stages thus:—

Bettel suggests the following:—

MacArthur asserted that gold will dissolve in cyanide solutions in the absence of free oxygen, and this is possible in the presence of basic ferric sulphate, which forms potassium ferrieyanide with the cyanide. Free cyanogen in the presence of cyanide solution is almost without action on metallic gold. The addition of the oxidising agents covered by Julian's patents has been proved of no value to the industry; and it is not true to assert that potassium chlorate, nitrate, and bichromate are of assistance in promoting the solution of gold, as they are too stable in alkaline solution to produce any such action. The author's experiments do not corroborate the statement that nearly all the oxidising agents are found to be effective. In regard to the solubility of gold sulphide in potassium cyanide, it is pointed out that the presence of silver in the gold would greatly impede or even prevent the action by the formation of a film of insoluble silver sulphide. The author has also shown previously that the presence of soluble sulphides in the fully aerated cyanide solution prevents the solution of metallic gold in it, unless oxidants or some substance such as lead hydroxide or carbonate be added. The regeneration of the cyanide solution proposed by Christy has already been patented by Adair in the Transvaal, but although successful in the laboratory, the process was found by Adair to be unsatisfactory on the large scale. The author considers that de Wilde's cuprous precipitation method has not the elements of a successful commercial process. In regard to the recovery of cyanide of potassium from strong solutions by zinc sulphate, Haut's method was anticipated by the author in 1893, but his patent has not been worked, owing to the distinct solubility of zinc cyanide in water, especially in the presence of hydrocyanic acid. The principle now adopted by Bettel consists in filtering the zinc-treated solution, after slight acidification, through a filter-bed of bright iron turnings or spongy iron, followed by filtration through magnesian limestone. The spongy iron removes all traces of gold from the solution. The statement that

gold cannot be precipitated by zinc shavings unless 0.1 to 0.2 per cent. of free cyanide be present, is disproved by daily practice on the Rand, where cyanide solutions containing only 0.04 per cent. of free KCy are reduced from 3 or 4 dwt. to as many grains per ton. Finally, the author ridicules as thoroughly unpractical and prohibitive as to cost, the proposal to acidify solutions containing calcium hydroxide.—W. G. M.

*Slimes, Zinc-Gold: Reduction of.* E. H. Johnson. Proc. Chem. and Metall. Soc. of S. Africa, for June 13, 1897, 12—15.

At the Princess Works, two 6-ft. clean-up vats have to be used in default of a filter press. One of these is fitted with a false bottom, having holes 1 in. square, covered with fine, closely-woven canvas. Below the partition, a 1½-in. pipe is passed through the side of the vat and connected to a small suction pump, which delivers the filtrate into a launder leading to the top of the precipitation boxes. The zinc-gold slimes are buckered into the filter vat, and are there filtered and washed with the aid of the pump. The filtration is slow, but must not be hurried for fear of bursting the canvas. When free from cyanide, the moist slimes are weighed in buckets as they are transferred to a large sheet-iron tray placed alongside the acid tank. The second vat is used for acid treatment, and is fitted with a detachable wooden stirring apparatus and a cover provided with a 3-in. pipe to lead fumes to the outside of the building. There is also a feed hopper, with sheet-iron valve below and cover above, to enable the charges of slime to be introduced without escape of fume. It is found best to use 1 lb. of strong sulphuric acid per pound of moist slime (equivalent to 1½ lb. of acid per pound of slime, dry). Sufficient water to form a 10 per cent. solution of the acid is first placed in the vat, the sulphuric acid is then mixed in, and finally the slimes are introduced with constant stirring, and the hopper and buckets are rinsed with a jet of water. The agitation is maintained for half an hour after action has apparently ceased. The vat is filled up with water, and the contents are allowed to settle. Working with dilute acid and without heating, perfect settlement results within an hour. The use of a steam jet renders the settlement more efficient. The deposit is then washed until neutral, by (usually four or five) successive washings, the water being well stirred each time by a paddle, and afterwards siphoned off. An average running sample of the washings assayed 13 grs. per ton. The slime is dried in large enamelled cast-iron dishes, the cakes are next broken up and heated to a higher temperature in thin layers on small sheet-iron trays; and, when cool, are ground, fluxed, and transferred to a crucible. The substance fuses quietly and with little fume, yielding 50—60 per cent. of the weight of slime as bullion. The average fineness of last year's bullion was about 820, and the slag, after panning out a few prills, contained 23 oz. per ton. 1 ton of such slag accompanied the production of 11,627 oz. of gold in the space of two years, which works out to 0.2 per cent. of the gold being locked up in the slags. From the following cost of a typical "clean-up," it is seen that the cost of reduction is 6.7d. per fine oz. :—

Dry weight of zinc-gold slimes.....	504 lb.
" after acid treatment .....	100 "
Yield of the gold.....	620 oz.
	£ s. d.
Cost of 672 lb. of acid @ 1½d. ....	12 12 10
" 60 lb. of borax @ 3½s. 6d. per cwt. ....	1 2 1
" 9 lb. of sodium carbonate @ 2½d. per lb. ....	0 1 10
" 3 lb. of flint spar @ 1d. per lb. ....	0 3 0
" 5 bags of coke @ 8s. 6d. per bag .....	2 2 6
" 1 No. 60 crucible .....	1 7 6
	<hr/>
	17 9 9

The cost of the acid may render this process slightly more expensive than the calcination method, but the immunity from unaccountable losses and the small amount of gold left in the slags more than compensates for this. —W. G. M.

*Nickel, The Fluidity of Melted.* J. Garnier. Comptes Rend. 1897, 124, 1447—1448.

At a meeting of the *Iron and Steel Institute* in 1891, the author propounded the view that the strengthening effect on steel, of small quantities of nickel is due to the extreme fluidity of the melted nickel, which enables it to penetrate into and fill the intermolecular interstices of the less fluid steel. He has obtained confirmation of this view from the accident of a piece of wood-charcoal becoming fixed near the lip of a crucible which was used for the reduction of nickel in the works of the Canadian Copper Co., Cleveland, Ohio. The vessels of the wood were found to be penetrated by the fluid nickel, which was obtained, after breaking up the charcoal, in the form of hair-like threads of extreme tenacity, very flexible and malleable.—J. T. D.

*Nickel Refining, Modern American.* T. Ulke. Zeits. für Elektrochem. 1897, [23], 521—524.

Two distinct methods are in use for the treatment of the matte produced by smelting Canadian nickel-copper ores in water jackets, and averaging 20—25 per cent. of copper, 18—23 per cent. of nickel, 25—35 per cent. of iron, and 20—30 per cent. of sulphur, according as it is desired (1) to obtain an alloy of copper and nickel, and (2) to recover the pure metals separately.

(1.) The matte is concentrated in a Bessemer plant, and the high-grade matte thus produced is roasted and reduced to the copper-nickel alloy. At the Sudbury Works, Ontario, of the Canadian Copper Company, 25 tons of cupola matte are treated and 15 tons of Bessemer matte produced in 24 hours. In the converters, the iron is almost entirely removed, the sulphur reduced to from 12—15 per cent., and the copper and nickel increased to about 43 per cent. and 40 per cent. respectively. The converter slags average 2 per cent. of copper and 3½ per cent. of nickel, and are returned to the cupolas for remelting. The exact point at which the blast should be increased, after the iron is removed and before the nickel is reduced in quantity to slag, can only be fixed by long experience.

The average composition of the Bessemer matte is 43.36 per cent. of copper, 39.96 per cent. of nickel, 0.3 per cent. of iron, 13.76 per cent. of sulphur, 7 oz. per ton of silver, 0.1—0.2 oz. per ton of gold, and 0.5 oz. per ton of platinum and palladium. The alloy produced contains about 51 per cent. of copper and 48 per cent. of nickel, and is used in the manufacture of German silver. The cost of Bessemerising the ordinary matte is stated to be 12—15 dols. per ton.

The author proposed in a previous article (Eng. and Mining J., Jan. 30, 1897) to refine Bessemer matte by dissolving it in dilute sulphuric acid, removing the copper by an electric current of low voltage, and then increasing the voltage so as to deposit the nickel free from copper, the precious metals being recovered from the slimes.

(2.) When it is desired to obtain nickel oxide or metallic nickel, the ordinary matte is smelted in a cupola with salt-cake and coke. In this way the salt-cake is reduced to sodium sulphide, which unites with the greater part of the iron and copper to form so-called "tops," and is tapped, together with the more nickeliferous "bottoms" into pots and allowed to cool. The tops are then separated by hand from the heavier bottoms. The weathered tops from the above process are subjected to what is termed top smelting, i.e., they are smelted, together with a little matte and sufficient coke, in a second cupola, so as to again produce tops and bottoms. In this process, the soda in the tops takes up some sulphur from the nickel in the matte and forms a sulphide, which unites with part of the iron and copper.

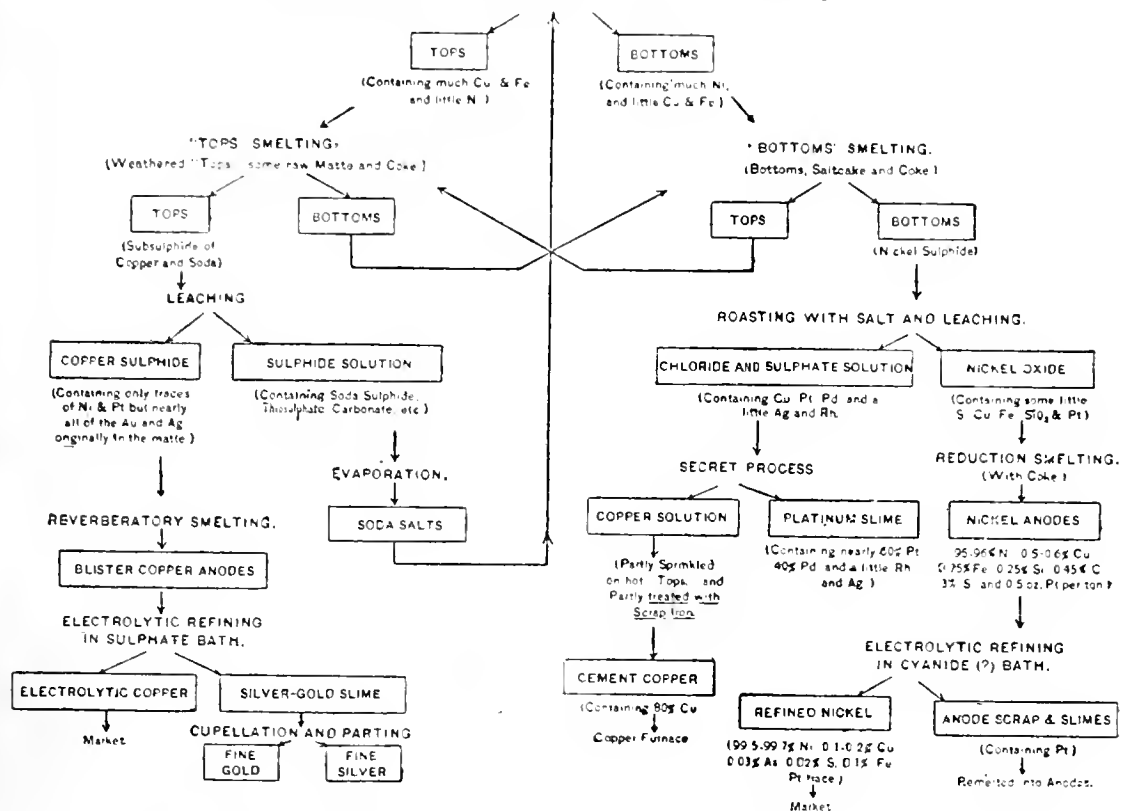

In bottom smelting, the bottoms from the first and second cupolas are mixed with salt-cake and coke in a third cupola, in which tops and final bottoms—composed of highly nickeliferous sulphide—are produced. The latter is roasted with salt in a reverberatory furnace and heated to a temperature at which as much nickel oxide as possible is formed, together with the chlorides and sulphates of copper and the precious metals. The roasted mass is then leached to separate the insoluble nickel oxide from the chloride and sulphate solution. The latter contains nearly all of the copper, silver, and palladium in the roasted bottoms.

Formerly, a cement copper was produced, containing 80 per cent. of copper with 60 oz. of platinum and 40 oz. of palladium per ton, by placing iron plates directly in the solution; but now the precious metals are precipitated out by a new method, and the residual solution is then sprinkled on hot tops or treated with scrap iron to produce cement copper. The leached nickel oxide is reduced with coke (at the Orford Works, near Constable's Hook, N.J.) to crude nickel, which is cast into anodes containing 95—96 per cent. of nickel, 0.2—0.6 per cent. of copper, 0.75 per cent. of iron, 0.25 per cent. of silicon, 0.45 per cent. of carbon, 3 per cent. of sulphur, and 0.5 oz. per ton of platinum. These anodes are electrolytically refined, a cyanide bath being probably employed, and refined nickel is finally obtained containing 99.5—99.7 per cent. of nickel, 0.1—0.2 per cent. of copper, 0.03 per cent. of arsenic, 0.02 per

cent. of sulphur, 0.1 per cent. of iron, and traces of platinum. The anode scrap is remelted into nickel anodes, and the slime treated to recover platinum.

The final tops, consisting chiefly of sub-sulphide of copper and soda, are leached, and the copper sulphide thus obtained as residue contains only traces of nickel and platinum, but nearly all of the gold and silver in the original matte. The solution carries down sodium sulphide, thiosulphate, and carbonate, &c., and the sodium salts obtained on evaporation are added to the smelting charge. The copper sulphide is reduced in reverberatory furnaces to metal and cast into anodes, and the latter are refined electrolytically by the ordinary multiple process in a sulphate bath. The gold-silver slime obtained is added to a lead charge and expelled down to *dore* bars. The *dore* is parted by sulphuric acid in the ordinary way, and cast into bars of fine silver and fine gold.

### Matte, Saltcake and Coke Tops and Bottoms Smelting.

DIAGRAMMATIC SCHEME OF THE ORFORD METHOD OF TREATING NICKEL COPPER MATTE.

—A. S.

*Nickel Steel: Physical Properties.* Engineer, Aug. 20, 1897, 187.

STEEL alloyed with nickel possesses a property of high importance, in that it does not develop cracks. It would appear that extensive employment of nickel steel will before long be made by boiler makers, for in high-pressure steam boilers a large saving in weight will ensue. For railway purposes, too, this alloy must have a bright future, as it should be specially adapted for locomotive details.

*Iron Ores, Notes on the Determination of Insoluble Phosphorus in.* C. T. Mixer and H. W. Du Bois. J. Franklin Inst. 1897, 144, 137.

See under XXIII., page 763.

### PATENTS.

*Sulphide Ores, Treatment of, for the Separation of Zinc*

*from the Lead and other Metals.* B. Mohr, Hampstead. Eng. Pat. 13,169, June 15, 1896.

The pulverised ore is fused with acid sodium or potassium sulphate, and the fused mass is dissolved in hot water, a small quantity of sulphuric acid being added when necessary. From the solution, zinc is deposited by electrolysis, and the liquid is then concentrated by evaporation until it is strong enough to be used for the fusion of a fresh batch of ore. The lead, silver, &c. of the insoluble residue is treated by known methods.—J. H. C.

*Sulphide Ores, An Improved Regenerative Process for the Treatment of.* E. T. Turner, Adelaide, Sth. Australia. Eng. Pat. 15,749, July 16, 1896.

SULPHIDE ores of zinc and lead containing small proportions of gold, silver, and other metals are placed, without being pulverised, in vats or digesters provided with gas-tight lids and perforated bottoms, arranged in series, and standing

over crucibles which can be heated. The said ores are sprayed from above with aqueous hydrochloric acid from a tank, whilst at the same time gaseous hydrochloric acid is supplied below the perforated bottom from a generator. The ore is gradually disintegrated, and a strong solution of metallic chlorides passes down into the crucibles together with the undissolved portions of ore and gangue. This solution is kept at the boiling point, raised by suitable means, and made to pass through a new portion of ore, until a neutral saturated solution of chlorides is obtained.

The disintegration of the ore is accompanied by the production of sulphuretted hydrogen, which is also made to circulate through the ore under treatment until it finally passes, practically free from hydrochloric acid, into a purifying chamber, and thence to a gasholder, from which it is drawn off to be used as fuel.

As each crucible becomes filled with particles of undecomposed ore and gangue, and with the deposited chlorides of silver, lead, zinc, &c., its vat or digester is disconnected, and it is withdrawn from the series. The temperature of the mass in the crucible is now raised to about 300° C., when a fused mass of chlorides, &c. is produced, which is subsequently lixiviated, and the metals precipitated from the solution.—J. H. C.

*Metals and Alloys, An Improved Method for the Production of.* C. Vautin, London. Eng. Pat. 16,685, July 28, 1896.

The compounds to be reduced, are finely pulverised and mixed with finely powdered aluminium, or a mixture of aluminium and magnesium; a small portion of a mixture similar to the first, but coming more easily into reaction, is placed on the top, and this is heated so as to start its reaction, which then spreads to the main mass, being maintained by the heat developed by the initial reaction.

For example, to obtain the metal chromium, equivalent parts of oxide of chromium and aluminium are placed in a crucible which has been previously lined with magnesia. Upon the mixture is placed a little cartridge composed of peroxide of barium and aluminium intimately mixed and compressed. To this cartridge a thin piece of magnesium is attached. When this is ignited, it ignites the cartridge and reduces the peroxide of barium, and by this reaction enough heat is produced to ignite the whole mass, similarly reducing the oxide of chromium to metal.—J. H. C.

*Solutions of Copper, An Improved Process for the Preparation and Purification of.* J. C. Graham, London. Eng. Pat. 17,127, Aug. 1, 1896.

CRUDE cuprous chloride solutions, containing iron and other impurities, such as the liquors obtained by "lixivating ores," are treated with lime or an alkali, in such proportion as to precipitate ferric hydroxide, leaving the copper salt undecomposed. The copper is then thrown down from the cleared liquor as hydrated oxide by a further addition of the lime or alkali. The precipitate, after collection, is churned with water through a centrifugal pump, and after settling, the process is repeated to complete the washing. The cuprous hydroxide may then be dissolved by sulphuric acid, and copper electro-deposited from the solution. "If the original impure solution was a sulphate and not a chloride, then the second addition of a base may be dispensed with."—E. S.

*Gold and Silver, Impts. in the Recovery of, from their Solutions.* W. H. Gopner and H. L. Diehl, Hamburg. Eng. Pat. 17,193, Aug. 7, 1896.

GOLD and silver are precipitated from their cyanide solutions by adding cuprous cyanide or silver cyanide or their mixture, and then adding an acid to effect precipitation. The precipitate is dissolved by a fresh quantity of the cyanide solution obtained by leaching, and acid again added so as to effect successive precipitations from the said solution.—J. H. C.

*Zinc Ores or Ore Residues; Impts. in and relating to the Treatment of, in the Production of Zinc, Chlorine, Sodium Sulphate, and other Products.* H. Breuer. Eng. Pat. 17,839, Aug. 12, 1896.

SULPHIDE ores are roasted with sodium chloride and then leached, so as to dissolve out the sulphates thus formed,

Calcium chloride is then added so as to convert them into chlorides and to regenerate the sodium chloride. The gypsum thus formed is separated, as also any iron present, preferably by means of calcium carbonate, as ferric hydrate. The liquid is then evaporated, and the excess of sodium chloride (and of sodium sulphate) crystallised out. Finally, the solution is electrolysed so as to yield zinc and chlorine.—J. H. C.

*Tin Oxide, Treatment of, in the Form of Powder, Sludge, or Paste, for the Smelting thereof.* E. E. von der Linde, Crefeld. Eng. Pat. 11,602, May 10, 1897.

THE tin oxide, &c. is mixed with a small proportion of caustic alkali or alkaline carbonates, tin slag is added, and then lime or carbonate of lime. Water is added, and the mixture is ground fine so as to produce a tough, pasty mass, which is moulded into briquettes and dried. The following proportions are recommended:—100 parts of tin oxide, 10 parts of slag, 8 parts of lime or carbonate of lime, and 2.5 parts of caustic alkalis or alkaline carbonates.

—J. H. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A).—ELECTRO-CHEMISTRY.

*The Copper Voltameter: Its Advantages and Disadvantages.* F. Feerster. Zeits. f. Elektrochem. 1897, 3, 479—482 and 493—497.

THE copper voltameter is largely used by chemists, mainly because it is so very handy. The results obtained from it, especially with small currents, are known to be rather uncertain. Investigations made by the author (with O. Seidel) on the electrolysis of copper sulphate solutions show how and why the copper voltameter can be used for accurate work. They show that in the electrolysis of copper sulphate solutions between copper electrodes, the simple transference of copper from the anode to the cathode is not always the only process which goes on. Copper forms two sets of salts, and, during the reactions which go on, cuprous salts may be formed. Hitherto the existence of a cuprous sulphate has not been admitted. The authors have not succeeded in obtaining it in the solid form, but they have no doubt that it can exist in solutions of cupric sulphate, even if only in a dilute state. It is formed at the cathode, especially when the current-density is less than 0.01 ampère per square decimetre. The tendency of cupric ions to become transformed into cuprous ions increases with temperature, so that at 100°, even with a current-density of 0.03 ampère per square decimetre, in concentrated copper sulphate solution the current forms almost exclusively, cuprous ions at the cathode.

As was long ago shown by Jacobi, these ions can even be formed without any current, by the action of copper on cupric ions (e.g., in the case of cupric chloride); thus:—

In neutral solutions the cuprous sulphate formed, as soon as its concentration reaches a certain value, suffers hydrolysis; thus:—

Cuprous oxide is deposited on the cathode (often in brilliant crystals), and the solution becomes acid. If the solution is acid enough, the hydrolysis does not take place, and more cuprous ions remain than in neutral solution. But as soon as the proportion of these to cupric ions reaches a certain value, they interchange, with deposition of metallic copper—

This should be regarded as "secondary" copper. It forms separate crystals, not like the usual smooth deposit from acid solutions.

One of the most important points in the use of the copper voltameter is the composition of the electrolyte.

This is generally concentrated, and rightly so: a weak solution is apt to give a pulverulent deposit of copper on the cathode. With regard to the presence and effects of cuprous ions, it must be pointed out that the voltameter is used in presence of air, and on exposure to air, the cuprous ions are oxidised to cupric ions. If the solution is acid, copper sulphate is formed—

If it is neutral, basic copper sulphate is formed—

In his second paper the author discusses the errors of the copper voltameter, and how they can best be avoided. It has one unavoidable defect, *viz.*, the low electro-chemical equivalent of copper. But when the composition of the electrolyte and the density of the current are suitably chosen, the instrument is a more accurate one than is usually supposed. It is handier and simpler than the silver or mercury voltameter, and will remain the favourite instrument for technical work. For general use an electrolyte containing 125 grms. of crystallised copper sulphate and 50 grms. of pure sulphuric acid (sp. gr. 1.84) per litre is recommended. When small currents and low current-densities have to be used, it is well to add alcohol, as recommended by Oettel, who uses an electrolyte made up of a litre of water, 150 grms. of copper sulphate, 50 grms. of sulphuric acid, and 50 grms. of alcohol. By proper adjustment of the current-density, currents from 0.01 ampère down to 0.005 ampère can be measured with sufficient accuracy. The cathodes are made of copper wires 1 mm. thick, flattened out at the ends. But for very small currents the author prefers to use a closed voltameter in which the electrolyte and electrodes are kept from contact with the air. In this case no alcohol is added to the electrolyte, but hydrogen is allowed to bubble through it before and during the electrolysis. In order to prevent undue variations of current-density, a number of cathodes of varying size should be kept ready, the smallest being made by flattening out the ends of platinum wires 0.5 mm. thick. When large currents are measured, it is well not to allow the current-density to exceed 2 amperes per square decimetre. Above this the copper is apt to be deposited on the cathode in a loose powdery form.

—D. E. J.

*Electrolysis of Mixtures.* A. Schrader. Zeits. f. Elektrochem. 1897, 3, 498—505.

WHEN a mixture of aqueous solutions of copper sulphate and sulphuric acid is electrolysed, hydrogen and copper are generally set free at the cathode, but sometimes copper alone. According to Hittorf's views as to the nature of electrolytic processes, the current traverses the two dissolved electrolytes in proportion to their respective conducting powers in the mixture. Primarily, hydrogen and copper are set free at the cathode, but by a secondary reaction, a part of the primary hydrogen may deposit more copper. The author has endeavoured to determine this part under various conditions. The investigation naturally falls under two heads:—(A) The determination of the ratio  $x$ , in which the current divides between the two electrolytes. Upon this can be based (B) the actual experiments upon the question above stated. (A) has an interest apart from (B), and from the purely theoretical point of view is perhaps the more important question. The most important experimental results are the following:—(1) By translation experiments the author has determined the ratio in which the current divides between the components of two mixtures, *viz.*, (a) aqueous solutions of potassium chloride and potassium iodide, (b) aqueous solutions of sulphuric acid and copper sulphate. The results obtained are used to calculate the change of the degree of dissociation of the components produced by mixing. (2.) The translation-number of acetic acid approximates with increasing dilution to the theoretical value  $N = 0.119$ ; but even with a dilution of  $V = 4$  this value is not quite attained. ( $V$  is the number of litres which contain a gramme-molecule of  $\text{CH}_3\text{COOH}$ . The "trans-

lation-numbers" are those of the anions of the components in accordance with Hittorf's definition; so that if these be  $N_1$  and  $N_2$  the translation-numbers of the cations are  $1 - N_1$  and  $1 - N_2$ .) (3.) From the results of (1) the author determines what fraction of the primary hydrogen goes to deposit copper (in the case of mixed solutions of  $\text{CuSO}_4$  and  $\text{H}_2\text{SO}_4$ ). Within the limits of experimental error the fraction  $\sigma$  can be expressed by the formula—

$$\sigma = \frac{A}{C + B}$$

when  $C$  is the current-density and  $A$  and  $B$  are constants. For sufficiently dilute solutions,  $B$  appears to be equal to  $A$ , so that the formula takes the simpler form—

$$\sigma = \frac{A}{C + A}$$

—D. E. J.

*Luckow's Method for Electrolytic Production of Insoluble Oxides and Salts from Metallic Anodes.* Zeits. f. Elektrochem. 1897, 3, 482—485.

WITH regard to the Luckow patents, it has long been known that lead peroxide is formed on lead anodes in certain solutions, and white lead, chrome yellow, &c., in other solutions. But although these problems have apparently been solved, everyone who has tried to apply them technically knows how very difficult it is to carry out the methods in practice. Hitherto there has been no electrolytic method which would produce upon the anodes products of sufficiently approximate purity for commercial purposes. Even lead peroxide thus prepared contains 20 per cent. or more of impurity. Tibbitts' process apparently resembles Luckow's, but owing to the high concentration of the electrolyte or some other cause, the white lead produced by it is neither pure nor cheap enough. In fact, we have not, until now, had any technically useful process for the direct electrolytic production of lead peroxide, white lead, chrome yellow, zinc white, or similar products.

The essential point of Luckow's discovery is in the establishment of the following fact:—When the electrolyte is diluted so far that its electrolytic dissociation reaches as high a degree as will still admit of good conductivity (what may be called its practical maximum), the desired products are obtained in a state of purity hitherto unattained. In addition to the actual electrolyte, there is generally present a second salt. The ionisation of the first is of primary importance; it brings the anode-metal into solution. The rôle of the second is to convert the dissolved metal into the desired compound. Both should be highly diluted. For the preparation of insoluble salts, a solution is used in which the primarily active electrolyte (which dissolves the anode) is to the secondary electrolyte (which causes the precipitation) in the proportion of 80 to 20. The end-product does not adhere firmly to the anode; indeed, it is formed at a slight distance from it. It is found at the bottom of the bath in the form of a finely divided but dense powder of great covering power. When oxides are required, a strongly diluted solution is used of a salt, the oxide of which does not form with the anode any soluble salt; to this is added quite a small quantity (0.5 per cent. of the solid constituents) of a salt the anion of which forms with the anode-metal a soluble compound. It is convenient to use as cathodes, plates of the same metal which serves as the anode. The solution is generally kept neutral; in many cases this is best attained by the addition of a salt, which easily suffers hydrolytic dissociation.

*Preparation of Lead Peroxide.*—The electrolyte is a 1.5 per cent. aqueous solution of a mixture of 99.5 parts of sodium sulphate with 0.5 part of sodium chlorate by weight. It is very slightly acidified with sulphuric acid. E.M.F., 2.8 volts; current-density, 0.2 ampère per sq. dem.

*Preparation of White Lead.*—The electrolyte is a 1.5 per cent. aqueous solution of a mixture of 80 parts of sodium chlorate with 20 parts of sodium carbonate, and is kept slightly alkaline. E.M.F., 2 volts; current-density, 0.5 ampère per sq. dem.

*Preparation of Neutral Lead Chromate.*—The electrolyte is a 1.5 per cent. aqueous solution of a mixture of 80 parts of sodium chlorate with 20 parts of sodium chromate, and is

kept neutral. E.M.F., 1.8 volts; current-density, 0.5 ampère per sq. dem.

**Preparation of Acid Lead Chromate.**—The electrolyte has the same composition as the preceding, but is kept acid with chromic acid. E.M.F., 1.5 volts; current-density, 0.5 ampère per sq. dem. In all the above, the anode is of soft lead and the cathode of hard lead.

**Preparation of Copper Oxide.**—The electrolyte is a 2 per cent. solution of a mixture of 95 parts of sodium borate and 5 of sodium chloride, and is slightly alkaline. The electrodes (here and in the next two) consist of copper. E.M.F., 2 volts; current-density, 0.5 ampère per sq. dem. (Same conditions for the next two.)

**Preparation of Basic Copper Carbonate.**—The electrolyte is a 1.2 per cent. solution of a mixture of 80 parts of sodium chloride and 20 of sodium carbonate, and is slightly alkaline.

**Preparation of Basic Copper Phosphate.**—The electrolyte is a 1.5 per cent. solution of a mixture of 80 parts of sodium chloride and 20 of sodium phosphate, and is slightly alkaline.

There is no doubt that the oxide, zinc carbonate, Prussian blue, and other substances which are insoluble or nearly so, can be prepared by the same process. The manufacture of white lead has already been tested in all the technical details, and capitalists in Cologne and the neighbourhood have formed a company to exploit the process.—D. E. J.

**Potassium Bromide and Fluoride. Electrolysis of.** H. Pauli. Zeits. f. Elektrochem. 1897, 3, 474—478.

AFTER the electrolysis the amount of hypobromite was determined by means of potassium arsenite in alkaline solution ( $2\text{KBrO} + \text{As}_2\text{O}_3 = \text{As}_2\text{O}_5 + 2\text{KBr}$ ), and the total bromine in both salts (hypobromite and bromate) by means of potassium iodide and dilute hydrochloric acid. The iodine was titrated with sodium thiosulphate. From the two results the bromine in the form of potassium bromate can be calculated. Before commencing the electrolytic work, experiments were made on the formation of hypobromite and bromate of potassium chemically. To equal quantities of 10 per cent. potash solution, bromine was added in quantities proportional to 1:2:4:8:32:48. The results of the titration are as follows:—

Bromine in

	Hypobromite.	Bromate.
1	0.0110	0.0052
2	0.2168	0.0063
3	0.2752	0.0120
4	3.5528	0.0532
5	0.0755	0.2517
6	Traces	0.8235

Thus, when potash is in excess, the chief product is hypobromite. As more bromine is added, it acts upon the hypobromite first produced and forms bromate; and when a large excess of bromine is present the hypobromite almost disappears. By heating the solution, hypobromite is partially converted into bromate; the change takes place more rapidly in dilute than in concentrated solutions.

The results obtained in electrolyzing solutions of potassium bromide are in general similar to those obtained by Oettel in his investigation on the formation of hypochlorite and chlorate by electrolyzing solutions of potassium chloride. In two respects they differ. It is impossible to obtain equally good yields, because the bromate formed (unlike the chlorate) is reducible in alkaline solution. Now it is possible to conduct the electrolysis under conditions such as to produce (as in the electrolysis of potassium chloride in alkaline solution) only bromate (with a negligible amount of hypobromite). Details are given of electrolyses of 10 and 20 per cent. solutions of potassium bromide, neutral and alkaline, hot and cold.

Attempts were also made to produce hypofluorides and fluorates from fluorides. Neutral 20 per cent. potassium fluoride solution was electrolysed under various conditions of temperature and current-density; a strong smell of ozone

was noticeable, but no other result was obtained. Caustic potash was then added in gradually increasing quantities to the fluoride; but again the experiments gave negative results.—D. E. J.

**Nitrobenzene, Electrolytic Reduction of.** W. Löb. Zeits. f. Elektrochem. 1897, 3, 471—474.

GATTERMANN succeeded in reducing nitro-compounds electrolytically in sulphuric acid to amidophenols, phenyl-hydroxylamine being produced as an intermediate product. Probably the author's electro-syntheses of chlorinated and brominated aniline by reduction of nitrobenzene in hydrochloric (or hydrobromic) acid solution took place in analogous fashion. The whole course of the reaction indicates that phenylchloramine (or phenylbromamine) was present as an intermediate product, although it could not be isolated. The author has now endeavoured to carry out electrolytically a general reaction of the following nature:—

Details of three series of experiments are given, in which the nitrobenzene in various solvents was electrolysed in a beaker with a porous cell. The cathode was of platinum or lead. The anode was of platinum or carbon, and the liquid in its neighbourhood was dilute sulphuric acid. It is not advisable to use lead as the positive electrode, because it dissolves in the solutions. I. **Reduction in Formic Acid Solution.**—The reaction expected was analogous to that which occurs when halogen acids are used:—

Thus amido-benzoic acid would be obtained direct from nitrobenzene. The expectation was not fulfilled. The chief product of the reaction is hydrazobenzene, which, in the presence of the acid, is transformed into benzidine formate. II. **Reduction of Solutions of Nitrobenzene in Acetic and Oxalic Acid.**—Here again the chief product of the reaction is benzidine (acetate or oxalate). III. **Reduction in Ammoniacal Solution.**—Nitrobenzene dissolved in alcoholic ammonia, or a mixture of aqueous ammonia and alcohol, has an exceedingly low conductivity. This, however, can be increased (without affecting the reaction) by adding ammonium chloride. Here again, hydrazobenzene was formed and precipitated; on passing steam through the filtered liquid, azobenzene was obtained.—D. E. J.

**Nitric Acid, Quantitative Determination of, by Electrolysis.** K. Ulsch. Zeits. für Elektrochem. 1897, 3, 546.

See under XXIII., page 762.

## PATENTS.

**Electrical Accumulators** [Electrodes, "Forming," &c.], Impts. in. X. M. Roux, Paris. Eng. Pat. 12,696, June 9, 1896.

"(1) THE combination with the positive plates of a coating of unoxidisable metal or non-metallic substance, such as carbon, silica, or the like, by means of electrolysis . . . (2) A plate consisting of a support of glass, porcelain, or other inert material, in combination with windings of lead wire, strip, or tube, perforated or not . . . (3) Pellets or fillings of minium and litharge, combined with asbestos or other absorbent and inert material . . . (4) An electrolyte, consisting of oxalic acid, with or without sulphuric acid, when used as the 'formation' electrolyte, or with sulphate of manganese . . . (5) . . . sheaths of non-conducting absorbent asbestos for the purpose of insulating the plates from each other and to enable the plates to be packed closely together. . . ."—J. C. R.

**Electric Battery** [Carbon with Fused Metallic Oxide], An Improved. H. F. Kirkpatrick-Pieard, London. Eng. Pat. 15,223, July 9, 1896.

(1) THE production of electricity by the consumption of carbon in an electrolyte composed of a molten metallic

oxide which is decomposed more readily by the carbon than by the metal vessel ("litharge melted in a copper crucible") in which it is held and which forms the other element . . . (2) By the consumption of carbon in an electrolyte composed of a molten metallic oxide . . . (3) By the consumption of carbon in an electrolyte such as litharge or other suitable oxide contained in a copper vessel, whereby the metallic lead is deposited on the vessel and the oxygen of the oxide converted into carbonic acid . . . (4) In the production of electricity by the consumption of carbon in an electrolyte such as litharge, the regeneration of litharge or the oxide by an air or oxygen blast. (5) The employment, as the electrolyte in a battery such as described, of litharge or other oxide diluted with oxide of sodium, or with caustic soda or potash, or with soda and silica, forming a double silicate, for the purpose described, "to dilute the litharge," to reduce "the strong local action (of a purely chemical nature) and the consequent production of heat," and "to reduce the melting point of the bath." (6) "The employment, as the electrolyte in a battery such as described, of litharge or other oxide diluted with oxide of sodium, or with caustic soda or potash, forming, in the case of lead, alkaline plumbates, or with other metallic oxides forming similar alkaline and metallic compounds; or with soda and silica forming double alkaline silicates."—J. C. R.

*Phosphorus, An Improved Process of Manufacturing.* [Electric Furnace.] L. L. Billaudot, Paris, France. Eng. Pat. 15,977, July 18, 1896.

THE process consists in heating metallic phosphates with carbon in an electric furnace so as to obtain the corresponding metallic phosphides, and subsequently heating these phosphides, or phosphides obtained by any other means, with carbon in an electric furnace, with the production of phosphorus and the carbide of the metal. The two stages may be combined in one operation, as in the case of the production of calcium carbide and phosphorus from tricalcium phosphate.—G. H. R.

*Primary Batteries [Leclanché, Air-tight], Impts. in and relating to.* R. M. J. Heurtey, Paris, and P. Germain, Auxerre, France. Eng. Pat. 16,597, July 27, 1896.

RELATES to the construction of an air-tight battery of Leclanché type, with double chloride of ammonium and magnesium for electrolyte, and cellulose (cocoa-nut, rush) between or around electrodes.—J. C. R.

*Electrical Accumulators [Filling-Grids], Impts. in.* A. Conder, London, and P. Michélot, Paris. Eng. Pat. 18,951, Aug. 27, 1896.

A GRID, formed by burning or riveting together two separate grids for holding active material, which, as a paste, is made up of sulphuric acid, water, glycerin, and magnesium sulphate, in combination with oxides of lead. The acid (1 in 10) is first added to the glycerin (3 parts by vol.), and allowed to cool.—J. C. R.

*Accumulators, Zinc [Amalgamated], Negative Electrode for.* S. Pitt, Sutton, Surrey. From L. Bonnel and Société Bisson, Berges and Co., Paris. Eng. Pat. 15,913, June 21, 1897.

"A NEGATIVE electrode for accumulators constituted by a combination of a supporting conducting strip [copper, &c.], and a trough or basin [ebonite, porcelain, celluloid] containing mercury, in which the said strip rests [vertically]; this arrangement allowing, whilst charging, of continuous amalgamation by the mercury, which creeps along the strip of the electrolysed zinc deposited upon it, and, whilst charging, of the recuperation and preservation of the mercury, which may thus be used again and again indefinitely."—J. C. R.

*Utilising the Residual Products [Caustic Alkali Solution of Zinc] obtained in the working of certain kinds of Voltaic Batteries, Impts. in.* W. Walker, jr., and F. R. Wilkins, Birmingham, Jabez Jones and Joseph Jones, Smethwick. Eng. Pat. 19,308, Sept. 1, 1896.

ZINC is precipitated as sulphide from spent caustic alkali battery solutions, either by boiling with flour sulphur, or by

addition of an alkali sulphide, or by hydrogen sulphide. The washed and dried zinc sulphide may be fitted for use as a white pigment by heating with 3 per cent. of sulphur to dull redness for half an hour, and then throwing into water; the latter is then removed and the product dried. To regenerate the alkali after removal of zinc, the thio-sulphate that has been formed in the initial process, is oxidised, either by hydrogen peroxide, or barium peroxide, or by electrical action; the liquid is then diluted to a density of 1.05, and is boiled with lime, with addition, at the end, of barium hydroxide solution. After clearing, the solution is concentrated for re-use.—E. S.

*Rubies, Impts. in the Manufacture of Artificial.* [Electric Furnace.] W. P. Thompson, London. From the Firm of Gin and Leleux, Paris, France. Eng. Pat. 19,962, Sept. 9, 1896.

A MIXTURE of 95 per cent. of alumina and 3 per cent. of sesquioxide of chromium are melted and volatilised in an electric furnace, heated by an alternating current, and the gaseous products are led through a tube to a condensing chamber heated to 1,500° C. To facilitate the formation of large crystals, a mixture of moist air and hydrochloric acid is forced under pressure into the tube; or, whilst moist air is passed through the tube, small quantities of fluoride of aluminium or eryolite are cast on to the hearth of the furnace from time to time, thus causing the formation of hydrofluoric acid. The fine crystalline deposit formed in the condensing chamber and tube are removed periodically, and can be utilised in place of emery.—G. H. R.

*Electrolyser or Electrolytic Apparatus, An Improved.* [Mercury Cathode.] J. G. A. Rhodin, Eccles. Eng. Pat. 21,509, Sept. 29, 1896.

THE electrolyser consists of two concentric cylindrical vessels, the inner one of which contains the electrolyte, and is capable of rotation, and in its bottom is formed a series of hollow tubes or projections containing the carbon or other suitable anodes. The bottom of the outer vessel is provided with radial ribs or projections to retain the layer of mercury which covers it, and above the mercury is water or other liquid which will absorb the cations from the amalgam formed. The electrolyte is preferably a metallic salt, the cation of which is soluble in mercury, and when the inner vessel is rotated, the amalgam formed in the tubes is brought into contact with the body of the mercury and with the supernatant liquid. If it be desired to apply heat during the operation of electrolysis, the outer vessel is preferably formed of iron, and the inner vessel is constructed as a still and hermetically sealed.—G. H. R.

*Galvanic Elements, Primary and Secondary [Deposited Zinc Electrodes]; Impts. in and connected with.* H. Leitner, Berlin. Eng. Pat. 24,473, Nov. 2, 1896.

"AN electrode for primary or secondary galvanic element consisting in (1) electrolytically depositing a layer of zinc upon a suitable base or core by the aid of a lead peroxide [anode] plate; (2) amalgamating the said layer; and (3) depositing electrolytically an outer layer of zinc . . . upon the said amalgamated layer, the said outer layer being adapted to serve as the active material of a primary or secondary battery . . ." The zinc is deposited from a bath made up of zinc sulphate, sulphuric acid, and alum (preferably ammonia alum).—J. C. R.

*Secondary or Storage Batteries or Accumulators [Forming, Filling, Terra-Cotta Supports], Impts. in, and in the Manufacture of the same.* J. Y. Johnson, London. From J. P. Clare and G. L. Hatch, Quincy, Mass., U.S.A., and J. H. Taylor, Chelsea, Mass., U.S.A. Eng. Pat. 15,510, June 29, 1897.

1. "THE process of preparing a secondary battery element . . . consisting in autogenously forming active material from the metal of an electrode by electrolytic action, then loosely confining against the coated face of the plate thus produced, granular or pulverulent [dry powder preferred] active material, or material to become active, and continuing the electrolytic action so as to effect the union of this mass with the autogenously produced material on the plate . . .

Other claims relate to the mechanical construction of receptacles and electrodes, in which plates of porous earthenware (terracotta) are requisitioned for supports.—J. C. R.

*Peat Charcoal, Process for Producing, by Means of an Electric Current.* C. A. Jensen, London. From P. Jøben, Brvik, Norway. Eng. Pat. 15,513, June 29, 1897.

The process consists in compressing the peat into thin layers, and inserting it as a resistance in an electrical circuit so as to carbonise it.—G. H. R.

### PATENTS.

*Tubes, Impts. in Apparatus for Manufacturing, by Electrolytic Deposition.* [Reciprocating Mandrel.] A. S. Elmore, Leeds. From J. O. S. Elmore, Kappitlala, India. Eng. Pat. 7222, April 2, 1896.

The depositing vat is of U-section, and divided along its length into compartments, which contain alternately anode shells of the crude metal to be deposited, which surround, or nearly surround a mandrel, and fixed rubber making electrical contact with this mandrel, which is mounted in the tank and rotated, and is also given a reciprocating motion between burnishers, which are also supported in the same compartments. The mandrel is lengthened at each end by pieces of non-conducting material, passing through stuffing boxes at the ends of the tank. Two or more tanks and mandrels may be arranged in line, the latter being connected by non-conducting material, and the anode shells of each tank being electrically connected to the rubbers on the cathode mandrel of the next tank. The electrolyte is circulated through the tank in large volume by means of a suitable pump.—G. H. R.

*Tin or Antimony Ores, Impts. in or relating to the Treatment of, and the Separation of the Gold and Silver contained therein.* C. F. Claus, Chiswick. Eng. Pat. 13,641, June 20, 1896.

The crude metal obtained by smelting, is immersed in an electrolyte (such as sulphide of sodium of sp. gr. 1.065, or in some cases sodium and potassium hydrate, and heated to 90° C.) and employed as the anode for an electric current of about 10 amperes per square foot of cathode: any suitable material may be employed for the cathode. The crude metal is gradually dissolved and pure tin is deposited upon the cathode. The gold, silver, lead, copper, zinc, iron, antimony, &c. remain insoluble in the anode-mud, some as sulphides and others in the metallic form.

For the separation of antimony, the anode-mud or the ore is smelted with sodium sulphate, carbon and sulphur being added when required. The slag from this smelting contains the antimony in a soluble state; it is dissolved in water and the antimony is deposited by means of an electric current or by known methods, as sulphides.

In some cases, instead of smelting as above, the ore may be fused with proper proportions of sulphur and soda, or sodium sulphate and carbon; or boiled with a solution of polysulphide of sodium, adding an ammonium salt, so as to obtain a proper solution for electrolysis.—J. H. C.

*Zinc or other Metals, Impts. in Means or Apparatus for Effecting the Electro-Deposition of, upon Tubes or other Circular or Analogous Objects.* [Internal Anodes.] The Cowper-Coles Galvanising Syndicate, Limited, and S. O. Cowper-Coles, London. Eng. Pat. 17,608, Aug. 8, 1896.

The apparatus for the electro-deposition of zinc or other metals on tubes or other circular or hollow objects consists of a vat approximating in shape to the article to be coated,

in which are suitable bearings carrying supports capable of rotation, and which hold the tube at each end. These supports or holders consist of three portions, and have V-shaped converging projections with their edges outward to bear on the object to be coated. A hollow perforated anode passes through, and is attached to the central portion of one holder, and on the other end of it slides a holder formed of a vulcanite outer portion and an inner metallic portion consisting of a ring carrying V-shaped projections, and means are provided for rotating the object to be plated. The interior of the containing vessel is lined with the metal to be deposited, and forms an external anode, and the electrolyte is circulated through the internal anode and the tank under pressure.—G. H. R.

*Electrolytic Apparatus, Impts. in.* [Tapered Cathodes.] W. L. Wise, London. From The Aluminium Industrie Aktien-Gesellschaft, Neuhausen, Switzerland. Eng. Pat. 21,027, Sept. 22, 1896.

IN the reduction of sodium or of other light metals by electrolysis, the oxidation of the reduced metal is obviated by employing tapered or rounded cathodes, which dip only a portion of their surface into the electrolyte, while the anodes have a protective casing fixed by asbestos, which allows of the escape of the oxygen. The electrodes are arranged alternately, and suspended over the vessel containing the fused electrolyte from two beams, the anodes being carried by one, and the cathodes by the other, so that they may be raised or lowered independently as required. The deposited metal is removed by scraping from time to time, and placed in a collecting vessel, cylindrical in its upper part and conical in the lower, which is provided with a central hole, closed with a pin, so that the electrolyte can be allowed to escape while retaining the metal. This vessel is supported in the bath by its handle.—G. H. R.

### XII.—FATS, OILS, AND SOAP.

*"Saponification" of Unsaturated Alcohols and Neutral Bodies.* R. Henriques. Zeits. angew. Chem. 1897, 398.

THE author has already stated that on treatment with alcoholic alkali, either hot or cold, at ordinary or increased pressures, wool-fat suffers greater change in constitution than corresponds to the mere decomposition of its esters; and he has suggested that the phenomenon is due to the action of the alkali on the unsaturated alcohols. This view Herbig objects to, on the ground of the impossibility of such reaction. Henriques has therefore endeavoured to solve the problem by direct experiment; but as of the unsaturated alcohols and neutral bodies in wool fat only cholesterolin has yet been isolated, he has studied the properties of some alcohols derived from other sources. The results of the investigation show that all such compounds are more or less attacked by alkalis, that among the products of the action some acid is to be found, and that they consequently possess a "saponification number."

By heating for two hours at 100° C. in a sealed tube with 10 per cent. alcoholic potash, linalool gave figures corresponding to the presence of 1.16 to 1.86 per cent. of ester, or to the saponification number 4.2 to 6.8. In the cold its saponification number in 24 hours was 4.2; in seven days, 3.9. Similarly, with geraniol, the values were 2.8 and 3.92. In both cases the acids were extracted, and found to be yellow oily bodies insoluble in water. Cinnamic alcohol yielded saponification numbers of 9.35 and 12.04 after being mixed with normal alkali for 48 hours in the cold, while the residual alcohol, on fresh treatment, gave 3.36; boiled for 1½ hour with the same reagent, its number was 14.44. Safrol, anethol, and eugenol were also examined, but the strong red colour produced by the last prevented the titration from being carried out. The figures in the former cases were:—

	1 Hour Warm.	24 Hours Cold.
Safrol.....	9.7—14.8	5.52
Anethol.....	6.05	4.48—5.08

The exact mechanism of this decomposition is the subject of a research which is not yet concluded; but in the meantime it has been proved that cinnamic alcohol is totally changed in structure by cold normal alkali in 24 hours. When the product is distilled from the acids, the thermometer rises constantly to 260° without remaining at any one point, and the residue is thick and oily, and contains benzoic acid. The distillate smells strongly of bitter almonds, and, on treatment with bisulphite and sulphuric acid, yields benzaldehyde. Another ketone of the empirical formula  $C_{10}H_{10}O_2$ , giving a hydrazone  $C_{10}H_{12}N_2$  (m.p. 120°) is also present, and probably consists of  $C_6H_5.CO.CH_2.CH_2.OH$ . Under similar conditions, anisaldehyde and anisic acid were obtained from anethol. Lanolin also yields an aldehyde, but it has not yet been produced in sufficient quantities for identification.—F. H. L.

### PATENTS.

*Lubricants, Impts. in.* F. W. Kleyer, Cologne, Germany. Eng. Pat. 17,118, Aug. 1, 1896.

HEAVY mineral oils are mixed with oleic acid and alkali or alkalis, preferably ammonia. This mixture readily forms an emulsion with water.—C. A. M.

*Soap, Impts. in the Manufacture of.* E. S. Wilson, Strood, Kent, and E. Stewart, London. Eng. Pat. 21,048, Sept. 23, 1896.

GROSS linseed or other oil seeds are incorporated with the soap, with the object of neutralising any excess of alkali and of providing an excess of fatty matter not liable to become rancid.—C. A. M.

*Soaps, A New Manufacture of, and Process therefor.* A. Jolles, Vienna. Eng. Pat. 15,156, June 24, 1897.

ASBESTOS or infusorial earth, or both, with silicates such as steatite, all suspended in a finely-divided state in an aqueous alkaline solution, are mixed with the soap-body during saponification.—C. A. M.

## XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

### (B).—RESINS, VARNISHES.

*Spontaneous Combustion of Oils, Causes of.* W. Lippert. *Zeits. angew. Chem.* 1897, 434.

On exposure to air, old linseed oils absorb oxygen corresponding to an increase in weight of 15 or 16 per cent.; freshly expressed samples 17 to 18, or occasionally 19 per cent., but never as much as 20 per cent. When the oil is raw, or after it has been boiled without driers (e.g., lithographic varnish) the absorption only reaches a maximum after several days; but in presence of lead or manganese, the action may be complete in 20 hours. The danger of "spontaneous combustion" is therefore much greater in the latter case, and it is liable to occur whenever fibrous or porous materials, saturated with a drying varnish are exposed to the atmosphere. The actual "combustion" depends on the spontaneous ignition of the finely divided and pyrophoric carbon, which is produced as a result of the decomposition of the oil caused by the sudden rise in temperature; and the mass will only break into flame in presence of sufficient air. The same phenomena may be observed with turpentine varnishes containing resins as well as linseed oil; and a thermometer placed in the centre of a mass of cotton wool of about 0.5 metre in diameter, and saturated with an oil varnish, will soon reach 60° C., and in the present case the temperature rose to 135° in 15

minutes, and to 275° in three quarters of an hour. Later on still, vapours of unpleasant colour were emitted, and then the temperature suddenly rose to over 390° C., and the thermometer had to be removed.

The author's conclusions agree closely with those arrived at by Kissling (this Journal, 1895, 479); and he urges that whenever varnishing is done with a rubber in place of a brush, the old pieces of rag, cotton wool, &c., should be burnt immediately, and that fabrics coated with linseed oil should never be packed in heaps until the oxidation of the oil is fully complete.—F. H. L.

### *Asphaltites of Utah, The Uinta and the Uncompahgre.*

Eng. and Mining J., July 3, 1897, 10.

THE greater portion of the asphaltite is uinitaite or gilsonite, but there are also found utahite, elaterite, wartzite, albertite, ozokerite, and asphaltic limestones and sandstones. To prevent the accumulation of fire-damp in uinitaite mining, the walls are frequently washed with a copious deluge of water, to lay the dust. H. Hirsching found that numerous samples of uinitaite contain high percentages of light carburetted hydrogen compounds, free hydrogen, and free oxygen. Uinitaite or gum asphaltum is wholly soluble in benzine (petroleum spirit), turpentine, and other hydrocarbon solvents; it contains 56.46 per cent. of volatile matter, 43.43 per cent. of fixed residue, and 0.10 per cent. of ash. Uinitaite may be used as a base for black varnishes, paints, and japans, as an insulating and roofing material, and as a dip for pipe or wire to prevent oxidation and the corroding action of acids. More recently, it has been used as a dressing for leather, and in one form it furnishes a good imitation of patent leather, which it is practically impossible to crack. Utahite is partially vulcanised, and is only soluble to the extent of 40 per cent., the remainder being fixed bitumen. Albertite has the same composition as uinitaite, but is wholly insoluble. Elaterite (or mineral caoutchouc) is partially vulcanised asphaltum, and is stated to be the most elastic substance known. Ozokerite (or mineral wax) is used for making tapers. An artificial ozokerite is prepared by a secret process of the Assyrian Asphaltum Company from uinitaite by-products.

The asphaltic limestones contain a maximum of 72 per cent. of soluble bitumen and 11 per cent. of fixed bitumen; but the general average is 22 per cent. of soluble bitumen; the remainder is magnesian limestone and silica. The average percentage of total bitumen during 1896 was 29.70. This asphaltum contains no other organic matter, thus differing from the Trinidad and other species. Utah asphaltum is stated to be eminently suitable for street-paving purposes, although, according to some authorities, a mixture of asphaltic sandstone and asphaltic limestone gives a more lasting, finer grained, and better pavement.—A. S.

## XIV.—TANNING, LEATHER, GLUE, SIZE.

*Fermentation Phenomena in Tan Liquors.* F. Andreaseh. Imp. Research Laboratory, Vienna, *Der Gerber*, 23,536, 3.

*Sources of Nitrogen.*—The importance of these has been mentioned in the bacteriological portion of the research. It has been noted that (1) the amount of lactic acid in unused liquors, even after long standing (except sumac, myrabolams, and divi-divi liquors), is small; (2) in old liquors which have been used over and over again, it is large. The author finds the difference to be due entirely to the amount of nitrogenous nutriment furnished to the bacteria. The N was estimated in the principal tanning materials by Will and Varentz's and by Kjeldahl's methods; in the latter  $H_2SO_4$  only was used—no additions; it gave slightly higher values than W. and V.'s method, but the difference was not important. In the table given first on page 748, the nitrogen is reckoned on the dry substance.

It must be borne in mind that only part of the nitrogenous matter is soluble, and that some of this is precipitated by the tannin. The amount of soluble N in all the materials was therefore estimated (Table A) and fermentations conducted in the following media:—(1) Original tannin infusion, (2) the same, with addition of glucose, (3) peptone, (4) potassium phosphate and magnesium

sulphate, (5) sugar and peptone. The inoculating material consisted of four lactic acid organisms: a bacterium, a

baecillus, a micrococcus, and a yeast, all isolated out of tan liquors. The results of the fermentations by the bacterium and the yeast are given in Table B. The non-tannin in all the solutions was made equal. The amount of N in the liquors is seen to be much smaller than in the original material. Slightly more nitrogen was found in the liquors prepared by cold extraction. The concentration of the liquors made no difference to the amount of N dissolved; i.e., 100 parts of the material yield the same amount of soluble nitrogenous compounds whether 25, 50, or 100 grms. per litre be used.

The table shows the influence of the amount of N on the quantity of lactic acid produced. The amount of acid in all the materials is very small, and far less than met with in practice. The peptone used was free from albumins and albumoses.

[Glove] Leather Dressing, Employment of Canine Excrement and Putrefied Urine in. E. d'Huart. Bull. Assoc. Belge des Chimistes, 11, [2], 47—58 (this Journal, 1897, 687).

A. Canine Excrement.—The action of this material is essentially destructive, attacking the amorphous organic matter of the cutaneous tissue; but, being due to the vital activity of contained microbes, and not to the chemical substances present, cannot therefore be imitated by means of mixtures of the latter, but only by bacteriological cultures of the said organisms.

B. Putrefied Urine.—This liquor acts as a mordant for the dyes applied to the glove-leathers, and for this purpose may be efficiently replaced by a solution containing 15 to 20 grms. of ammonium carbonate—or their equivalent in potassium or sodium carbonate—per litre. Since, however, the influence of the various alkali carbonates on the shade of colour produced by a dye differs, it is found that to satisfactorily supersede urine, the solution must contain both fixed and volatile alkalis, the desired effect being obtained by the use of 10 to 15 grms. of sodium carbonate and 10 grms. of ammonium carbonate per litre—C. S.

## PATENTS.

*Leather-Board and Material suitable for being pressed into form for Decorative and other Purposes, or for use in Substitution for Leather, Floorcloth, and the like; Treatment of Waste Substances for.* T. H. Cobley, Dunstable. Eng. Pat. 13,096, June 13, 1896.

WASTE fibrous material and the wax, oil, albuminous and extractive matter derived from cotton-seed and shell are pulped together, boiled with silicate of soda, and the whole precipitated by addition of milk of lime. The alkaline liquor is then drained off from the precipitate. Waste leather or other animal substance is separately treated with sulphurous acid, and then added and thoroughly mixed with the first-obtained pulp, together with tanning agents or chromium compounds. The mass is then made into boards, or pressed, or moulded as desired.—C. O. W.

*Gelatinous Resilient Composition, applicable for Wheel Tyres and other Purposes.* D. Forbes and J. S. Weymouth, Bristol. Eng. Pat. 18,864, Aug. 26, 1896.

GLUCE is melted with water and subjected to heat, and to 76 parts of it 3 parts each of sulphur, sulphate of barium, a saturated solution of alum, and collodion are added. To the cold mixture are then added 3 parts each of sulphuric acid, glacial acetic acid, nitric acid, and formic acid. To soften the mixture, glycerin may be added. After setting, the mixture can be moulded into tyres and other articles.—C. O. W.

*Tanning Hides and Skins, Impts. in.* W. Clark, London. Eng. Pat. 21,210, Sept. 24, 1896.

THE skins prepared for tanning, and previously slightly swelled, are steeped for three days in a bath containing, in 1,000 c.c. of water, 4 grms. of lactic acid (73 per cent.), 2.6 grms. of potassium bichromate, and 0.9 gram of sulphuric acid. Subsequently an eight-days' treatment in a bath twice as strong and then four times as strong is given. The skins are afterwards washed, dried, and prepared as usual.—C. O. W.

*Waterproof Glue, Improved Manufacture of.* H. Gardner, London. Eng. Pat. 21,774, Oct. 1, 1896.

CASEIN, albumin, blood, or gluten are mixed with alkaline substances, such as calcium hydrate, potassium hydrate, sodium hydrate, the carbonates, silicates, borates, or phosphates of sodium or potassium. Preparations with from 15 to 50 per cent. of alkaline substance form a glue not soluble after a time at the ordinary temperature. Preparations with from 5 to 20 per cent. of alkaline substance form a glue which is applied in conjunction with heat.—C. O. W.

*Myrabolams, Obtaining Extracts therefrom; Impts. in or relating to Machinery or Apparatus for Treating.* S. Smithson, Beckmondwike. Eng. Pat. 12,399, May 19, 1897.

See under VI., page 737.

## XV.—MANURES, Etc.

## PATENTS.

*Fertiliser, An Improved.* C. Fell, Hanley, Staffordshire. Eng. Pat. 17,151, May 3, 1897.

THE fertiliser is prepared from excreta and urine, which are treated with sulphuric acid and mixed with sewage sludge. The mixture is then dried. The inventor claims the production of a manure containing 4 per cent. of nitrogen and 20 per cent. of phosphate.—D. B.

*Manure, A Consistent Friable; An Improved Process for making.* [Orthophosphoric Acid and Pent.] I. Kovacs, Budapesth, Hungary. Eng. Pat. 13,811, June 4, 1897.

IT has recently been shown that in many cases it is preferable to allow the phosphoric acid employed for manurial purposes to come into the ground in the form of orthophosphoric acid. Its practical use has, however, been prevented hitherto by the circumstance that it is very expensive, and

also that it does not come into commerce in the form of a consistent friable artificial manure, but in the form of a liquid. This form is, however, for agricultural purposes, not only costly, but its practical utilisation encounters many technical difficulties. The inventor overcomes these defects by the addition of absorbent substances, more particularly peat. By this addition the pulpy, stringy, soft product, produced by the free phosphoric and sulphuric acid and uncombined water, is converted into an artificial, easily distributed manure.—D. B.

## XVI.—SUGAR, STARCH, GUM, Etc.

[*Sugar Manufacture.*] *Checking Losses in Diffusion.* H. Pellet. Bull. Assoc. Belge des Chimistes, 11, [2], 58—64.

THE author's conclusions are that—

(1.) Provided the glucose or pre-existing reducing sugars be taken into account, the polarimeter and the copper methods will give precisely concordant results in the cases of the beet, the diffusion juices, and the spent slices.

(2.) As regards the copper methods for sugar estimations in beet and pulp, it is best to invert in the filtered liquor containing—as a result of sufficiently long, warm digestion—the whole of the crystallisable sugar.

(3.) Direct inversion of the pulp of fresh or spent slices may, however, be effected by the use of tartaric acid (1 gram per 100 c.c.), provided the digestion at 85—90°, or even 100°, be sufficiently prolonged to ensure the complete diffusion of the sugar and its conversion into glucose.

(4.) The final dilution of the solution from the fresh slices or the diffusion juice should be so adjusted that the quantity of sugar amounts to about 5 grms. per litre, so as to be under the same conditions as the normal cupric reagent and the titrated glucose, when their "titres" are determined.

(5.) For estimating the sugar in the spent slices by inversion, the solutions being more dilute, the Fehling's or Violette's reagent should be titrated by a solution of inverted glucose containing 1 gram per litre (reckoned in crystallisable sugar to save calculation).

(6.) For inversions in presence of pulp, it is absolutely essential to avoid the use of sulphuric acid.

(7.) For the indirect (polarisation) estimation of sugar in spent pulp, the slices should be finely comminuted and strongly pressed.

(8.) By taking all necessary care to ensure the exactitude of the elements required, there will be no undetermined loss in diffusion, either in sugar or polarimeter reading, whichever method be employed—that of polarisation or that by Violette's reagent.—C. S.

*Caroubin: A New Carbohydrate.* J. Effront. Comptes Rend. 1897, 125, 38—40.

FROM the seeds of *Ceratonia siliqua*—used as a cattle feed in Portugal—the author has isolated a new carbohydrate, *caroubin*, which has, empirically, the same composition as cellulose ( $C_6H_{10}O_5$ ). When purified, it forms a white, spongy, very friable mass, which yields, in contact with water, a syrupy liquid or jelly, 3—4 grms. of the substance being sufficient to convert 1 litre of water into a thick syrup. Caroubin is soluble in dilute HCl; the solution does not reduce Fehling's solution, and is optically inactive; but when boiled, a fermentable, dextro-rotatory, reducing sugar is formed. Caroubin appears to be widely distributed in nature; it occurs in rye and barley, and very probably enters into the composition of beer.

Caroubin may, in some cases, be with advantage used instead of gelose, for the preparation of the nutritive media employed in bacteriological work.—H. T. P.

*Caroubinose.* J. Effront. Comptes Rend. 1897, 309—311.

THE author has isolated a syrup by boiling powdered caroubin (50 grms.) with dilute sulphuric acid (1 litre), containing monohydrate,  $H_2SO_4$  (50 grms.). The product, which he names *caroubinose*, consists of a sugar ( $C_6H_{12}O_6$ ) which has about the same reducing action on Fehling's solution as dextrose, but its specific rotatory power is lower, viz.

$[\alpha]_D^{20} = 24$ . It ferments with yeast, forms a hydrazone  $C_{12}H_{11}N_2O_2$ , melting at  $183^\circ C$ , and an osazone  $C_{12}H_{12}N_4O_4$ , melting at  $198^\circ C$ .—T. A. L.

*Sugars, Iodometric Estimation of.* G. Romijn. Zeits. Anal. Chem. **36**, 349.

See under XXIII., page 765.

## PATENTS.

*Boneblack or Animal Charcoal, Process for Revivifying.* J. Wetter, Strand, London. From M. Weirich, St. Louis, U.S.A. Eng. Pat. 19,311, Sept. 1, 1896.

REFERS to Eng. Pat. 4351 of 1894 (this Journal, 1895, 178), for decarbonising and revivifying boneblack without charring. In this case, the apparatus therein described may be used, the process being one of oxidation, carried on at a comparatively low temperature. The drum or vessel used is heated to  $300$ — $400^\circ F$ ., a regulated current of air is passed through, and the boneblack, &c. fed regularly into one end of the drum and removed from the other. During the time it is within the drum, it is continually being raised and let fall by a revolving shaft having paddles.—R. S.

*Granulation of Crystallisable Liquids, An Improved Evaporating or Vacuum Apparatus for.* T. Grosse, Kiew, Russia. Eng. Pat. 27,477, Dec. 3, 1896.

See under I., page 719.

*Glucose or Sugar, Impts. in the Manufacture of.* L. P. Bauer, Peoria, Illinois, U.S.A. Eng. Pat. 15,295, June 26, 1897.

The apparatus consists of a sulphurous acid generator and means for the delivery of the gas into a charging tank containing starch sludge at the ordinary temperature. The sludge is saturated *in vacuo*, after which it passes into the converter, where it is heated under pressure to the point of conversion. The pressure is then removed from the product, and the sulphurous acid recovered in the form of solution by passing it into water.—J. L. B.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Re-kilning Malt, Effects of.* P. Schönfeld. Wochenschr. f. Brau. **14**, 137; Zeits. f. d. Ges. Brauw. **20**, [24], 319.

To remedy a deficiency in depth of colour and aroma, a malt from moderately heavy barley with a rather low percentage of nitrogen was replaced on the kiln and exposed to a temperature of  $106^\circ C$ . (the original kilning heat) for 8 hours. The objects in view were to some extent attained, the colour very slightly increasing, in a degree expressed by 0.1 c.c. of decinormal iodine (original shade = 0.3 c.c. decinormal iodine), and the aroma being improved. Other changes effected were: reduction of moisture from 4.7 per cent. to 1 per cent.; extract in dry matter increased from 68.8 per cent. by 0.8 per cent. in one example and by 2.2 per cent. in another; maltose (64 per cent.) in extract reduced by 4.5 per cent. and 5.6 per cent. in two samples; considerable weakening of the diastase, manifested by an increase in the time required for saccharification from 15 minutes to 23—25 minutes; slight decrease (0.06 per cent.) of nitrogen in dry matter.

The comparatively slight influence on the colour, caused surprise, in view of there being 5 per cent. of water still present before the re-kilning, and because of the rapidity of heating (to  $106^\circ C$ . in 2—3 hours) practised. It is con-

sidered that a greater effect would have been produced had the aërospire been more fully developed than in the parcel in question, in which it attained to but little more than half the length of the corns.—C. S.

*Yeast, The Nutrition of.* C. G. Matthews. J. Fed. Inst. of Brewing, 1897, **3**, 368—400.

The author treats this subject under the following heads:—

(a.) General considerations respecting the saccaromycetes and their vital functions. (b.) *Résumé* of facts ascertained concerning the constituents of yeast. (c.) and (d.) The inorganic and organic aliment derived from brewing materials. (e.) Experiments and experimental methods relating to yeast nutrition. (f.) Some practical deductions from the above sections.

In the experimental portion, it is stated that the yeast employed was *Saccharomyces coagulatus*—an organism well adapted for the investigation, inasmuch as it can be kept clean and free from bacteria and other ferments by washing. One litre of cold-water malt extract, or worts which were of two gravities (1.030 and 1.050), were pitched with 2 grms. of washed and pressed yeast taken from stock fermentations of hopped malt wort, or of wort prepared from commercial malt extract. The proportion of hops, when used, was 10 grms. to a litre of wort. The one-litre portions of wort were shaken up with air after pitching, and kept at a constant temperature of  $63^\circ F$ . for 15 hours, and subsequently at  $70^\circ F$ . At the end of the first 24 hours, the wort was usually poured into a beaker, the yeast remaining behind being shaken up to slightly aerate it, the wort poured back, and fermentation allowed to proceed until finished. It is pointed out that the experiments were designed to show the increase of yeast and the attenuation, but not the fermentative power. This increase of yeast is considered by the author to be the best guide to the suitability of the nutrient matters in the wort, and also to their quantity, provided that there is a sufficiency of fermentable matter present to ensure the yeast making the best use of the alimentary matter.

The principal conclusions drawn from the experiments are: (1.) That the boiling and coagulation of the albuminoids in cold-water malt extract make but little difference to the yield of yeast, allowing for the gravity of the worts. (2.) That unboiled cold-water malt extracts and worts give a very unclean fermentation, and that the yeast increase is thereby restricted. (3.) The boiled worts give a healthy fermentation and a good yeast crop, even in absence of hops. (4.) Hot mashes corresponding in strength to 10 per cent. cold-water mashes, give but slightly more yeast in the same volumes, showing that the sugar of the cold-water extracts is nearly adequate to secure the assimilation of the yeast nutrients. (5.) From the experimental evidence, the influence of hop extract, whether unboiled or boiled for a short time, is in the direction of diminishing the yeast output of malt wort.

Concerning the practical considerations, the author is of opinion that freshly prepared malt of good quality probably contains sufficient mineral and nitrogenous alimentary matter for the yeast, and it is almost certain that a considerable variation in the relation of these two classes of nutriment may exist, and that the amounts of each vary considerably. A variation of the phosphates, especially those of potassium and magnesium, may prove injurious to the yeast. The organic nourishment depends more especially on the malting process, and not so much on the original proteids of the barley. A fermentation may be sluggish from an excess of yeast nutriment or a deficiency; the latter may arise from poor malts or from an excess of substitutes. In such a case the wort may be pitched with a larger amount of yeast, or else with a stronger yeast, so bringing the potential of the yeast into the proper relation with the work which has to be accomplished by it.

—J. L. B.

*Alcoholic Fermentation without Yeast Cells.* Will. Zeits. für das Ges. Brauw. 1897, 363.

1. THE author has attempted to prepare the ferment (zymase), but without success; he, however, was provided

with a little of the yeast sap prepared by Buchner, and found it to have the properties ascribed to it by Buchner. He thinks it is not usually present in yeast, but that probably the pressed yeast employed by Buchner was in a state of decomposition.

2. Lindner, Dellbrück, and others (Wochenchr. für Brau, 1897, 364) have also attempted to prepare the ferment, but also without success. Doubt is thrown on the freedom from spores of Buchner's dried yeast (this Journal, 1897, 549), as in any preparation made by them having fermentative action, they have always found evidence of living yeast.—A. L. S.

#### *Fermentation in Media consisting of Solid Particles.*

T. Schläsing. Comptes Rend. 1897, 125, 10—13.

It has frequently been noticed that during the fermentation of solid media—e.g., the nitrification of soil, the fermentation of tobacco in the manufacture of snuff, &c.—the process comes to a standstill long before the medium has been exhausted, but may be restored to its original, or even greater vigour, by stirring or crumbling the mass. In fact, whenever fermentation has become weak, it may be accelerated by stirring the medium. At first sight it is naturally concluded that the recrudescence of fermentation is due to the aëration of the medium, brought about by agitation. The author shows, however, by experiments (with stable manure) that the acceleration produced by agitation is due to some cause unknown, and that aëration has little or nothing to do with the phenomenon, seeing that it obtains *in vacuo* just as well as in the presence of air. On the other hand, aëration unaccompanied by stirring has no effect on the fermentation.—H. T. P.

*Wines, Loss of Colour in ("Casse"); Influence of Iron Compounds.* H. Lagatu. Comptes Rend. 1897, 124, [25], 1461—1462.

A FERRIC salt, added to a wine of good colour (in quantity not greater than might occur naturally), produces a precipitate quite similar to that in *casse* wines.

A ferrous salt added to the same wine in bottle produces no effect, but when exposed to the air, *casse* sets in, following a course quite similar to the natural *casse*.

A ferrous salt and sulphurous acid added (the latter in such quantity as would be used to remedy a tendency to natural *casse*) to the same wine, produce no result even after prolonged exposure to air.

Analysis of wines liable to this modification, before and after the *casse*, has shown that after exposure to air almost the whole of the iron of the wine is found in the precipitate.

Probably, then, a wine subject to *casse*, contains ferrous salts, which on exposure to air (with or without the aid of an oxidising diastase) become ferric salts, and then precipitate the tannins, among which is to be reckoned the colouring matter. An oxydase may be essential; but, if so, it is to oxidise the ferrous salt, not directly to render the colouring matter insoluble. This view throws light on the influence of tartaric and citric acids on the *casse*, suggests questions as to certain changes in white wines, and as to the practice of washing with ferrous sulphate solution—problems which the author is now endeavouring to solve. (See also this Journal, 1897, 156, 347.)—J. T. D.

## XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A).—FOODS.

*Heavy Metals in Cheese, Note on the Presence of.* A. H. Allen and F. H. Cox. Analyst, 1897, 22, 187—188.

The authors consider that the metallic lead recently found by F. W. Stoddart in a sample of Canadian cheese, was probably due to the addition of a lead salt—probably the acetate—to the cheese.

Two samples of "cheese spice," used to prevent the heaving and cracking of cheese, were examined, and it was found that one sample consisted of crystallised sulphate of zinc, whilst the other was a solution of sulphate of zinc corresponding to 38 per cent. of the crystallised salt. It was found that 99.28 per cent. of the total zinc employed, passed into the curd, whilst the remaining 0.72 per cent. remained in solution in the whey. R. Bodmer recently examined two samples of cheese containing zinc, and found that one, a pale coloured cheese, contained 0.84 grain of zinc, or 3.7 grains of the crystallised sulphate per lb.; and the other, a reddish cheese, contained 0.56 grain of zinc, or 2.5 grains of the crystallised sulphate per lb. It is stated that sulphate of copper was formerly added to cheese, and that the green mould in certain kinds of cheese has been initiated by the insertion of copper or brass skewers.

### PATENTS.

*Yeast, Impts. in the Production of Compressed Bakers'.* M. P. Hatschek, Middlesex. Eng. Pat. 5908, May 9, 1896.

MALT combs, with or without bran, or peas, lupines, &c., are mashed like grain with malt, or only steeped in water at 140° to 200° F., with an addition of a small percentage of mineral or organic acid, dependent upon the amount of infection in the raw material or water. This extract is mixed with 1 to 3 lb. of maltose or other sugar for each pound of compressed yeast to be produced. The seed-yeast is introduced into the fermenting vat containing the above-described nutrient liquid, the whole being maintained at a temperature of 85° to 87° F., and filtered air pumped in by means of a rouser or other device. Boric acid or its salts, in the proportion of 1 part to 5,000—10,000 of fermenting liquor, is added to prevent infection or the formation of undesirable organic acids. When the fermentation is finished, the wash is cooled to 72° F. by adding cold water, and allowed to stand for 10 to 12 hours, the yeast being then removed by decantation and straining through bags. It is again washed with water containing boric acid in the previously mentioned proportions, and pressed, and packed in the usual manner. This process is also applicable for the manufacture of yeast for distilling purposes.—J. L. B.

*Fat or Fatty Waste, Treatment of.* T. Coad, East Ham, Essex. Eng. Pat. 15,336, July 10, 1896.

ALL traces of decomposition and dirt are removed by mixing the waste fat with an antiseptic (preferably boric acid), extracting the liquid fat (preferably by dry heat), boiling it in a solution of gelatin, and precipitating the latter (preferably with alcohol, 60 over proof). When washed and dried, the fat is said to be fit for food.—C. A. M.

*"Separated" Milk, A Method of Treating and Employing the same in the Making of Bread, Biscuit, and other Food stuffs.* H. Higgins, Cambridge. Eng. Pat. 15,471, July 13, 1896.

THE "separated" milk is evaporated to dryness or to a suitable consistence, and mixed with any or either of the following substances:—Flour, meal, semolina, tapioca, sago, oatmeal, gluten, cane sugar, milk sugar, lactose, glucose, animal or vegetable fat, and flavouring and colouring matters. Or these substances may be mixed with the caseinogen obtained from the "separated" milk by precipitation with an acid. Claim is also made for the use of such combined products as flour in the manufacture of bread, biscuits, and the like.—C. A. M.

*Caseinogen, Method for Causing the Separation of, from "Separated" Milk, and its Preservation in a Dry State.* H. Higgins, Cambridge. Eng. Pat. 16,860, July 29, 1896.

THE milk is agitated with a suitable proportion of an acid, such as acetic, hydrochloric, nitric, or phosphoric acids, and the separated caseinogen washed free from acid and lactose, and dried in a suitable drying chamber.—C. A. M.

*Liquid Extracts of Coffee or other Substances, Impts. in the Manufacture of, and in Apparatus for the Purpose.* J. F. Duke, West Dulwich, London. Eng. Pat. 19,675, Sept. 5, 1896.

IN order to avoid the necessity of concentrating the extracts by evaporation and the consequent loss of aroma and fragrance, the coffee or other substance is extracted in a series of connected hermetically closed vessels by means of boiling water, which is forced by pressure from vessel to vessel throughout the series, commencing with that in which the coffee is nearly spent. From time to time the vessel nearest the boiler is removed, the others moved a stage nearer, and a new vessel with a fresh charge placed next to the receiver.—C. A. M.

*Preventing the Decomposition of Animal, Vegetable, or other Alimentary Substances or Products: An Improved Method of.* K. L. O'Doherty, Brisbane, Queensland. Eng. Pat. 6915, March 16, 1897. (Under Internat. Convention.)

THE substances are surrounded with an atmosphere of nitrogen in closed receptacles, and maintained at a temperature of from about 28—50° F. Similarly, in defrosting hard frozen substances, such as meat, decomposition is prevented by filling the chamber with nitrogen, and letting the temperature rise, to about 40° F., until the defrosting is complete.—C. A. M.

*Milk, An Improved Process of Preserving.* W. T. Murray, Southland, New Zealand; at present, Wimbledon, London. Eng. Pat. 10,873, May 1, 1897.

THE milk is heated to boiling point,  $\frac{1}{2}$  lb. to  $1\frac{1}{2}$  lb. of glycerin with about five times the volume of water added to each 100 lb., and the whole concentrated *in vacuo* to one-fourth or one-fifth its original volume.—C. A. M.

*Cocoa Husks, A New or Improved Extract of, and a Method of Preparing the same.* H. Christensen and R. Haumann, both of Copenhagen. Eng. Pat. 14,624, June 16, 1897.

THE husks are extracted by soaking in water or steam, then boiled with water, and the resulting liquid separated from refuse and concentrated in open pans or *in vacuo*. The theobrominous extract may be used alone or as an admixture with cream, chocolate, &c.—C. A. M.

## (B.)—SANITATION; WATER PURIFICATION.

*Garbage, Disposal by the Merz System.* J. Pownall. Proc. Inst. Civil Eng. 1897, 128, [2]; Paper No. 2962.

THE Merz system is an extraction process, in which a volatile hydrocarbon solvent is used. At St. Louis, Mo., U.S.A., naphtha is used, and the products obtained are grease and a residual fertiliser of some value. The garbage is discharged from the waggons into receiving tanks, from which it is drawn as required through a door in the bottom, and, after sorting, it is fed into the driers through 12-in. feed pipes. The driers consist of long chambers, elliptical-shaped in cross section, and are supplied with steam jackets over two-thirds of the perimeter on the lower side. The garbage is agitated by a central shaft and reel, and the condition of the material is ascertained from time to time by inspection through a test hole in the rear of the apparatus. A period of four to five hours at 250° F. is required to complete the drying operation, and the vapours driven off, amounting to 65—75 per cent. of the total weight, pass to water-column condensers, the condensed liquids passing to the sewer, and the uncondensed vapours being conveyed through pipes to the retorts in the boiler furnaces, where they are consumed. The dried material is discharged automatically from the rear of the drier into a screw conveyor, and thence, by means of an elevator, is carried to the extractor room. The extractors consist of cylindrical tanks of similar construction to the receiving tanks, but with the addition of the necessary appliances for regulating the admission of the solvent and steam. The tanks have perforated false bottoms, between which and the lower faces of the tanks are placed coils, so that a gentle heat may be applied to the material under treatment. The garbage is allowed to soak until all grease, oil, and fatty matters are taken up by the solvent (two to four hours), and the solution is then drawn off. The naphtha is distilled off and condensed for further use, and the residual grease is purified. The process is said to be automatic and continuous.—A. S.

*Air in the Purifying and Revivifying Houses of Gas-works, Contamination of the.* H. Drehschmidt. J. für Gasbeleucht. 1897, 40, 517—520.

BREATHING the contaminated air that prevails in the purifying and revivifying houses was stated to have an injurious effect on the health of the workmen employed in those houses at the Berlin municipal gasworks. Investigations were undertaken at the Müllerstrasse works (Berlin), chiefly by Dr. H. Wolf.

THE chief poisonous constituents of coal-gas are ammonia, hydrocyanic acid, sulphuretted hydrogen, carbon bisulphide, other gaseous sulphur compounds, and carbon monoxide. All but the last are absorbed by oxide of iron, and are evolved from it during revivification. They were therefore sought for in the air above the revivifying floor, at the height of the workmen's heads. In modern works only 1 to 20 grms. of ammonia per cubic metre of gas reach the purifiers. All but a trace is retained there, chiefly as carbonate. The ammonia in the air was estimated by aspirating 400 to 600 litres of air through  $\frac{1}{20}$ N sulphuric acid. Above the revivifying floor, 0.00002 to 0.00004 vol. per cent., and in a purifier in course of being emptied, 0.00041 vol. per cent. of ammonia were found in the air. Lehmann has observed that 0.05 vol. per cent. in air produces irritation, but that men can become accustomed to 0.03 to 0.05 per cent. In works where ammonia is nearly removed from the gas before it enters the purifiers, no injury therefore need be feared to the health of the purifier workmen from its inhalation.

Several methods of estimating hydrocyanic acid in air were tried, and proved unreliable. Eventually, estimations were made as follows:—500 to 600 litres of the air were drawn, at the rate of 50 litres per hour, through two absorption vessels containing water holding in suspension fine mercuric oxide. The water was subsequently made up to a known volume filtered, and a known volume of the filtrate removed, and treated with ammonia and zinc dust. After making up to a known volume and filtering, a given fraction of this was taken and titrated with silver solution,

according to Volhard's method (J. für Gasbeleucht. 1892, 221). Blank estimations were made, to ascertain the allowance to be made for impurities in the reagents. The air above the revivifying floor, with oxide fouled once or twice only, was found to contain 0.000466 and 0.000414 in two tests; and with oxide fouled 13 to 14 times, 0.00012 vol. per cent. of hydrocyanic acid. With foul oxide which had lain some time on the floor, only 0.00002 was found. The quantity which renders air harmful does not seem to be recorded, but Weyl states that in the cyanide industries, where the quantity in the air must be much greater than the above, cases of cyanide poisoning are very rare. Injury to health from hydrocyanic acid in the air of purifying houses appears improbable.

Lead acetate paper scarcely indicated traces of sulphuretted hydrogen even on prolonged exposure to the air above the revivifying floor. This air proved, by aspiration through heated platinised asbestos, to contain total sulphur compounds equivalent to 0.000303 vol. per cent., or 0.196 mgrm. per cubic metre of carbon disulphide. Weyl states that 0.5 to 0.8 mgrm. per litre is not injurious.

Carbon monoxide was sought for in the air of a freshly opened purifier. Samples of the air were collected by displacement of water, and the carbon monoxide therein was estimated by drawing the air through strong solution of potash and a glowing platinum capillary into standardised solution of baryta. The results of five tests showed 0.006, 0.027, 0.038, 0.038, 0.032 vol. per cent. of carbon monoxide in the air. W. Hempel's researches show that 0.043 per cent. does not cause symptoms of poisoning. It is not a cumulative poison, as the hæmoglobin compound of carbon monoxide is not very stable.—J. A. B.

*Sewage Water, Purification of, by Filtration through Peat.* G. Frank. Gesundheits-Ing. 1896, 345 et seq., and Proc. Inst. Civil Eng. 1897, 128, [2], 27.

THE author considers that the unsatisfactory results hitherto obtained by the filtration of sewage water through peat as a means of rendering the sewage available for manurial purposes, is probably due to the air which is always present in finely divided peat. The peat should be reduced to a fine state of division under water, and be there brought to the condition of sludge, which latter proves to be an excellent filtering material. It was found that the bulk of the impurities and germs were removed from sewage water by filtration through this material, and that the resultant peat sludge was possessed of considerable manurial value. The filtered effluent was sufficiently pure to be discharged into a river.—A. S.

#### PATENTS.

*Sewage Purification for Country Houses, Impts. in.* A. H. Constable, Penhurst, Kent. Eng. Pat. 19,056, Aug. 28, 1896.

THE sewage is discharged through two underground tanks having V-shaped bottoms, and the upper portions of both having a division or tongue in the centre at right angles to the direction of flow. A chamber between these tanks contains a small water wheel or turbine, a receptacle for lime, and a screw for mixing the lime with the effluent. The crude sewage flowing into the first tank and under the partition, deposits most of its suspended matter. When the liquid has risen to a certain height, some of the clear upper portion is discharged, by means of a siphon, through the intermediate liming chamber into the second tank, in which the lime precipitate deposits, and the clarified effluent flows away.—L. A.

*Tanks for the Precipitation of Sewage and Foul Liquids, Impts. in and relating to.* The Magnetite Sewage and Water Purification Company, Ltd., and G. H. Skelsey, Manchester. Eng. Pat. 21,235, Sept. 25, 1896.

THE improvements are intended to facilitate the removal of the sludge. The lower part of the tank is formed into two or more parallel chambers having sloping sides, which conduct the sludge to a point at which a branch pipe opens, through which the sludge can be drawn off. Each branch

pipe communicates through a valve with a main pipe, so that the chambers can be emptied singly or together. The sewage flows through the tank from chamber to chamber, and is collected by suitable baffles and partitions.—L. A.

*Sewage or other Liquids, Impts. in Apparatus for the Treatment of.* D. Cameron, F. J. Connin, and A. J. Martin, Exeter. Eng. Pat. 23,042, Oct. 17, 1896.

THE improvements comprise (1) Means for discharging the contents of a tank along an extended line, consisting of a slotted or perforated pipe placed at right angles to the line of flow; (2) Means for the removal of mud, consisting in sloping the floor of the tank to a line or lines along which slotted or perforated discharge pipes are laid, and providing other perforated pipes for flushing the mud towards the discharge pipes; (3) Making the precipitating tanks wedge-shaped, the inlet for sewage being at the narrow end and the outlet at the broad end, thus avoiding eddies and reducing the rate of flow towards the outlet, so as to promote the subsidence of the precipitate; (4) Automatic mechanism for discharging the effluent from a tank intermittently on to a filter bed, consisting of a bucket at the end of a lever which descends when full, and raises the discharge valve; also automatic gear discharging the contents of a number of tanks in rotation; (5) Automatic mechanism for distributing the effluent evenly over the surface of a filter bed by delivering it in successive fractions through a number of separate channels distributed over the surface of the filter bed, consisting of a water-wheel and gear, which causes valves connected with the different channels to open and shut in rotation, or a revolving basin which discharges successively into channels radiating from the basin as a centre.—L. A.

*Sewage and the like Precipitating and Filtering Tanks, Impts. in.* J. E. Bennett and H. Beresford, Manchester. Eng. Pat. 1391, Jan. 19, 1897.

THE precipitating tank is provided with a number of inclined partitions, which conduct the precipitate or sludge into hopper-shaped depressions at the bottom, from which it can be drawn off through siphon pipes. Suspended in the water at the far end of the precipitating tank is a smaller tank or box, the bottom of which is a filter or strainer, through which the effluent rises into the box and overflows through a flexible pipe into another small tank suspended outside the precipitating tank. The two small tanks are connected by a chain, which passes over two pulleys; and, by means of suitable automatic mechanism when the outside tank has become full of clear effluent, it descends, raising the filter tank and causing the clear liquid in it to flow back through the filter into the main tank, thus detaching the solid matter which has accumulated on the under side, and cleansing the filter. When the outside tank has descended a sufficient distance, a valve in the bottom is automatically opened and the liquid is discharged. The filter tank, which is then the heavier, descends again to its former position.—L. A.

*Treatment of Water or other Liquids with Powdered Materials, Impts. in Apparatus for the.* Maignen's Filtre Rapide and Anti-Calcicole Company, Ltd., and A. A. Ellis, London. Eng. Pat. 5823, March 4, 1897.

IN existing apparatus, where mechanism actuated by a water-wheel is made to discharge from a receptacle a given quantity of dry powder at regular intervals into the water to be treated, it is found that the quantity of powder discharged gradually increases as the receptacle gets empty, because the resistance to the movement of the stirrer decreases. To remedy this defect, the receptacle is made in the form of a tall cylindrical box having several orifices one above another, each provided with a regulating shutter. Inside the box is a vertical spindle having ejector arms, opposite to each orifice, actuated by the water-wheel. When the box is quite full of powder and the resistance to the movement of the stirrer greatest, the powder is ejected from every orifice; but as the level of the powder falls and the decreased resistance causes the speed of the stirrer to increase, the number of orifices from which the powder is discharged becomes less, and by a proper adjustment of the

sizes of the openings the amount of powder ejected may be made exactly proportional to the quantity of water passing over the wheel.—L. A.

*Sterilising, Disinfecting, and Similar Purposes, and for cultivating Bacteria; Impts. in or relating to Apparatus for use in* E. Fournier, Paris. Eng. Pat. 7888, March 26, 1897.

The apparatus consists of a boiler or digester having a loose cover fixed in position by means of hinged bolts and thumb-screws, with an adjustable safety valve and warning whistle. It contains water, which is heated by a spirit lamp with two burners—one large, for rapidly heating up, and the other smaller, for maintaining the desired temperature. Both burners have arrangements for adjusting the size of flame. The articles to be sterilised are placed in receptacles which fit loosely within the digester, and are either closed for dry sterilisation, or of gauze for direct steam contact. The temperature depends upon the pressure, which may be several atmospheres and is regulated by the safety valve. In using the apparatus for fumigation with formaldehyde, &c., a special inner vessel is used, in which the disinfectant vapours are produced under pressure and ejected through a pipe and cock having two independent passages—one enabling steam to pass from the digester for the purpose of heating the tube conveying the disinfectant vapours, the other passage being in communication at one end with the vapour vessel and at the other end with a ball, in which condensed vapours may collect, and with a flexible continuation, the end of which may be introduced into any suitable aperture for distributing the disinfecting vapours.

—L. A.

### (C).—DISINFECTANTS.

*Paraformic Aldehyde as an Antiseptic.* B. H. Paul and A. J. Cowley. Pharm. J. 1897, **59**, 107.

SINCE the solid polymer of formaldehyde is readily converted into the liquid state by simply heating with water, it is suggested that, for convenience in handling and transport, it might, with advantage, be prepared commercially in this condition. It was found that, when boiled with water under an inverted condenser, in the proportion of 4 : 10, solid paraformaldehyde was converted into the liquid condition in about two hours. Under pressure in a sealed tube, the time taken to effect this transformation was rather longer. Paraformaldehyde is fairly volatile in the air at ordinary temperatures, about 50 per cent. volatilising in 24 hours.

For the quantitative determination of formic aldehyde in either condition, the authors find the gravimetric determination of the amount of hexamethylene tetramine formed on the addition of ammonia to formaldehyde, yields the most satisfactory results.

The ammonium compound is evaporated until viscid, and then dried to constant weight under the desiccator. On exposing an aqueous solution of formaldehyde to the air until it dries up, there appears to be formed, not a true para compound, but a mixture somewhat resembling the substance  $(CH_2O)_2$  described by Tollens and Mayer as being formed when formic aldehyde is evaporated over sulphuric acid. The authors found that this body melts at about 131 C., and is more soluble in water. The polymer obtained by adding sulphuric acid to liquid formaldehyde melted at 170 C. The variation in the melting point ascribed to paraformaldehyde is probably due to the presence of an admixture of these two bodies.—J. O. B.

### PATENTS.

*Formic Aldehyde, Impts. in the Production of Vapours of, and Apparatus for the same.* J. J. A. Trillat, Paris, France. Eng. Pat. 20,773, Sept. 19, 1896. (Date claimed under International Convention, Feb. 25, 1896.)

A process and apparatus are claimed for the production of formaldehyde vapours from the solution, without polymerisation, by heating in an autoclave with a neutral salt (calcium chloride) to a pressure of three or four atmospheres and then discharging the vapours.—A. C. W.

*Dressing or Wash for Hop and other Plants, Improved Compositions for use as* B. S. Dyer, London. Eng. Pat. 9566, May 5, 1896.

PICRIC acid ( $\frac{1}{2}$  to  $\frac{3}{4}$  lb.), soft soap (5 lb.), and "liver of sulphur" ( $\frac{1}{4}$  lb.) are made into a paste with a little water and diluted with more water to 100 galls. The proportions may be varied.—L. A.

*Destroying Insects on Plants, Impt. in Preparations for, and for Similar Purposes.* E. C. Hughes, Manchester. Eng. Pat. 16,773, July 29, 1896.

THE preparation claimed, is a mixture of nicotine with ground mineral substances (sand, silicious earth, &c.), and is used in a dry state for the purpose of fumigation and also for mixing with the soil.—L. A.

*Formic Aldehyde Vapour, Improved Means of Distributing.* La Société Chimique des Usines du Rhône, Lyons, France. Eng. Pat. 20,622, Sept. 17, 1896.

THE claim is for the means of distributing formaldehyde vapour, which consists in mixing the aldehyde solution with a liquid of very low boiling point (such as ethyl chloride) without chemical action on the aldehyde, and in enclosing the mixture in suitable vessels provided with a jet.—A. C. W.

## XIX.—PAPER, PASTEBOARD, Etc.

*Millboard for Bobbins.* Papier Zeit. 1897, **22**, [29], 1018.

FOR the making of bobbins which do not scale or split, the process given is as follows:—Sheets of millboard to make the required thickness are pasted together with a mixture of starch paste and 30 per cent. of water glass, slightly dried, punched out, and treated with a quick-drying oil. The discs for making the bobbins thus obtained, are subjected to hydraulic pressure for about 24 hours, by which they are rendered very hard. They are then turned in a lathe. No intense heat is used, and the discs thus made, it is said, do not split.

The millboards used are not sized at all, and the paste used should be spread as evenly as possible, the pasted boards being well dried.—S. P. E.

*Paper, Mechanical Testing of.* S. Ferenczi. Zeits. angew. Chem. 1897, 436.

IN order to test the capacity of a sample of paper to bear rubbing against itself and to resist crumpling, Pfuhl has devised a mechanical arrangement. The strip of paper is fastened at one end on the outside of a metal cylinder which rotates within a semi-circular sheet of rubber clamped to a similarly shaped metallic casing. Into the space between the rubber and the case, air is driven with a pump, and the pressure is registered by means of a gauge. As the inner cylinder is rotated, the paper doubles back on itself and is squeezed between the two surfaces, the operation being either continued till the strip is destroyed or the air pressure increased until the same effect is attained. Tested in this instrument, the six classes into which the Prussian Paper Testing Institute divides paper according to its power of resisting hand-rubbing, will bear pressures of (1) over 70, (2) 48—70, (3) 26—48, (4) 16—26, (5) 6—16, and (6)  $\frac{1}{2}$ —6 cm. of mercury when the saturation of the atmosphere is 65 per cent.; but the inventor prefers not to use the pump above 48 cm., but rather to repeat the rotation of the cylinder.

Schopper has also constructed an apparatus for the same purpose, in which a strip of paper 115 mm. long and 16 mm. wide is stretched by springs horizontally at a tension of 0.5 to 1 kilo. At the middle of its length it passes between two pairs of guide rollers, and through a slot cut in a bar of metal 5 mm. thick, which is driven backwards and forwards at right angles to the paper by means of a hand-wheel and eccentric pin. The number of transverse thrusts, recorded by a counter, which the sample will bear before breaking, varies from 0 to 800 on the above scale.—F. H. L.

## PATENTS.

*Paper Pulp and the like, Impts. in or relating to the Manufacture of Articles from.* E. C. de Segundo, Middlesex. Eng. Pat. 15,604, July 14, 1896.

HYDRAULIC moulds, having fixed and movable sections and operating normally to the surface of the pulp, are used to form articles from pulp, &c. For ornamented articles the faces of the moulds are grooved or sunk as required. The pulp may be heated whilst under pressure by having the moulds steam-jacketed. The water from the pulp is got rid of by perforating the moulds, or by forming the faces of the mould with wire-gauze laid over grooves or escape channels. An important feature is that the guides of the sections are not allowed to present sharp angles to the surface of the article being formed, but are bevelled off or otherwise arranged so as to form clearances. For hollow articles, collapsible cores may be used.

Starch or other binding material may be used with the pulp, the heating of which would firmly bind the material together.—S. P. E.

*Paper, Cardboard, and Similar Materials; Impts. in and connected with Superficially Coloured.* C. H. Voigt, Leipzig-Plagwitz, Germany. Eng. Pat. 12,304, May 18, 1897.

THE improvement consists in the use of a new composition to serve as "binding material" in place of the size, consisting mainly of glue, hitherto employed to mix with the pigments. By the use of this new composition it is said the otherwise necessary sizing of the paper previous to the application of the film of colour, may be dispensed with, and the subsequent printing of several colours on the same sheet, is facilitated. The composition is prepared as follows:—

About 100 parts of starch or other mucilaginous vegetable substance, such as agar-agar or carrageen, and about 2 per cent. of solid alkali hydrate are mixed with 300–500 parts of water, and subjected to pressure at a temperature ranging between 110–200° C. until a uniform mass has been produced. The colouring matter is subsequently incorporated in this compound, to which wax or soap may be added if required.—I. S.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Monazite.* H. B. C. Nitze. J. Franklin Inst. 1897, 144, 127–133.

THE development of incandescent gas lighting caused an increase in the output of Carolina monazite sand from 130,000 lb. in 1893 to 1,900,000 lb. in 1895. The output fell, however, in 1896 to 17,500 lb., owing to the increased competition of the Brazilian field, where the sand occurs naturally concentrated on the beach, requires no cleaning, and may be loaded directly into ships and carried as ballast. Monazite is essentially a complex tribasic phosphate of cerium, lanthanum, and didymium, with variable percentages of thorium and silica. The two last-named are believed by some to be present in combination, whilst others assume that the thorium is present as a constituent of the phosphate. The percentage composition of four samples from the United States ranged as follows:— $P_2O_5$ , 26.1 to 29.3;  $Ce_2O_3$ , 29.9 to 37.2;  $La_2O_3$ , 26.6 to 31.6;  $ThO_2$ , 1.5 to 14.2;  $SiO_2$ , 0.3 to 2.8; and  $H_2O$ , 0.2 to 0.7 per cent. The value depends mainly on the percentage of thorium (as that element is chiefly required for incandescent lighting), and this varies from 4 to 7 per cent. in the best Carolina grades. The mineral usually crystallises in monoclinic tables, short columns, or small needles, from 0.05 to 1 in. long, but occasionally attaining to a length of 5 ins. It is brittle, has a hardness of 5–5.5, and a specific gravity of 4.6–5.3; the lustre is resinous to waxy, bright in fresh crystals, but weathering dull, or even becoming coated with a light brown earthy substance. When pure it is transparent, but it is translucent or opaque in the more impure specimens, and it has a yellow, brown, or greenish-yellow colour. It occurs in granitic rocks and varieties of gneiss, and has been found in apatite, cyanite, and vein quartz. The main

constituents of granite may all contain monazite as intergrowths, but it is generally confined to the felspar. Zircon is almost always concomitant. In the United States it is found only in North and South Carolina, within an area of about 2,000 sq. miles. Most of the stream deposits have been worked for gold. The gravel beds are about 1 to 2 ft. deep, and rarely exceed 12 ft. in width; they contain from almost nothing up to 1 or 2 per cent. of monazite. In Brazil the principal monazite (beach) sand is on the island of Alcobaca, to the extreme south of Bahia, but the mineral is also found in the gold and diamond placers of Bahia, Minas Geraes, Rio de Janeiro, and Sao Paulo. It also occurs in the placers of Rio Chico (U.S. of Colombia), of Bakakui (Sankara river, Ural mountains), and in Siberia.

In Carolina the monazite is obtained by washing the sand in sluice-boxes, after the manner of placer gold. These boxes are 8 ft. long by 20 in. wide and deep, and require the service of two men—one to charge the gravel on to a perforated plate at the upper end, the other to agitate the contents with the aid of a gravel-fork or perforated shovel, in order to float off the lighter sands. The boxes are cleaned out periodically, and should yield about 40 to 70 lb. of cleaned monazite each *per diem*. Two or more boxes may be used in succession at different levels. Magnetite is eliminated from the dried sand by means of a large hand-magnet, but many heavy minerals (zircon, garnet, rutile, ilmenite) cannot be separated by these methods, and there may be 30 to 35 per cent. of foreign matter left even in good samples of washed monazite. The grade may often be improved up to 85 per cent. monazite by a system of winnowing, &c. But the cost of such processes is considerable, and the gain is not always commensurate. The author has produced a clean product with only an insignificant loss in the tailings by jigging, and then passing the jig concentrates over a Wetherill magnetic separator. Any gold in these concentrates could be recovered by amalgamation in riffle boxes. The working of decomposed rock *in situ* is not usually remunerative, on account of the small proportion of monazite present, unless the rock be at the same time gold-bearing.—W. G. T.

*Monazite in Idaho.* W. Lindgren. Eng. and Mining J. 1897, 64, 69. From the Amer. J. of Science.

A SAMPLE of sand washed from the lake beds near Idaho City, consisted of: ilmenite in sharp hexagonal crystals, but no magnetite; zircon, also in extremely sharp crystals of a slightly brownish colour; and abundant yellow or greenish-yellow grains rarely showing crystallographic faces; the refraction and double refraction of this mineral were very high, the hardness not much over 5. The ilmenite was eliminated by the electro-magnet, and an analysis by W. F. Hillebrand, of the remaining powder containing about 70 per cent. of the yellow mineral, showed that it was a phosphate of the cerium metals, the approximate amount of the oxides of the latter being 48 per cent.; in these about 1.2 per cent. of thorium was found. Another sample from the alluvial gold washing in Wolf Creek, Placerville, when cleaned from quartz, &c., appeared as a heavy dark sand, consisting of a black iron ore (ilmenite), rounded crystals of red garnet, sharp crystals of zircon, and irregular grains of a dark yellowish-brown mineral with a waxy lustre, sometimes showing crystallographic faces. There was practically no magnetite present. On a qualitative analysis of the sand, W. F. Hillebrand found present phosphoric acid, cerium metals, and thorium. The yellowish mineral is therefore in all probability monazite. Although the monazite occurs in considerable quantity, it is doubtful whether the mineral can be profitably extracted, except possibly as a by-product obtained from the gold washings.—A. S.

*Arsenic, Some Soluble Compounds of.* G. G. Henderson. Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1416], 146.

METHODS of preparation are described of the soluble combinations of arsenic with the acid tartrates and citrates of the alkali metals. These compounds are analogous to tartar emetic, the antimony being replaced by arsenic.

Sodium arsenio-tartrate,  $\text{AsO}_3 \cdot \text{NaC}_4\text{H}_4\text{O}_6 \cdot 2\frac{1}{2}\text{H}_2\text{O}$ , crystallises from water in groups of colourless prisms, from 50 per cent. alcohol in colourless plates. It loses its water of crystallisation when heated to  $105^\circ \text{C}$ ., or when left to stand over sulphuric acid in a vacuum, but the dried salt may be heated for several hours at about  $200^\circ \text{C}$ . without decomposing. It is easily soluble in water, and the solution, which is very poisonous, has a sweet taste and is of an acid reaction. The physiological action of this salt is practically the same as that of "liquor arsenicalis." Ammonium arsenio-tartrate crystallises in small lustrous needles, readily soluble in water, but less stable than the sodium salt. The potassium salt forms a white crystalline powder, which is decomposed by water into arsenious oxide and potassium hydrogen tartrate. The arsenio-citrates form colourless crystals, easily soluble in water and fairly soluble in dilute alcohol; these salts decompose when heated in aqueous solution.

—A. S.

*Conium Maculatum. Note on the Pharmacy of.* E. H. Farr and R. Wright. Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1116], 136.

THE authors prepared standardised products of conium and solutions of its alkaloids for physiological examination. A fluid extract of dried nupur fruits was prepared by successive percolation, and was standardised so as to contain 2.5 per cent. of total alkaloidal hydrochlorides. A corresponding solution of the mixed alkaloids of the same fruits was prepared in a similar manner, the alkaloids being extracted from the percolate; this solution was made up to the same strength as the preceding one. Succus fruct. conii was obtained by maceration and pressing, using first rectified spirit and then a mixture of spirit and water, and the extract was found to contain 0.7 per cent. of total alkaloidal hydrochlorides. Solutions were also prepared of pure conine hydrochloride, conhydrine hydrochloride, and of pseudoconhydrine hydrochloride.—A. S.

*Conium Maculatum. Certain Preparations and Active Principles of; Note on the Action of.* W. Findlay. Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1116], 137. (See preceding abstract.)

THE author, on examining the preparations described in the preceding abstract, found that conine and the mixed alkaloids are the most toxic, the lethal dose being, for conine, 37 mgrms. per kilo. of body weight; for the mixed alkaloids, 39 mgrms.; for conhydrine, not less than 257 mgrms.; and for pseudoconhydrine, above that quantity. The fluid extract appears to be as active as conine. The results obtained with the succus were uncertain, on account of its low percentage of alkaloids.—A. S.

*The Aloines.* E. Leger. Comptes Rend. 1897, 125 185—188.

FROM different species of aloes, crystalline substances have been extracted; to these, names have been given recalling the country of origin. According to Groenwold (Arch. der Pharm. 1890, 115), barbaloine (Barbadoes) and curagaloine (Curacao) are identical; whilst Tilden (Journ. Chem. Soc. 1872, 205; 1877, 264) considers barbaloine, socaloine, and zanalaine as probably identical.

THE author extracted Barbadoes aloes with acetone and glacial acetic acid, and from the residue extracted the aloine by methyl alcohol, some being also obtained from the acetone solution. After drying *in vacuo* over sulphuric acid, the analytical results accorded best with the formula of Groenwold,  $\text{C}_{16}\text{H}_{17}\text{O}_2 + \text{H}_2\text{O}$ . Barbaloine crystallises from water with  $3\frac{1}{2}\text{H}_2\text{O}$  in yellow needles. A dimethyl derivative was obtained. When barbaloine once re-crystallised from methyl alcohol is again allowed to separate from that solvent, the mother-liquors on concentration deposit yellow plates; these contain 14—15 per cent. of water and consist of a new aloine isomeric with barbaloine. The existence in the same aloes of these two isomers crystallising with 1 and 3 molecules of water, probably explains the differing content in water of crystallisation found by certain authors. Socaloine and zanalaine may be mixtures of these two aloines in varying proportions.

—A. C. W.

*Pilocarpine and Pilocarpidine, Isomerism of.* A. Petit and M. Polouovski. J. Pharm. Chim., 6 ser., 6, (1), 8.

FROM the results of their previous researches the authors have been led to the conclusion that pilocarpine and pilocarpidine are isomeric forms of the same body, and therefore to doubt that the transformation of pilocarpine into pilocarpidine is accompanied by the production of methylic alcohol, as stated by Hardy and Calmels and others (this Journal, 1887, 675). Further experiments confirm their views, and show that, although aqueous solution of caustic soda affects the transformation of pilocarpine into pilocarpidine, no trace of methylic alcohol is formed during the process, and therefore that there can be no elimination of a methyl group. It is found also that the hydrochloride of pilocarpine, if fused for a few minutes at  $200^\circ \text{C}$ ., is wholly transformed into pilocarpidine hydrochloride without any appreciable loss in weight. After this treatment the salt has all the physical and chemical properties of pilocarpidine, thus proving that pilocarpine is transformed into pilocarpidine without any chemical alteration, and that the change of characters is due entirely to molecular rearrangement, the nature of which has not been at present determined.—J. O. B.

*Pilocarpine and Pilocarpidine Chloroplatinates, Further Note on.* A. Petit and M. Polouovski. J. Pharm. Chim., 6 ser., 6, (1), 11.

THE following further particulars concerning the chloroplatinates of pilocarpine and pilocarpidine are given. Pilocarpine chloroplatinate occurs as a bright yellow precipitate, which crystallises from boiling water in large orange lamellae, readily soluble in boiling water, but only slightly so in cold water. In water at  $23^\circ \text{C}$ . the solubility is 0.8 in 100. The salt contains no water of crystallisation, and melts at  $213^\circ \text{C}$ .

Pilocarpidine chloroplatinate has the same crystalline form as the preceding salt, but is much less soluble in boiling water, and has just half the solubility in cold water, the figure for  $23^\circ \text{C}$ . being 0.4 in 100. It, too, is anhydrous. It melts between  $222^\circ \text{C}$ . and  $224^\circ \text{C}$ . The determination of the platinum gave precisely the same figures from both salts.

—J. O. B.

*"Loretin," m-Iodoxyhydroxyquinoline Sulphonic Acid, Notes on.* Ad. Claus and S. Baumann. J. für prakt. Chem. 55, 17.

THE authors combat the prevalent theory that loretin ( $\text{C}_9\text{H}_7\text{N}_3(\text{OH})_2\text{I}(\text{HSO}_3)$ ) and its combinations owe their germicidal action as surgical dressings to the liberation *in situ* of iodine in a nascent condition. No instance of the characteristic eruption produced by free iodine has been recorded during the whole period, extending over 15 years in which loretin has been employed, nor has iodine ever been detected in the urine of patients treated with it. The authors find that loretin compounds are quite stable, the dry salts always requiring to be heated to over  $200^\circ \text{C}$ . before decomposition sets in. The only instance in which free iodine is liberated at normal temperatures is when the aqueous solution is exposed to sunlight—a condition which never occurs in clinical practice. The only change which the loretin molecule appears to undergo in ordinary use would seem to be the combination of a molecule of water with the hydrogen atom, and the simultaneous production of hydrogen peroxide and hydriodic acid, the latter being immediately recombined; or it may be that the loretin molecule, as a whole, without undergoing decomposition, combines with septic matter and renders it harmless.

THE authors have prepared neutral and basic salts of calcium, strontium, barium, and magnesium, with loretin. The normal calcium salt prepared by precipitating a solution of a normal loretinate of an alkali with calcium chloride, forms a heavy orange crystalline precipitate, which, from its property of adhering to gauze or wool, renders it suitable for the preparation of antiseptic dressings.

By pouring an almost saturated alcoholic solution of calcium chloride on to the surface of a 1—1½ per cent. solution of sodium loretinate, and leaving them in contact, calcium loretinate crystallises out in fine red rhombic prisms,

which have trichroic properties. When heated, these lose their characteristic colour and become yellow. Basic calcium loretinate is obtained by treating a very dilute solution of basic alkaline loretinate with calcium chloride solution. The basic lime salt slowly forms cream-coloured needles.

The strontium salts closely resemble those of calcium, but the normal barium salt is much more soluble than either of them, and crystallises in red needles. Basic barium loretinate forms greenish-yellow needles. The normal salt of magnesium was unstable and very sensitive to sunlight; it crystallises in opaque, flat prisms. Basic magnesium loretinate was more easy to isolate, being more stable. It forms yellow prisms containing 5 mols. of water.

—J. O. B.

*Citronella, Commercial Oil of.* J. C. Umney and R. S. Swinton. Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1416], 138—139.

THE authors contradict the statement that the differences in specific gravity, optical activity, and other properties, between the oil of citronella derived from native sources in Ceylon, and that distilled by two English firms there, is due to adulteration with a wood oil. It was found that these differences are due to the presence in the oil distilled by the natives, of a sesquiterpene, to the amount of 37 per cent., which does not distil over in a current of steam like the products of the English firms, and which raises the specific gravity; and also of a highly active terpene which raises the optical rotation. The presence of these constituents reduces the odour value and impairs the solubility in alcohol.

—A. S.

*Petroleum, Medicinal. [Presence of Sulphur Compounds.]* F. C. J. Bird. Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1416], 153—154.

WHITE petroleum (sp. gr. about 0.885) can be obtained more free from taste and odour than the lighter oils, but most of the commercial oil, much of which is sold as chemically pure, contains a certain proportion of sulphur compounds, probably introduced during the process of bleaching. White petroleum jelly is frequently a mixture of ceresine and white oil, and contains the impurities of the latter. Very pale jellies, which are true non-crystalline petroleum residues, also usually contain sulphur due to the bleaching process. Yellow oils, though generally free from sulphur, are in many cases so tainted with a "paraffine" flavour as to be unfit for internal use. The yellow petroleum jellies are the purest as far as sulphur is concerned. It was found that, as far as could be traced with certainty, the Russian oils contained sulphur, whilst the American oils were free. The reduction test for sulphur with zinc and hydrochloric acid is recommended as convenient, easily applied, and delicate. 1 drm. of the sample, and 0.5 drm. of absolute alcohol, and 15 minims of pure hydrochloric acid are shaken in a test tube with a piece of pure zinc. The presence of sulphur is indicated by the brown or black coloration produced on a strip of paper, moistened with subacetate of lead, which is suspended in the upper part of the tube.—A. S.

*Hypophosphites.* C. T. Tyrer. Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1416], 150.

See under XXIII., page 764.

*Chloral Hydrate Reaction with Ammonium Sulphide.* J. Lesinsky and C. Gundlich. Amer. Chem. J. 19, 603.

See under XXIII., page 765.

*Digitalis, Determination of Active Principles of.* C. C. Keller. Ber. Deutsch. Pharm. Ges. 7, 125; through Pharm. J. 4, [1413], July 24, 1897, 62.

See under XXIII., page 767.

*Vanillin-Para-Phenetidine.* C. Goldschmidt. (Ger. Pat. 91,171.) Pharm. Centralh. 38, 333.

THE patentee obtains a combination of paraphenetidine with vanillin by heating the two bodies together to about 140° C. The constitution is stated to be—

When recrystallised from hot water it melts at 97° C. It is said to be hypnotic and anti-neuralgic as to action. It is also soluble in water.—J. O. B.

*Tetra-Iodo-Ethylene (Di-Iodoform), Preparation of.* Biltz. Ber. 1897, 30, [10], 1200; through Pharm. Zeit. 42, [52], 418.

TETRA-iodo-ETHYLENE, which has been recommended as an iodoform substitute on account of its freedom from odour, may be prepared as follows:—50 grains. of iodine are dissolved with heat in a saturated solution of iodide of potassium and the solution cooled to 0° C.; small pieces of coarsely powdered calcium carbide are now cautiously added, in small quantities at a time, the solution being kept well stirred. The reaction is represented by the equation—

Tetra-iodo-ethylene forms yellow non-volatile needles melting at 187°. It is less soluble than the accompanying di-iodo-acetylene, which occurs in colourless volatile needles, which are readily soluble in most solvents. The author states that di-iodo-acetylene is a powerful germicide, in which property it is only surpassed by the extremely poisonous cyanogen iodide. Tetra-iodo-ethylene has the same action on wounds as iodoform, but it is an odourless substance.—J. O. B.

*Iodoformin and Iodoethylformin, Preparation of.* Boequillon Limousin. Méd. nouv. 1897; through Pharm. Cent. 38, 457.

TRILLAT prepares iodoformin,  $C_6H_{12}N_4I_4$ , by first mixing together ammonia and formaldehyde in molecular proportions and then adding an alcoholic solution of iodine, or a solution of iodine in potassium iodide, to the solution of hexamethylene tetramine so formed. Iodoformin falls as a yellowish-brown crystalline pulverulent precipitate, which is collected, washed, and dried. It is insoluble in the cold in water, alcohol, ether, benzene, or chloroform; soluble in acetone, and sparingly dissolved by boiling alcohol. Boiling water decomposes it into iodine and formaldehyde, and it is decomposed in a similar manner by long standing at 40° C., with weak alkaline solutions. It contains 80 of iodine.

Iodo-ethylformin,  $C_6H_{12}N_4 \cdot (C_2H_5I)_2$ , is obtained by the action of ethyl iodide on a weak alcoholic solution of hexamethylene-tetramine. It crystallises in long, slender, colourless needles readily soluble in water, the solution being almost tasteless. It is sparingly soluble in alcohol, and insoluble in ether and in chloroform. Sodium carbonate decomposes it, with the formation of sodium iodide, a small quantity of ammonium carbonate, and formaldehyde. Strong acids also liberate formaldehyde from it. It has been prescribed for internal use by Bardet as a substitute for alkaline iodides.—J. O. B.

*Iodoform, Decomposition of, by Light.* G. Fleury. J. Pharm. Chim. 1897, 6, [3], 97.

THE author confirms the prevailing opinion that when solutions of iodoform are exposed to the action of light, decomposition, accompanied by the liberation of free iodine, only takes place up to a certain point. This he attributes to the fact that the reddish-brown solution of iodine so formed, prevents the passage of the ultra-violet rays, and so obviates further decomposition. It is found that when an ether-alcohol solution of iodoform, to which an excess of reduced silver is added, is placed in a white glass flask and exposed to sunlight, either direct or diffused, in the course of a few days practically the whole of the iodoform is decomposed, and the amount of silver iodide found approximates to the theoretical quantity of iodine contained in the iodoform. It is evident, therefore, that when the iodine liberated by the action of sunlight on iodoform is removed as it is formed, the decomposition is virtually complete.—J. O. B.

*Bitter Fennel, Oil of.* E. Tardy. J. Pharm. Chim. 1897, 6, [3], 98.

THE oil of cultivated bitter French fennel is found to contain: (1.) A dextro-rotatory terpene. (2.) Phellandre: e-

(3.) Cymene. (4.) Fenchone (termed by the author "fenone"). (5.) Estragol. (6.) Anethol. (7.) Anisic aldehyde. (8.) Anisic acetone. (9.) Anisic acid. (10.) An undetermined crystalline body having the empirical formula  $C_{15}H_{14}O_2$ , the constitution of which has not yet been ascertained.

The oil obtained from fennel cultivated at Grasse had a specific gravity at 0° C. of 1.007; the rotation index for the 100 mm. was  $\alpha_D + 18^\circ 20'$ . The anisic acid was removed by washing with aqueous potash, after which, on treatment with sodium bisulphite, the aldehydes and ketones were precipitated. These were set free by treating the purified precipitate with potash, and the oily liquid thus obtained was submitted to fractional distillation. The two chief fractions distilled between  $246^\circ$ — $250^\circ$  C. and  $260^\circ$ — $265^\circ$  C. The former was anisic aldehyde and the latter anisic acetone; on oxidation with permanganate in aqueous solution, this gave anisic and acetic acids. It appears to have the constitution  $C_6H_4(OCH_3)(CH_2COCH_3)$ . In fractionating these bodies a crystalline substance came over between  $270^\circ$ — $280^\circ$  and formed a butter-like mass, which, when recrystallised from chloroform, melted at  $213^\circ$  C. The author assigned to it the formula  $C_{15}H_{14}O_2$ . It is possible that it is a coumarin-like body, formed by the action of the anisic and acetic acids, liberated during distillation, on the aldehydes. The other bodies enumerated above were obtained from the residual oil, after treatment with bisulphite, and were separated from each other by fractional distillation, and identified by their specific reactions.—J. O. B.

*Certain Arums, Active Principles of.* A. Hébert and F. Heim. *Comptes Rend.* **124**, 1368.

THE plants examined were *Arum maculatum*, *A. italicum*, and *Arisarum vulgare*. In all, the active principles were found to be in very small quantity. They consisted of—

(A.) An *alkaloid* obtained in the proportion of 0.005 per mille. This was isolated in the form of a brown oily volatile liquid having an odour of mice, strongly alkaline in reaction, and fuming when approached by the stopper of a hydrochloric acid bottle. In chemical and physical properties it closely resembled cocaine; it differed from that alkaloid, however, in its physiological potency, the effects produced on the living organism being similar to those of cocaine, but less intense. It is, however, an active poison: 100 kilos. of the fresh plants yielded from 4 to 5 grms. of this body.

(B.) A *saponin*, found in the greatest quantity in the resting tubers, where it amounted to 1 per mille, although it was detected in small quantities in all parts of the plant. The toxic action of this saponin is said to be less marked than that of other sapotoxins. When hydrolysed, it gave glucose and a sapogenin.

The authors were unable to obtain any evidence of the presence of hydrocyanic acid, which has been reported by Jorissen to be present in these plants.—J. O. B.

*Oil of Turpentine [French], Detection of Rosin Oil in.* A. Aignan. *Comptes Rend.* **124**, 1367.

See under XXIII., page 764.

## PATENTS.

*Piperazine and Polybasic Acids, The Manufacture of Acid Salts of, and the Production therefrom of Double Salts of Lithia and Piperazine.* A. Koelliker, Benel-on-Rhône, Germany. Eng. Pat. 18,981, Aug. 27, 1896.

PIPERAZINE forms acid salts with oxalic, tartaric, and citric acids; these acid salts form neutral double salts with lithium. The compounds mentioned, are claimed as new and useful products.—A. C. W.

*Vinylidiacetonalkamine, The Production of a, and of Anesthetics therefrom.* Chemische Fabrik auf Aktien vorm. E. Schering, Berlin, Germany. Eng. Pat. 29,697, Sept. 18, 1896.

THE vinylidiacetonalkamine of Fischer (Ber. **17**, 1794) is a mixture of two bases, melting at  $138^\circ$  and  $161^\circ$ — $162^\circ$ ; these

may be separated by crystallisation of their salts or the bases themselves. The former alkamine is claimed as a new product, together with its derivatives.—A. C. W.

*Vanillin, Impts. in the Manufacture of.* La Société Chimique des Usines du Rhône, Lyons, France. Eng. Pat. 21,106, Sept. 23, 1896.

THE separation of vanillin from mixtures with *m*-methoxysalicylic aldehyde, by treatment with calcium hydroxide (or other hydroxides) in solution or suspension, is claimed. On agitation, vanillin dissolves in the alkaline solution; the isomer is precipitated as calcium salt. The two compounds are recovered by acidifying, and extracting with ether.

—A. C. W.

*Iron for Medicinal Purposes, The Manufacture of Improved Preparations of.* E. Dolle, Bremen, Germany. Eng. Pat. 9701, April 15, 1897.

THE manufacture of iron preparations which do not possess the unpleasant flavour of iron, by precipitating chloride of iron with phosphate of soda and combining the precipitate with one or more of certain essences and finetures (cardamon, orange, vanilla, &c.), is claimed.—A. C. W.

*Hydroxylated Ethers of Phenol [Guaiacol, &c.], Process for the Extraction of, from Mixtures.* L. Lederer, Munich, Germany. Eng. Pat. 12,964, May 25, 1897.

THE hydroxyphenol ethers form crystalline compounds with potassium carbonate; these are permanent in air, but partly decomposed by water, the presence of potassium carbonate preventing the decomposition. They are soluble in hot alcohol and benzene, and crystallise out on cooling. The patent claims the use of this property for the extraction of such ethers from mixtures, by treatment with potassium carbonate or its solution, or by treatment of solutions of the potassium phenolates with carbonic acid. The potassium carbonate compound is precipitated from aqueous solution by ether, and decomposed by acids.

—A. C. W.

*Phenetidine-sulphonic Acid and its Salts, as also of Acetyl Derivatives of the latter [Antipyretics], Manufacture of.* F. Hoffmann, La Roche and Co., Basle, Switzerland. Eng. Pat. 14,375, June 14, 1897.

THE process for the production of the phenetidine-sulphonic acid, which consists in the treatment of phenetidine with concentrated or fuming sulphuric acid, and purification by conversion into salts, and precipitation of the acid by the addition of mineral acid, the production of the salts by neutralisation or double decomposition, of the acetyl derivatives by heating these salts with acetic acid or anhydride, and finally the acid, its salts, and their acetyl derivatives as new compounds, are claimed. The acetyl derivatives are antipyretics easily soluble in water.

—A. C. W.

*Theobromine, Impts. in the Manufacture or Preparation of.* C. F. Boehringer and Soehne, Mannheim, Germany. Eng. Pat. 14,610, June 16, 1897.

IN this patent the manufacture of theobromine is claimed "by transforming 3,7-dimethyl-6-amino-2,8-dioxypurine, by treatment with phosphorus oxychloride, into 3,7-dimethyl-6-amino-2-oxy-8-chloropurine, reducing the latter to 3,7-dimethyl-6-amino-2-oxy-8-purine, and then by treatment with nitrous acid, converting it into theobromine."—A. C. W.

*Trichloropurine, A Process for the Production of.* C. F. Boehringer and Soehne, Mannheim, Germany. Eng. Pat. 14,612, June 16, 1897.

THE process consists in heating 2,6-dichloro-8-oxy-8-purine with phosphorus oxychloride.—A. C. W.

*Isoeugenol and Derivatives thereof [for preparing Vanillin], Impts. in the Manufacture or Preparation of.* C. F. Boehringer and Soehne, Mannheim, Germany. Eng. Pat. 14,611, June 16, 1897.

THE patent claims "converting eugenol into isoeugenol in such a way that the free hydroxyl group of the eugenol is

protected by the introduction of the phosphoric acid radicle," and modifications of this process in which eugenol is converted into eugenol phosphoric acid by the action of phosphorus oxychloride, and the latter heated with alcoholic potash, or heated with aqueous alkali, which transforms it into isoeugenol phosphoric acid, this being converted into isoeugenol by the action of heat on the acid salt of an alkali metal.—A. C. W.

*Sweetening Substance [Methylbenzene Sulphonic Imide].*

*A New or Improved, and a Process for its Manufacture.*

E. R. Savigny, London. Eng. Pat. 4467, Feb. 19, 1897.

METHYLBENZENE SULPHIMIDE is claimed as a new sweetening substance, and the process for its manufacture, which consists in saponifying toluene cyanosulphamide with "dry potash," precipitating the methyl benzene sulphonic imide by the addition of sulphuric acid, and recrystallisation from xylene, after which it is finally obtained in a pure form by the addition of dimethylbenzene.—A. C. W.

[*Saccharine.*] *o-Anhydrosulphamine-benzoic Acid from p-Sulphamine-benzoic Acid, Process for Separating.*

R. Barge, Stassfurt, Germany. Eng. Pat. 15,009, June 21, 1897.

THE inventor claims the processes for the separation of the two sulphamine-benzoic acids, which consist in precipitating a basic copper salt of the para compound from a solution of the neutral salts of both, and in precipitating the copper salts together and dissolving out the *o*-sulphamine-benzoic acid by sodium hydroxide or carbonate. In the first case sufficient caustic soda may be added before precipitation to neutralise the free acid formed.—A. C. W.

## XXI.—PHOTOGRAPHY.

*Commercial Egg Albumin, Estimation of.* P. Carles.

J. Pharm. Chim. 1897, 6, [3], 102.

See under XXIII., page 767.

### PATENTS.

*Chromo-Photography, Impts. in and relating to.* — Valentin Vaucamps, Paris. Eng. Pat. 20,898, Sept. 21, 1896.

FILMS are made by superposing sensitised layers tinted differently—in the order of the colours of the spectrum if for photography in natural colours—in any other order if for fancy pictures. One such layer is partially set by artificial cooling before the next is poured on, perfect adhesion without sensible mixture being thus secured. Such a film is exposed under a negative, red side next the negative, and, when developed, the layers are eaten away to different depths, the red being left insoluble under the light parts of the negative, while the blue layer only is affected (and hence laid bare by the removal of the superposed red and yellow by the developing solution) under the dark parts. When fixed, a picture in natural colours, visible by reflected light only, however, is obtained. To procure a picture visible by transmitted light, the fixed film (on paper) is transferred to a perfectly plane glass plate, red side downwards. The result of this is, so to speak, to transfer the reliefs from the front to the back of the film, and by grinding down these reliefs till the film is of uniform one-layer thickness, we get a picture showing by transmission the same colours which the untouched film showed by reflexion. Pictures can be mechanically multiplied by placing the finished fixed film and a similarly prepared but unsensitised film in a reproducing machine, similar to that used for musket stocks or similarly shaped pieces of woodwork.

—J. T. D.

*Dishes or Baths employed in Developing and like Photographic and Chemical Operations.* W. S. Wain. Ripley, Derbyshire. Eng. Pat. 21,495, Sept. 29, 1896.

AN ordinary developing dish with a broad, flat bar crossing the middle of its under side, on which the dish rests. The width of this bar is so arranged that when the dish and its contents are tilted, the centre of gravity is just beyond the bar, towards the raised end. Under these circumstances,

when let go, the dish rocks backwards and forwards for a while, and ultimately comes to rest in a horizontal position. Instead of the broad bar, two parallel narrow ribs (corresponding with the edges of the bar), or two short webs (corresponding with the ends of the bar), or four points (corresponding with the corners of the bar) may be used.

—J. T. D.

*Sensitised Photographic Plates and Films, Impts. in.* M. Levy, Berlin. Eng. Pat. 10,098, April 22, 1897.

THIS glass or celluloid plates are coated on both sides with a sensitised film. Several of these, if thin enough, may be used superposed. The time of exposure is thus shortened. Though intended originally for photographing by X-rays, the device may be used for ordinary photography.—J. T. D.

*Sensitive Plate or Film, A New, and a Method of Producing, Developing, Fixing, and Toning the same.* T. C. Porter, Eton. Eng. Pat. 12,922, May 25, 1897.

A GELATIN or other film is immersed in solution of ferric ammonium citrate or other ferric salt for three minutes, and is then thoroughly and rapidly washed. After drying, the film is exposed under a negative, developed by potassium ferriyanide, and fixed by hydrochloric acid. The positive is then treated with very dilute ammonia solution till the greenish-blue tint has acquired a sufficient violet tinge. The pictures so obtained, are suitable for lantern slides exhibiting ice and snow scenery, sea-views, &c.—J. T. D.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Annual Report, for the Year 1896, of H.M. Inspectors of Explosives.*

THE inspectors have, happily, to chronicle only one death due to fire or explosion during manufacture.

Note is made of the continued growth of the trade in explosives, the number of factories increases—five having been licensed during the year, and several existing ones have increased their area.

In regard to the importation of nitroglycerin compounds 1,259,200 lb. were received in 1896, against 880,070 in 1895, and this amount is greater than during any previous year, with the exception of 1889, when 1,325,950 lb. were imported. The quantity of dynamite, which fell to 23,000 lb. in 1894, but then revived to 56,000 lb. in 1895, has further risen to more than three times that amount in 1896. There has been a large increase in the importation of carbonite, and it now heads the list of imported nitroglycerin explosives.

Of detonators, 9,780,000 were imported, showing that a great percentage of this trade still remains in foreign hands. There are, however, six factories in this country in which detonators are made.

While collodion cotton now appears on the list of authorised explosives, it is exempt from the conditions imposed on explosives "when it is in solution in alcohol and ether, or wet, or saturated with methylated spirit and enclosed in air-tight cases." With regard to the particular form of collodion cotton which is used in the manufacture of xylonite and kindred articles, certain relaxations in the conditions of manufacture have been granted when the collodion cotton contains not more than 11·11 per cent. of nitrogen.

Dr. Dupré's report is given in full, as usual, and in it he says that "the extremely high character shown last year among explosives proper has, however, unfortunately, not been maintained." Fourteen samples, of which 10 were gelatin dynamite No. 2, were rejected, against none in the preceding year. He also notes a falling off in the activity of inventors, as only five new explosives were submitted for approval.

Attention is again called to the danger as well as illegality of using chlorate and sulphur in coloured fires, and even of using sulphur and strontium nitrate—instances of such a mixture taking fire spontaneously having been recorded.

An explosion of ammonium nitrate due to overheating in the course of the manufacture of nitrous oxide (laughing-gas) took place in Kensington, and Dr. Dupré considers it

worthy of note "in connection with the often reiterated assertions of some manufacturers that certain explosives containing ammonium nitrate cannot be exploded by heat or fire."

An interesting accident, unattended with loss of life or personal injury, occurred at the Arklow Factory during the nitration of a charge of glycerin. When there were about 60 lb. of nitroglycerin formed, the charge fumed off, and although the connections to the drowning tank were immediately opened, it was subsequently ascertained that no nitroglycerin was among the water and acids in the drowning tank; consequently the whole of the estimated charge of nitroglycerin (60 lb.) must have fumed off in a few seconds. The cause of the accident was attributed to a small leak subsequently discovered in one of the cooling coils.

A destructive fire occurred in March at the Cotton Powder Works near Faversham, and several interesting points were noted: one, "that some 5,000 to 6,000 lb. of gun-cotton in water, which were exposed to the full effect of the fire, were practically unharmed, although in some cases the vats and vessels containing it were burnt away; and an even more interesting and important fact was the burning away inexplosively of over 3,000 lb. of gun-cotton (containing about 30 per cent. of water) made for the War Office and contained in barrels of 27½ lb. each."

Short accounts are given of the principal accidents and outrages which occurred at home and abroad; also of the more important explosions and fires due to petroleum; and, in the latter connection, accidents are described which took place when the inside of tanks were being painted with a solution of coal-tar in crude low-flashing tar oil. Such substance ought to have been labelled "highly inflammable."

Attention is drawn to the Order, in virtue of which, after January 1, 1897, it will be unlawful to use in certain parts of coal mines any explosive other than a "permitted explosive," a list of which is given. "It is proposed to establish a Government testing station at Woolwich, at which, from time to time, explosives which may be submitted for addition to the 'permitted list,' or modifications of explosives already on that list, can be tested as to their non-liability to ignite inflammable gas or coal-dust, or admixtures of the two, and their suitability and safety for use in coal mines."—W. M.

#### PATENTS.

*Explosives, Impts. relating to the Manufacture of.* G. Kynoch and Co., and A. T. Cocking, both of Witton, Warwick. Eng. Pat. 22,190, Oct. 6, 1896.

This invention relates to an apparatus for drying cordite and the effectual recovery of the solvent employed in its manufacture. The cordite is spread on metallic and perforated removable trays, which rest on ledges in metallic connection with the walls of the vacuum drying chamber, consisting of a cylindrical cast-iron vessel surrounded by a water-jacket, the latter being heated to any desired temperature. "The acetone or other solvent vapour is driven off by the heat transmitted by conduction from the hot-water jacket and the vapour is drawn away from the vacuum chamber into a condenser." The air escaping from the condensing plant may be conveyed through a water-scrubber. Drawings accompany the specification.—W. M.

*Matches, A Non-Ignitable Coating applied to Common Lucifer Match Boxes and Finger Ends of.* L. A. Thomas, Yarm-on-Tees, Yorksh'ire. Eng. Pat. 24,846, Nov. 6, 1896.

The inventor proposes to reduce "the danger from fire in storage or carriage of lucifer matches," by treating the matches and the containing boxes and wrappers with a solution of silicate of soda.—W. M.

*Explosives, Impts. in the Manufacture of.* F. Volpert, Dortmund, Germany. Eng. Pat. 14,196, June 10, 1897.

The inventor claims increased safety for explosives used in coal mines by the addition

to them of "sulphur, pyrosulphur, polysulphur, and polythionic acid salts as well as analogous acids of silicium, phosphor, selenium, tellurium, and antimony, including meta-acids, also the salts of barium, wolfram, molybdenum and tin acids." "The simultaneous use of the cyanogen compounds is also to be recommended."—W. M.

*Nitrocellulose, Impts. in the Manufacture of.* A. Liedbeck, Stockholm, Sweden. Eng. Pat. 14,690, June 17, 1897.

The inventor obviates the disadvantage of want of uniformity in the product resulting from the ordinary method of nitrating poor qualities of cellulose, by allowing the beating and nitration to proceed simultaneously. "The acid mixture is introduced into the beater, which is then set in motion, the cellulose being introduced by degrees through a feeding aperture in the hood until the whole quantity weighed off has been fed in."

When the mass has acquired the fineness desired, it is freed from excess of acid centrifugally, and then washed.—W. M.

*Matches, Impts. in.* J. T. Maguire, Waterloo, Liverpool. From Diamond Match Co., Chicago. Eng. Pat. 14,989, June 21, 1897.

The object of this invention is to render the match shank unflammable by means of sulphate of ammonia or other suitable salt.—W. M.

*Explosive Compounds, Impts. in the Manufacture of.* Hudson Maxim, Surrey. Eng. Pat. 15,499, June 29, 1897.

The object of this invention is to overcome the great difficulty experienced with pyroxylin explosives, for use in "guns of large calibre on account of the density of a colloid of gun-cotton and the small extent to which the flame of combustion will consume the explosive material under admissible pressure and during the very short time that elapses before the projectile leaves the gun." To attain this object the inventor makes a paper or paper board of trinitrocellulose, which is then sized or impregnated with a size consisting preferably of dinitrocellulose, but may be dinitrocellulose and nitroglycerin, or other suitable material, dissolved in a solvent which is not a solvent of trinitrocellulose. Larger masses of the explosive can be made by pressing several sheets together, the formed sheet being then multi-perforated and freed from solvent. "To confine more exclusively the combustion to, and within, the perforations, and thereby secure the maximum of increase of burning area as the powder becomes consumed," the external surfaces of the powder are coated with a material of a "less combustible character than the main body."—W. M.

### XXIII.—ANALYTICAL CHEMISTRY.

#### APPARATUS, ETC.

*Sulphur in Coal-Gas, &c., Apparatus for the Estimation of.* F. Fischer. Zeits. angew. Chem., 1897, [10], 302—303.

This apparatus has the advantage that it does not require any arrangement for the continuous introduction of an

absorbing agent for the sulphur compounds evolved, and it is also suitable for the determination of sulphur in burning oils, &c. The gas is burnt within A at the rate of 25 or 30 litres (1 cub. ft.) per hour, and the current of air is regulated so that the gases issuing at *o* still contain 4 or 6 per cent. of oxygen. During the combustion of 50 litres, some 50 c.c. of weak sulphurous and sulphuric acid condense in the bulbs *e* and gradually run out through *c* into a small beaker placed underneath, protected from the heat of the flame *g* by the asbestos sheet *a*. The condensed liquid is either titrated direct, or after oxidation with hydrogen peroxide by means of decinormal alkali; or for greater security, 20 c.c. of the standard soda are introduced into the bulbs through *o* before beginning the test. The sulphuric acid may also be estimated gravimetrically. The joint at *u* consists of an asbestos ring, or the whole apparatus may be constructed in one piece.—F. H. L.

**Mercury Pump, A New: Without Taps and Movable Joints.** H. Henriet. *Comptes Rend.* 1897, **125**, 22—23.

In this pump, the lower extremity of the working bulb is connected by a descending tube, partly of glass, partly of rubber, to a mercury reservoir, which latter can be raised or lowered by a chain and pulley in the usual way. The tube just below the working bulb, is branched. The branch ascends vertically for some distance, is bulbous at the top, then again descends, and is finally bent slightly upwards, terminating in a horizontal portion, to which the vessel to be exhausted is attached. At the lower bend, connection is made with a doubly branched tube, both limbs of which descend and terminate in a trough of mercury. One of these limbs is graduated and serves as a pressure gauge, as also for the introduction of gas into the pump and attached vessels. By means of the second, which terminates in a length of rubber tube, connection may be made with an auxiliary water-pump. Returning to the working bulb—its upper portion is drawn out to a capillary tube, which is bent downwards and terminating in a mercury trough forms the outlet of the pump. In operation, the mercury flowing out of the working bulb, presently uncovers the branch tube leading to the exhaust; subsequently, when the mercury is caused to re-ascend, the gas that has passed into the bulb is expelled through the upper capillary tube.

—H. T. P.

**Hand-Jigger, An Experimental.** P. W. Duffield. *Eng. and Mining J.* 1897, **64**, 68, from the *Inst. of Mining and Met.*

In the concentration of ores, the estimates made by means of hand tests on the finely ground material are sometimes unsatisfactory, and the author suggests the use of a hand-jigger, in which quite small quantities of ore can be treated and their behaviour during the process actually observed. The concentrates cannot by means of such a machine as that described, be automatically discharged in the form of a finished product, but any ore which is coarser than the screen used, can be subjected to the pulsating action communicated to the water by a plunger, and the result observed from time to time by employing a glass tube in the ore compartment. A screen as fine as 80 mesh can be used in this jigger with advantage and it is provided with an adjustable stroke, the speed being subject to the will of the operator. Although clean material is not actually delivered apart from the gangue, the separation is so indicated that some estimate can be formed of the duty which might be expected from actual working on a large scale.—A. S.

**Phosphates and Platinum.** W. G. Stratton. *Brit. Pharm. Conference*, Aug. 1897. *Pharm. J.* 1897, [1416], 157.

THE author calls attention to the fact that when phosphates are heated in a platinum vessel in the presence of carbon, a marked erosion and eventually an absolute fusion of the metal may result.—A. S.

**Ampère-Meter, Thermal.** C. Camichel. *Comptes Rend.* 1897, **125**, 20—21.

THE apparatus comprises a delicate thermometer, the bulb of which is surrounded by a slightly wider tube of glass, the annular space between the two being filled with

mercury, and the whole suitably screened from air currents. The current to be measured is passed through the mercury jacket for 30 seconds and the elevation of temperature noted. The apparatus is calibrated by comparison with a standard ampère-meter. Its scale is open and regular; and according to the author, the increase of temperature corresponding to a given current remains constant when the initial temperature ranges from 15°—28° C. The instrument is not liable to get out of order, and is especially suitable for checking the indications of the ampère-meters in distributing stations. In a voltmeter, constructed on the same principle, the dilatation of a column of mercury of high resistance is measured.—H. T. P.

**Apparatus for Purifying Gases.** New. A. J. J. Vandeveldt. *Chem. Zeit.* **21** [44], 445.

This apparatus has been devised to obviate the inconveniences attending the ordinary forms, due to the high resistance offered to the gases and the necessity for the frequent renewal of the sulphuric acid, &c. employed in drying.

A 2-litre Woulff's bottle A is fitted with a tube *b*, containing soda lime, and is then packed with solid potash covered with a layer of unslaked lime. The gas, after passing through a small preliminary dryer A' (a Woulff's bottle containing sulphuric acid), enters A through the hollow stopper *a* and diffuses through the contents, being

thereby freed from carbon dioxide. Issuing through *b*, and traversing the tube *c*, the gas enters the drying vessel B, filled with clean, dry, broken glass and concentrated sulphuric acid (the latter introduced through the hollow stopper *d*, with rose jet attached), where it is dried, and leaves the apparatus *via* the tube *c*.

The advantages of this arrangement are that the bulk of the moisture is removed in A', and thus the contents of A will remain in working order longer, especially since the mouth of *b* is not obstructed by incrustations. In addition to this, A is conveniently arranged for re-filling, as is also B, the spent acid from which can be drawn off through a tap *f* at the base, and replaced by a fresh charge through the funnel tube *d*. This should be done each time the apparatus is used.—C. S.

*caustic Potash and Soda, Commercial, Purified by Alcohol.* [Analysis.] E. Wurmman. Zeits. Anal. Chem. 36, 379.

See under VII., page 757.

## INORGANIC CHEMISTRY.—QUALITATIVE.

*Disulphuric Acid, Colour Reaction for.* E. Barral. J. Pharm. Chim. 1897, 6, (3), 104.

POWDERED para-dichloride of hexachlorobenzene,  $C_6Cl_6Cl_2$  (1:4), gives a magnificent reddish-violet coloration when dissolved in sulphuric acid containing disulphuric acid. On the addition of water or on exposure to the air, this colour slowly disappears as the disulphuric acid is converted into ordinary sulphuric acid. The colour thus produced is not due to impurities in the acid, since it is obtained by exposing a mixture of  $C_6Cl_6$  and pure synthetic  $SO_3$  to the action of moist air.

The reaction may be employed for the volumetric determination of disulphuric acid. To a known quantity of Nordhausen acid, a little of the powdered  $C_6Cl_6$  is added, and the mixture titrated with ordinary sulphuric acid containing one-tenth its weight of water, until the coloration disappears. In discoloured Nordhausen acid the end of the reaction is somewhat difficult to perceive, otherwise the process works extremely well.—J. O. B.

## INORGANIC CHEMISTRY.—QUANTITATIVE.

*Water Analysis, Applicability of Ammonium Carbonate in.* A. Rössing. Zeits. Anal. Chem. 36, 359—369.

It is asserted to be better, after evaporating a water and igniting the residue, to re-convert any calcium oxide formed from carbonate, by using water containing carbonic acid instead of by means of ammonium carbonate, as alkali chlorides are partly changed by the latter into carbonates.

The author evaporated 25 c.c. of solutions of sodium chloride and potassium chloride, containing 5 grms. per litre, to dryness, moistened with ammonium carbonate, dried, ignited and weighed, and found no loss in the residue even on repeating the treatment. A solution of sodium sulphate also suffered no loss.

A solution of calcium sulphate prepared from gypsum and containing per 100 c.c., sulphate corresponding to 0.1304 gm. of  $SO_3$ , after repeated evaporation with ammonium carbonate, drying and igniting gently, then contained sulphate equal to 0.01235  $SO_3$ , the residue weighing 0.167 gm. instead of 0.220, indicating a considerable loss of sulphuric acid by volatilisation. Magnesium sulphate also showed considerable loss, and the residue dissolved in hydrochloric acid with effervescence.

A mineral water was prepared containing calcium bicarbonate, calcium and magnesium sulphates and sodium chloride. The residue obtained on evaporation was very gently ignited and then moistened, in one case with ammonium carbonate and in the other with water through which a stream of carbonic acid had been passed, dried on the water-bath and again gently ignited. The residue treated with ammonium carbonate had diminished in weight, while that treated with water containing carbonic acid remained constant.

It was also found that using water containing carbonic acid when magnesium carbonate was present, or using sodium carbonate in the presence of magnesium chloride, avoiding ammonium carbonate and keeping the temperature low, enabled the operator to obtain fairly constant results. The magnesium carbonate obtained, contained 25 per cent. of  $CO_2$ ; it was therefore a basic carbonate, and the result is low from loss of carbonic acid. The addition of a definite quantity of potassium sulphate in the presence of magnesium chloride, as proposed by Tillmann, appears a much better method, the double salt  $MgSO_4 \cdot K_2SO_4$  being formed and potassium chloride.

The addition of dilute sulphuric acid, recommended by Fresenius, to determine the mineral salts in the form of sulphates cannot give exact results in the possible presence

of calcium and magnesium salts, since to convert the alkali bisulphates formed, ammonium carbonate must be used. Although the ammonium carbonate is added in the solid form and not in solution, it is found to cause loss of sulphuric acid, but the error in this case is small, and may be neglected in water analysis. The use of solid ammonium carbonate instead of water containing carbonic acid is, however, not advisable, as calcium oxide formed by ignition in the deeper layers of the residue may fail to be reconverted into carbonate.—L. J. de W.

[*Silicates, Analysis of.*] *Separation of Soluble Active Silica from Quartz.* G. Lange and C. Millberg. Zeits. angew. Chem. 1897, 393 and 425.

IN view of Michaëlis's statements to the effect that a solution containing 10 per cent. of  $Na_2O$  does not act upon quartz, even during several hours' boiling (this Journal 1895, 1065), and that soluble silica cannot be completely dissolved in sodium carbonate, the authors have submitted a large number of different varieties of silica to a lengthy investigation, the results of which are indicated below. Caustic alkalis cannot safely be employed to separate quartz from soluble silica as they dissolve too much of the former. Hot alkali carbonates can only be used with perfect accuracy after the powder under treatment has been freed from the most finely-divided portions by levigation, for if any appreciable amount of impalpable dust be present, some quartz is rapidly dissolved, even by 5 per cent. sodium carbonate on heating to the temperature of the water-bath; but assuming the material to have been prepared by the ordinary process of grinding, followed by shaking through the finest canvas, the error will probably not exceed 0.1 per cent. or 0.2 per cent.—the soluble silica being returned too high. All danger of the particles of the quartz itself penetrating the paper towards the end of the filtration may be avoided by the use of "hardened" papers, coupled with the saturation of the liquid and wash water, with common salt.

The diminution in the power of quartz to resist attack by caustic and even carbonated alkalis when it has been reduced to a truly impalpable powder, is far greater than has previously been recognised; and it is a matter of considerable interest, especially in the case of cement, to accentuate the importance of thorough grinding in order that the chemical properties of the crystalline silica may be fully utilised. Trass and puzzolana do not contain any free amorphous silica; but their active constituents consist of zeolitic silicates, the most notable one being a compound of sodium and aluminium resembling analcite, which is entirely soluble in 30 per cent. caustic potash on the water-bath.

It accordingly follows from the foregoing observations, that in the analysis of silicates, if the sample be reduced to the finest possible powder, treated with hydrochloric acid, and dried at  $110^\circ C.$ , the silica derived from the silicates decomposed by the acid may be readily separated from the quartz and the unattacked silicates, by digestion for 15 minutes with 5 per cent. sodium carbonate, the error not exceeding +0.2 per cent.—F. H. L.

*Nitric Acid, Quantitative Determination of, by Electrolysis.* K. Ulsch. Zeits. für Elektrochem. 1897, 3, 546—547.

IF a dilute solution of nitric acid or a solution of a nitrate in water be electrolysed with platinum electrodes in presence of sulphuric acid, and of a sufficiency of copper sulphate, the nitric acid is reduced completely to ammonia, and copper is deposited at the cathode. This reduction has been made the basis of a quantitative method by G. Vortmann. Some years ago, the author published details of a similar method, in which an iron-copper couple was used in a sulphuric acid solution to reduce the nitric acid, and the volume of gas liberated gave the data for the quantitative determination.

The author has recently experimented with a modification of Vortmann's method, in which a platinum plate covered with spongy copper is used as cathode, and no copper sulphate is used in the cell. Such cathodes, however, quickly lose their reducing power. Further experiments showed that the physical characteristics of the surface of the copper

cathode determined its reducing action, and led to the adoption of the following method:—A cylindrical spiral of copper wire (1.4 mm. diameter) is made by winding 2 metres in length of the wire, upon a glass tube of 15 mm. diameter. One end of the wire is bent into the line of the cylinder axis, and is left projecting about 15 cm., to serve as the conducting end outside the cell. The spiral is gently stretched until it measures 70 mm. in length. A straight platinum wire, 1 mm. thick and 20 cm. in length, is used as anode. A test tube 20 mm. wide by 17 cm. long is used as the electrolytic cell, and is closed by a rubber stopper, through which both anode and cathode ends pass.

The anode hangs in the centre of the spiral, and both must nearly touch the bottom of the tube. Before each determination, the copper spiral is heated in a Bunsen flame, to faint redness, and is immediately quenched in cold water. The solution used for the author's experiments contained a known amount of potassium nitrate; 20 c.c. were used for each test. This volume contained in each case 10 c.c. of normal sulphuric acid. Two accumulators coupled in series, gave the E.M.F. (4 volts) demanded.

The current density was reduced to 1.47 by means of a resistance; the surface of cathode immersed, was calculated from the known dimensions of the wire and spiral. The reducing action of a copper spiral cathode, prepared by heating as described, is so perfect, that for long no hydrogen bubbles are visible; and in a special experiment it was proved that 90 per cent. of the nitric acid had been reduced before bubbles appeared. The heat of the reduction causes the solution to gain in temperature. This is favourable to the reaction. The electrolysis must be continued for 10 minutes after the moment when hydrogen bubbles first become visible at the cathode. The ammonia produced is determined by titrating the solution for the excess acidity, and by calculating the ammonia equivalent to the loss of acid found.

The author gives a table, showing that in ten experiments conducted under proper conditions as regards excess of sulphuric acid, the average variation from the correct result was only .029 per cent., and the average time required for the electrolysis was only 36 minutes. The method therefore excels all others in speed and accuracy. Unfortunately the presence of other salts, e.g., chlorides, though as mere impurities, in the solution renders the results untrustworthy; and the use of this method is therefore confined to those cases where pure solutions are under examination.

—J. B. C. K.

*Iron Ores, Notes on the Determination of Insoluble Phosphorus in.* C. T. Mixer and H. W. Du Bois. Franklin Inst., 1897, 144, 137—138.

THE usual method of determining the phosphorus in the insoluble residue from an iron ore, by fusion with sodium carbonate is impracticable where many analyses are to be made. Hydrofluoric acid treatment led to no saving in time, and the heating to redness with sodium carbonate, although successful with low silica ores, was useless with those containing much silica, on account of the fusion of the mass. Ignition at a red heat with calcined magnesias extracted all the phosphorus, but simple calcination without any basic addition was equally successful. In the end, the simplest method found to be quite accurate, was as follows:—1.5 gm. of ore is dissolved in 25 c.c. of HCl (sp. gr. = 1.1), and the solution is evaporated to a syrup. After dilution, it is filtered into an Erlenmeyer flask, and the filter with the residue is ignited in a platinum crucible. The residue is then broken up with a platinum rod, and ignited for several minutes at a red heat, removed, cooled, and boiled in a beaker for 5 minutes with water containing a few drops of hydrochloric or nitric acid. After filtering, the solution is neutralised with ammonia and precipitated as phospho-molybdate, the precipitate being titrated by Handy's modification of the sodium hydroxide method. The solution from the insoluble residue, may be mixed with that containing the soluble phosphorus prior to precipitation, but it is better to treat the two separately.—W. G. M.

*Metals, Electrolytic Methods of Analysis of.* L. Wolman. Zeits. für Elektrochem., 1897, 3, 537—545.

The results may be summarised as follows:—

**Pure Solutions.**—The determination of copper in acid or ammonium oxalate solution, of lead as peroxide in nitric acid solution, and of silver in potassium cyanide or nitric acid solution, can be carried out with both speed and accuracy, and in these respects the electrolytic methods are quite equal to the purely chemical methods.

As regards iron and manganese, the electrolytic methods are far behind the chemical methods, especially in respect to the time demanded.

**Mixtures.**—The separation of two or more metals is possible in those cases where the one metal is not deposited in acid solutions. This method gives most satisfactory results in the case of solutions containing zinc and copper, nickel and copper, and cadmium with zinc.

The separation of zinc and nickel by Vortmann's method, which consists in using an alkaline sodium-potassium tartrate solution offers great advantages as regards speed, but the method leads at present to inaccurate results.

The separation of lead as lead peroxide at the anode in solutions made strongly acid with nitric acid, from zinc, silver or copper is complete. The deposition of the other metals on the cathode, in such strongly acid solutions is however too slow to be satisfactory, and in the case of silver the deposit is spongy. It is suggested by the author that this difficulty may be met by dissolving the cathode deposit, after all the lead is separated at the anode, removing the excess of acid by evaporation, and by then repeating the electrolysis with this less strongly acid solution, for separation of the zinc, silver, or copper.

In such cases, however, it may probably be quicker to separate the metals by chemical methods, and to use the electrolytic deposition only for their final separation from pure solutions.—J. B. C. K.

*Bronze and Brass, Analysis by Electro-chemical Methods.* A. Hollar. Comptes Rend. 1897, 124, [25], 1451—1453.

**Bronze.—Determination of Copper.**—Attack 50 grms. with 25 c.c. of nitric acid of specific gravity 1.32 (36° B.) and 15 c.c. of strong sulphuric acid, as described in a former paper (this Journal, 1897, 66). Dilute to 350 c.c., heat nearly to boiling, keep at this temperature till any deposit of tin clots and leaves a perfectly clear solution, then immerse the cone and spiral, and electrolyse as directed (*loc. cit.*).

**Determination of Tin.**—Evaporate the liquid, after removing copper, till only a few drops of sulphuric acid remain; take up with hydrochloric acid and water, and precipitate the tin with hydrogen sulphide; wash the precipitate with sodium chloride solution, dissolve in yellow ammonium sulphide, and evaporate to dryness on the water-bath; treat the residue with 9 grms. of potassium chlorate dissolved in water, and excess of hydrochloric acid; evaporate to dryness and dissolve residue in 30 c.c. of hydrochloric acid diluted with water; filter; add and dissolve 30 grms. of pure ammonium oxalate, heat to about 90°, and electrolyse with a current of about 0.7 ampère. The whole of the tin will be down in about 12 hours as a firmly adhering deposit. (These deposits all adhere better if the surface of the cone be roughened by depositing zinc on it, dissolving off with nitric acid, and dipping the cone into melted potassium hydrogen sulphate several times in succession.)

**Determination of Zinc.**—Boil the filtrate from the precipitated tin sulphide to expel hydrogen sulphide; evaporate on the sand-bath till only a few drops of sulphuric acid remain; dissolve the residue in water; neutralise with ammonia; add 15 c.c. of a 10 per cent. solution of ammonium citrate, 13.8 grms. of ammonium acetate (or its equivalent in acetic acid and ammonia), and 3 c.c. of glacial acetic acid. About 12 hours' electrolysis, with a current of 0.6 ampère, will deposit the zinc completely. Iron in the bronze may deposit partly with the zinc, and must then be determined by permanganate in the solution of the zinc from the electrode.

Lead is determined in bronze exactly as in commercial copper (this Journal, 1897, 164). The stannic oxide formed

during the attack with nitric acid, need not be removed; it is simply allowed to settle.

*Brass.*—Copper, zinc, and all impurities are determined exactly as above, or as in the two papers above referred to.

—J. T. D.

*Arsenic, Separation from Antimony.* O. Piloty and A. Stock. Ber. 30, 1649—1655.

ARSENIC, dissolved in strong boiling hydrochloric acid into which is led hydrogen sulphide, is completely volatile. The weighed mixture of arsenic and antimony salts is placed in a round-bottomed flask of 300 c.c. capacity and 100 c.c. of strong hydrochloric acid added. Through the cork pass two tubes. One dips under the acid, and is connected above, by a T-piece, with generators of hydrochloric acid gas and of sulphuretted hydrogen, the tube communicating with the latter being furnished with a pinch-cock. The other is a delivery tube, and dips into 250 c.c. of water acidulated with hydrochloric acid, contained in a 600-c.c. Erlenmeyer flask which stands in ice. The solution is now heated to boiling, a rapid stream of hydrochloric acid led in, and two bubbles per second of hydrogen sulphide passed. The liquid turns milky from sulphur, but clears again. In half an hour or more, nearly all the liquid has distilled over: the hydrogen sulphide is now shut off, and, after a minute or so, the flame removed and the T-piece disconnected. After cooling, the arsenic sulphide is collected on a filter on a porcelain filter-plate, then (with the portion adhering to the flask and the delivery tube) dissolved in as small a quantity as possible of dilute caustic potash solution, in a 500-c.c. round-bottomed flask. Bromine in excess is now added, the whole acidified with dilute hydrochloric acid, and boiled till all free bromine is driven off. The liquid is transferred to a 500 c.c. Erlenmeyer flask, and kept at 70° for three hours whilst hydrogen sulphide is passed through; the stream is kept up while cooling, and the liquid allowed to stand for 12 hours. The arsenic pentasulphide is collected in a Gooch crucible, washed successively with water, absolute alcohol, pure carbon bisulphide, alcohol, and anhydrous ether, dried at 105°, and weighed.

The antimony solution in the distillation flask is filtered, diluted, precipitated by hydrogen sulphide, and the sulphide treated in the same way as the arsenic pentasulphide. This simplicity in the determination of the antimony is the great advantage which this method of separation presents over the distillation with a ferrous salt.

The authors are busied with a process for the separation of tin from antimony and arsenic.—J. T. D.

*Hypophosphites.* C. T. Tyrer. Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1416], 150—152

THE author considers that the characters and tests of the U.S.P. are superior to those of the B.P., which are unsatisfactory and indefinite. The following volumetric method for the quantitative determination of hypophosphites is stated to be more accurate and generally applicable than those hitherto published:—One gram. of the sample is dissolved in water, and 5 per cent. barium chloride solution added in slight excess. The precipitated sulphite, sulphate, phosphite, and phosphate are filtered off, and may be weighed or preserved for subsequent testing. Copper sulphate solution, 10 per cent., is added to the filtrate in excess, with 5 c.c. of concentrated sulphuric acid, and the whole is then boiled for 10 minutes. The precipitate of metallic copper, together with a proportion of protoxide present, and some barium sulphate, is washed by decantation, dissolved in 30 per cent. nitric acid, sodium carbonate added until a slight precipitate is formed and then acetic acid in excess. Excess of potassium iodide is added, and the liquid titrated with thiosulphate solution, using starch solution to indicate the end reaction. If sulphuric acid be added in large excess, only one molecule of copper is precipitated, as compared with two molecules in presence of a small amount of acid. When applying this method to the iron salt, the latter is dissolved in 20 per cent. potassium citrate solution and well diluted before reduction.

The odour of sulphuretted hydrogen, which is sometimes developed by hypophosphorous acid and the syraps of the hypophosphites, is attributed to the use of charcoal as a

filtering medium. The trace of free sulphuric acid usually contained in hypophosphorous acid is reduced to sulphuretted hydrogen by boiling with charcoal, and even in the cold, on long standing. Traces of phosphate, phosphite, and sulphate are always present in hypophosphites and the sodium compound usually contains more phosphite than the other salts. A trace of carbonate should always be present in the potassium and sodium compounds; first, to ensure the absence of calcium, and secondly, to prevent the generation of a distinctive odour on keeping; this odour is stated to be probably due to spontaneous decomposition, resulting in the development of gaseous  $P_2H_4$ . Barium hypophosphite should always be tested for nitrates, this impurity occurring from the use of imperfectly prepared barium hydrate. Mixtures of barium nitrate and hypophosphite are stated to be particularly explosive. Arsenic should be tested for in all hypophosphites, being a possible impurity in badly refined phosphorus.—A. S.

#### ORGANIC CHEMISTRY.—QUALITATIVE.

*Quinones, General Reaction for Aromatic.* S. Blumenfeld and P. Friedländer. Ber. 30, 1464—1465.

UNDER ordinary conditions aromatic quinones react with phenols, forming phenoquinones or quinhydrone. These are direct addition products, are highly coloured, and are easily decomposed into their components. Thus benzoquinone and hydroquinone yield quinhydrone, whilst quinone and phenol yield pheuquinone. In presence of sulphuric acid, however, equimolecular proportions of a quinone and a phenol yield colourless condensation products, but, according to analysis, without elimination of water. For instance, one molecular proportion of  $\alpha$ -naphthoquinone is dissolved in a small quantity of acetic acid, somewhat more than one molecular proportion of pyrogallol is added, and then a few cubic centimetres of dilute sulphuric acid. A precipitate is formed which dissolves on heating, and the solution becomes colourless. On diluting with water, the condensation product separates in a crystalline form. It dissolves easily in alcohol, ether, glacial acetic acid, and acetic ether, but is insoluble in water, petroleum ether, and chloroform. It has the composition  $C_{16}H_{12}O_8$ , and melts at 240°—246° C. Similar products are obtained from benzoquinone and  $\beta$ -naphthoquinone on the one hand, and resorcinol and  $\alpha$ -naphthol on the other.—T. A. L.

*Lard, Detection of Beef Fat in.* M. Ballo. Zeits. Nahrungsm. Hyg. Waar. 11, 193—197; through Chem. Cent. 68, 392.

PURE lard, when melted and allowed to cool, solidifies with a perfectly even surface, whilst in the case of beef fat the surface is broken up or cracked, and air is enclosed in the fat. The author, in conjunction with S. Glöckner, proposes to measure the amount of enclosed air, and in this way to determine the quantity of beef fat present in mixtures of this fat and lard. The melted fat is placed in a glass vessel and allowed to thoroughly solidify. The whole apparatus is then filled with water. 100 c.c. of chloroform are now run into the vessel from a funnel fitted on to a burette, which in turn is ground into the neck of the vessel. The displaced water is allowed to run out through a side tube in the neck of the glass vessel. The tap connecting the funnel to the burette is then closed. As the fat is dissolved in the chloroform, the liberated air rises into the burette, and may be measured. Pure lard solidifies free from air, but when adulterated with more than 9 per cent. of beef fat, air is always found in the fat; even 3 per cent. may be detected. Pure beef fat gives off 6.5 to 8.8 c.c. of air; pure lard, none; lard containing 33½ per cent. of beef fat, 3.2 to 5.3 c.c. of air; and lard with 9 per cent. of beef fat, 0 to 3.1 c.c.; calculated on 100 grms. of fat.—W. P. S.

*Oil of Turpentine (French). Detection of Rosin Oil in.* A. Aignan. Comptes Rend. 124, 1367.

THE author has previously shown that since French oil of turpentine, the product of *Pinus maritima*, is levo-rotatory, and rosin oil is dextro-rotatory, a simple determination of the optical activity is sufficient to detect any considerable

admixture of the one with the other (*Comptes Rend.* 109). It is now found that by distilling off the greater part of the oil and determining the optical rotation of the residue, a very small admixture of rosin oil can be detected by the lowering of the optical rotation of this residue. Thus, by distilling 250 c.c. of oil of turpentine, containing 3 per cent. of added rosin oil, until the residue measured 70 c.c., the rotation of this for 200 mm. was only  $-36.21$ , whilst that of the same amount of residue from a like quantity of pure unmixed oil was  $-51.5$ . It was found that by conducting the distillation under reduced pressure, a dextro-rotatory residue was obtained when only so small a quantity as 0.5 per cent. of rosin oil was added.—J. O. B.

**Tannin and Gallic Acid, Action of, on Quinoline Bases.**  
O. de Coninck. *Comptes Rend.* 1897, 125, 37—38.

THE author has investigated the reactions furnished by lepidine, quinoline, and quinaldine with tannin and gallic acid under varying conditions, and finds that they closely resemble those yielded by the pyridine and hydrogenised pyridine bases, as also many volatile alkaloids, under the same conditions. (*This Journal*, 1897, 470.)—H. T. P.

**Chloral Hydrate: Reaction with Ammonium Sulphide.**  
I. Lesnisky and C. Gundlich. *Amer. Chem. J.* 19, 603—606.

To 10 c.c. of a solution of chloral hydrate (8 grms. to 100 c.c. of water), 5 c.c. of yellow ammonium sulphide are added, and the whole quickly mixed. A precipitate is formed, quite suddenly, but after the lapse of an interval of time, more or less considerable according to the temperature (at  $1^{\circ}\text{C}$ ., 44 seconds; at  $65^{\circ}\text{C}$ ., 3 seconds). The precipitate is yellow or pinkish, becoming rapidly darker when heated on the water-bath; and the filtered solution, extracted with ether, yields an oil with an odour of walnuts.

The authors suggest that this reaction may be of value in the commercial examination of chloral hydrate. They are investigating it further, both as to the nature of the products and as to the cause of the retarded precipitation.

—J. T. D.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

**Ultimate Organic Analysis, Simplification of.** M. Deanstedt. *Ber.* 30, 1590—1597.

A COMBUSTION tube 80 cm. long is charged at its middle with platinum black (prepared by the author from pyridine chlorophosphate) 6—8 cm. long, kept in place by discs of fine platinum gauze at either end. It is supported on a strip of asbestos cardboard in a sheet-iron tray, itself supported on five or six movable uprights of sheet iron, which serve at once as supports and as shields against radiation from one part of the tube to another. A cover of bent sheet iron lined with asbestos serves to keep in the heat when necessary. A couple of Teclu burners heat the platinum black to low redness at the beginning and throughout the combustion, and all other heating is done by ordinary Bunsen burners, for the most part turned low. The usual arrangements are made for burning the substance in a stream of oxygen, and for collecting the water and carbon dioxide formed. Care must be taken to have always an excess of oxygen, and to conduct the combustion cautiously until the substance is completely carbonised, after which no particular care is needed.

In front of the platinum black come two silver boats filled with molecular silver, heated to  $200^{\circ}$ — $300^{\circ}$ , and then two boats with lead peroxide, heated to  $150^{\circ}$ , each of these having been weighed. Any halogen in the substance is caught by the silver boats. Any sulphur is partly burnt to sulphuric acid, which also is completely caught by the silver boat, and partly to sulphur dioxide, which is absorbed by the lead peroxide; whilst, if the substance contain nitrogen, any of this which may be converted into  $\text{NO}_2$ , is also absorbed by the lead peroxide. The procedure when all these may be present, is as follows (the simplifications, where some are known to be absent, will be obvious):—The increase of weight of the silver boat is due to halogen +  $\text{SO}_2$ ; the boat and contents are digested in a stoppered tube with dilute potassium cyanide solution, the filtered

solution acidified with hydrochloric acid, and boiled till all HCN is expelled; in the filtrate from the silver chloride, the  $\text{SO}_2$  is determined by barium chloride: the amount of this subtracted from the increase of the silver boat, gives the halogen. The increase of the lead peroxide is  $\text{SO}_2$  +  $\text{NO}_2$ ; the contents of the boat are extracted with 33 per cent. alcohol and made up to 100 cc., and the lead nitrate in an aliquot part is determined by evaporation; the corresponding  $\text{NO}_2$  in the whole, subtracted from the increase in the peroxide boat, gives the  $\text{SO}_2$  from which, along with the  $\text{SO}_2$  in the silver boat, the sulphur is calculated. Proofs of the accuracy of the work are given:—In a test analysis, *p*-bromophenylurea,  $\text{C}_6\text{H}_4(\text{NH}.\text{C}(\text{H})\text{Br})_2$ , gave—

H, 2.59; C, 40.31; S, 8.29; Br, 41.45;
calc. 2.80 40.44 8.31 41.67

Not only are chlorine and sulphur thus determinable in one operation with carbon and hydrogen, but no special combustion furnace is needed and no special room; little time is taken up, and the combustion tubes last out many operations.—J. T. D.

**Sugars, Iodometric Estimation of.** G. Romijn. *Zeits. Anal. Chem.* 36, 349—359.

HAVING shown (*this Journal*, 1897, 366) that oxidation by iodine in alkaline solution affords a convenient and exact method for the determination of formaldehyde, and that other aldehydes are also attacked, the author has attempted to extend the method to estimation of the sugars.

The oxidation of the reducing sugars in alkaline solution by various reagents, even by atmospheric oxygen, proceeds readily, although it is doubtful whether the reaction is a simple one. If, however, this were so, and if glucose were oxidised to gluconic acid according to the equation—

each c.c. of  $\frac{1}{10}\text{N}$  iodine solution acted on would thus represent 9 mgrms. of glucose. It is found that in the presence of free alkali the decomposition proceeds further, so that it is better to supply the necessary alkali as sodium and ammonium carbonate, potassium bicarbonate, trisodium phosphate, and borax, all of which were tried. Although in presence of borax the action is slow, the reagent has the advantage of sharply differentiating glucose and levulose, or, generally, aldoses and ketoses. On mixing borax with solution of iodine in potassium iodide, the brown colour becomes only slightly lighter; there is consequently only a small quantity of hypoiodite and iodate formed. The solution, however, acts on thiosulphate, as Töpfer found (*ibid.* 26, 137), with alkali carbonates and bicarbonates; that is, less thiosulphate is necessary for the reduction than for the acidified solution, and the difference is only partly made up on acidifying by the iodine set free from the iodate formed. A part of the thiosulphate is therefore oxidised to sulphate. From solutions titrated alkaline, the iodine set free on acidifying, was very small in fresh solutions, and even on warming to  $60^{\circ}$  or  $70^{\circ}\text{C}$ ., or in old solutions, amounted to only 12—30 per cent. of the quantity obtained on titrating the previously acidified solution. The mixed solution may therefore be kept without fear of a great decrease in titre. It is best prepared by dissolving the borax in a portion of the water by warming, and after the solution is cool, adding the concentrated iodine solution and making up to a definite volume. The solution used by the author contained, in 25 c.c., 1 gm. of borax, and iodine sufficient to require for its decolorisation, after acidifying, 30—33 c.c. of  $\frac{1}{10}\text{N}$  thiosulphate solution. If 25 c.c. of this solution is mixed with a definite quantity of a solution of glucose, it is at first quickly reduced, and then more and more slowly. On acidifying and titrating with thiosulphate, the remaining iodine is determined and the difference calculated to sugar. The results are found to be influenced by the temperature, by time, and by quantity of sugar.  $25^{\circ}\text{C}$ . was chosen as the most suitable temperature. The test is made in a narrow-necked flask closed with a glass stopper. After the sugar solution and the borax-iodine solution are introduced by a pipette, the stopper is fastened by wire and a drop of water placed round the rim, and the flask is placed in a thermostat. After being heated

for a definite time, 1.5 c.c. of hydrochloric acid is added, of sp. gr. 1.126, and the iodine titrated. The values obtained by using 35—50 c.c. of solution and acting for 16—22 hours on 151—164 mgrms. of sugar varied from 97.76 to 99.47 per cent. of the sugar taken. The reaction may be regarded as complete in 16—22 hours, for 20—24 hours later only about 2 per cent. more sugar was found. On great dilution the results are higher, due to the hydrolytic dissociation of the borax; for when this is prevented by the addition of boric acid, the action is greatly retarded.

Under similar conditions, levulose is scarcely attacked. Herzfeld (*Zeits. f. Rübenzuckerind.* 35, 967) states that, although levulose is more sensitive to alkalis than glucose, it exhibits greater resistance to oxidising substances in alkaline solution; but a sharp distinction of this kind was not to be expected. At 25° C., in 17½ to 19 hours, from 2.23 to 3.22 per cent. of the quantity of levulose taken was found; in 10 to 42½ hours, 5.04 and 5.60 per cent. At higher temperatures glucose is more quickly oxidised, but levulose is also more strongly attacked. It is possible that at lower temperatures a still sharper distinction might occur, but the determination would then require too long a time, and it would be inconvenient to maintain a lower temperature than 25° C. in the summer months. The behaviour of nearly all the simple sugars and some compound sugars were examined, towards borax-iodine. It was found that the aldoses—galactose, mannose, arabinose, xylose, and rhamnose—behaved in the main as glucose does. The results appear to show small variations in oxidisability, and it is possible that different isomers are differently attacked; but the difference is insignificant, and requires further investigation with more abundant material. Chitosamine chloride, which Lobry de Bruyn and Alberda van Eckenstein have shown easily passes into a derivative of levulose, is oxidised by borax-iodine as an aldose. Sorbose suffers as little oxidation as levulose. The compound sugars are more strongly attacked than was to be expected from their constitution. For maltose and lactose this is not very surprising; but saccharose, raffinose, and stachyose, which do not reduce alkaline copper solution, are strongly oxidised; consequently it is not possible to conclude as to the presence of aldoses from reduction alone.

Among other organic substances examined, those forming iodoform caused a strong reduction, acetaldehyde being a surprising exception. No separation of iodoform was observed in the case of ethyl alcohol, but much with lactic acid and acetone. The simultaneous formation of oxalic acid from lactic acid affords an excellent reaction for identifying that substance. Glycerin and mannitol were also strongly attacked, owing to their capability of forming compounds with boric acid. The behaviour of formic acid is also worthy of notice. In the short time required for the determination of formaldehyde, no irregularities indicating further oxidation were observed; but, on this account, borax-iodine is unsuitable for the determination of formaldehyde.

Various mixtures of sugars were now tested. It was found that the presence of levulose produces no alteration in the oxidation of glucose. Mixtures of these sugars may therefore be determined as pure glucose. Cane sugar acts otherwise, but the difference is small, as with five times as much saccharose as lactose, the result was only increased by 2 per cent. Milk sugar may thus also be tested in the presence of cane sugar.

Mannitol, however, greatly retards the oxidation of glucose—a phenomenon in accord with the increase in the conductivity of boric acid on the addition of mannitol observed by Magnanini (*ibid.* 30, 467); and glycerin appears also to form a similarly easily oxidisable compound.

Although the above method thus allows of a convenient and exact determination of aldoses, either alone or mixed with ketoses and other bodies, it is not immediately applicable in practice, as the glycerin in wine and uric acid in urine, would cause errors in estimating the sugar.

—L. J. de W.

*Volatile Acids in Wine. Estimation of.* F. Gayon. *Revue de Viticulture; La Bière*, 5, [6], 81—82, and [7], 97—100.

In the normal (alcoholic) fermentation of grape-must, not more than 20 to 25 centigrams. of volatile acids, expressed

in monohydric sulphuric acid, are produced per litre; but as the yeast becomes weaker, the microbes obtaining access quickly increase the (volatile) acidity, as shown by determinations made by the author in two vats of 1896 wine, wherein this acidity was raised from 0.12 gm. per litre (in the absence of microbes) to 0.36 gm. within 8 days in the one case, where 35 to 40 microbes were detectable in the microscopic field, and to 0.45 gm. in the same time in the second sample, which revealed 50 to 60 microbes. In this instance the usual increase of total acidity noticeable in diseased wines was masked by the precipitation of tartar under the influence of alcohol and reduced temperature (29° C. maximum). That the injurious ferments do not always make their appearance at the same stage is demonstrated by the fact that in the first sample, 22.7 grms. of sugar were still present per litre at the time of infection, whereas in the second sample there was only 1 gm. per litre unconsumed, the fermentation being at an end and the wine only left to allow the colour to deepen. The date of the appearance of the microbes varies according to a number of circumstances, including temperature, weather, maturity of the grapes, dimensions of the fermenting vat, &c., infection being noticed in 1896 on the 16th—17th day, from the 9th to 12th day in 1880 and 1888, and on the 4th day in 1891. In 30 samples of 1896 wine examined by the author, only a single one was destitute of microbes, and this was found to contain only 0.2 gm. of volatile acidity per litre, the figures for the others ranging from 0.3 up to as much as 0.6 gm. in Gironde wines, and even to 0.8 gm. in a Narbonne wine.

The Bordeaux wines are all infected with germs capable of producing disease in the environment, and these continue to develop in bottle, despite rackings, finings, and mixings; but in the earlier stages, the volatile acids they excrete do not always spoil the flavour of the wine, a transient improvement being effected in some cases until the limit of 1 gm. per litre is exceeded.

The influence of temperature on the maturing of wine is exemplified by an 1887 Medoc wine, part of which was stored in a cool, and the rest in a warm cellar; the former, after 8 years in store, being quite sound, and only containing 0.92 gm. of volatile acidity; whereas the second had "turned," and gave 2.31 grms. per litre. Very similar results were obtained with a mixture of 1890 and 1891 vintages under the same conditions.

The percentage of volatile (acetic) acid has also been found to increase concurrently with the progress of mannitic fermentation.

For the estimation of these acids, the following modification of the Pasteur method is recommended as being quicker than the original, and capable of performance on a smaller sample.

Ten c.c. of the wine and 20 c.c. of water, are distilled in a tubulated retort, connected with a glass condenser. When 20 c.c. of distillate have passed over, an equal quantity of water is poured into the retort, and a second 20 c.c. of distillate collected, this procedure being repeated until the distillate is no longer appreciably acid. The successive fractions collected, are then titrated with calcium hydroxide solution (titer 4.7), and the acidity calculated from the amount of reagent consumed. The results agree with those obtained by the Duclaux method, which requires a larger quantity of substance, but is more expeditious in cases where the wine is rich in volatile acids; on the other hand, the modified Pasteur method gives an earlier indication of the acidity present, the quantity contained in the first distillate representing approximately one-half of the total.—C. S.

*Boric Acid in Milk, Detection of, and Rapid Method of Determination.* G. Denigès. *J. Pharm. Chim.* 6, (2), 49.

If to a milk containing boric acid, some phenolphthalein be added, and then decinormal soda till a very faint rose tint is produced, and afterwards a little neutral glycerin (about one-fourth the volume of the milk), it will be noticed that the rose tint at once disappears. In order to restore the original colour, it will then be necessary (especially if to assist the process, as much alcohol be added as was added

of glycerin) to add an amount of the alkali solution serving as a precise measure of that amount which, on the one hand, the borated milk alone would absorb, and that, on the other which an equal volume of an aqueous glycerin solution of boric acid of the same strength would require. It will be visible how on this basis a method may be devised for the rapid estimation of boric acid in milk.

Two flasks, each containing 20 c.c. of the sample of milk, are placed on a white background, and to one of them a few drops of phenolphthalein solution are added, followed by sufficient  $\frac{1}{10}$  N. NaHO solution to give a barely perceptible rose tint, readily observed by comparing with the other flask. 10 c.c. of a mixture of equal parts of alcohol, 90 per cent. and of glycerin, is then run in. If the rose tint persists, borax may be considered as absent; if it be present, the red coloration disappears and the mixture is titrated with  $\frac{1}{10}$  N. NaHO solution until it is brought back. The number of c.c. employed in this second titration is noted and the amount of boric acid calculated with the following correction for the action of the lactose in the titration. When N = number of c.c. employed,  $N - 0.15 =$  number of grms. per litre of boric acid added. This correcting figure has been established by actual experiment, but it only holds good where the amount of boric acid does not exceed 3 grms. per litre, and when the lactose (as in normal milk) ranges from 40 to 50 grms. per litre. When the amount of boric acid exceeds this figure, the sample must be diluted with an equal volume of water and sufficient milk sugar added to bring the amount up to 40–50 grms. per litre. When borax has been used as a preservative, half a c.c. of  $\frac{1}{10}$  N. HCl solution must be added before the first neutralisation. —J. O. B.

*Digitalis, Determination of Active Principles of.* C. C. Keller. Ber. deutsch. Pharm. Ges. 30, [7], 125; through Pharm. J. 59, [1413], July 24, 1897, 62.

THE author advocates the following method for the determination of digitoxin in foxglove leaves. This substance is freely soluble in alcohol and chloroform, and is precipitated by water and dilute alcohol, also by tannin, but not by basic lead acetate. It can be washed out with chloroform from acid or alkaline solutions. Digitalin and digitonin are almost insoluble in chloroform. The leaves are extracted by percolation with 70 per cent. alcohol, until the residue from 3 or 4 c.c. redissolved in acid water, gives no precipitate with tannin. The alcohol is distilled off, the residue dissolved in water and precipitated by basic lead acetate, filtered, washed, excess of lead removed with sodium sulphate and the clear filtrate, made faintly alkaline with ammonia, is washed out with several successive portions of chloroform. The solvent is evaporated, the residue dissolved in 3 c.c. of chloroform, 7 c.c. of ether, and 10 c.c. of petroleum spirit are added, when the digitoxin is precipitated in flocks. For weighing, this precipitate may be redissolved in hot alcohol, and the solution evaporated in a tared vessel, or the petroleum spirit may be decanted off, and the digitoxin weighed in the form of powder. A solution of digitoxin in glacial acetic acid containing ferric chloride, when floated upon strong sulphuric acid, gives at the line of contact, a dark zone and gradually the acetic solution becomes dark blue. This reaction is given by  $\frac{1}{10}$  mgrm. of digitoxin.

The aqueous solution from which digitoxime has been removed by chloroform contains digitonin, which may be precipitated with tannin. The author was not able to isolate digitalin which he regards as a mixture of digitonin with traces of digitoxin and of digitalin. He concludes that the leaves, like the seeds, contain digitalin, digitoxin, and digitonin, but that the proportions of each are somewhat different, good leaves containing more digitoxin than the seeds. The amount present in the leaves is, however, very variable, ranging from 0.26 to 0.62 per cent. Pharmaceutical preparations were found to vary still more, and the author advocates their standardisation by the amount of digitoxin contained in them. —J. O. B.

*Commercial Egg Albumin, Estimation of.* P. Carles. J. Pharm. Chim. 1897, 6, [3], 102.

Two grms. of the sample are dissolved in a small quantity of water and gradually diluted, with constant stirring, to

200 c.c. If free from coagulated albumin this solution will be clear. 100 c.c. of this are taken and 35 c.c. of a 1 per cent. pure tannin solution added, and a pinch of powdered potassium bitartrate. The mixture is well shaken, then thrown on a plain filter, and the clear filtrate divided into two equal parts in twin tubes. To one a few drops of solution of transparent gelatin is added; to the other a like quantity of tannin solution. If both remain clear, the egg albumin is pure and of good quality. If the gelatin solution cause a precipitate, it shows that the egg albumin is weak and of poor quality, either from a portion having coagulated by overheating in the course of manufacture, or by the fraudulent addition of non-coagulating matter. On the other hand, if the tannin solution give a precipitate, it is due to the presence of gelatin, which has about four times greater precipitating power for tannin than egg albumin; but, since it is not coagulated by heat, it is worthless for a majority of technical purposes, such as clarifying liquids, for which egg albumin is used. A further test is to heat 100 c.c. of the solution gradually on the water-bath. In this way the whole of the egg albumin will be coagulated, and the filtrate from the pure substance will give no precipitate with tannin; gelatin, however, is not so coagulated, and will give a copious precipitate with that reagent. In this filtrate also, dextrin, gums, and other adulterants, if present, will be found. —J. O. B.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Precipitated Chalk, Dimorphism of.* M. Adler. Zeits. angew. Chem. 1897, 431.

IN precipitating calcium carbonate, the speed with which the trimetric crystals of arragonite change into the rhombohedra of calc spar depends partly on the temperature of the liquids, but rather on that of the ammonium carbonate solution than on that of the calcium chloride; and below 32° C., the more concentrated the alkaline liquid the more permanent are the rhombs. This is due to the dissociation of the ammonium carbonate, for, as Rose pointed out, in an atmosphere of carbonic acid gas only calc spar is produced. If it be necessary to work with dilute solutions, and it be desired to obtain arragonite, the temperature should be kept as low as possible, and must not exceed 22°. The colder the liquids the smaller and more stable are the rhombic crystals. Increased pressure also assists the conversion, for while the rhombs will bear a pressure of 2 atmospheres without change, on raising it to 4 or 5, rhombohedra begin to be produced, and at 6 atmospheres the precipitate feels gritty between the fingers. Dilution of the calcium chloride with calcium sulphate solution, instead of plain water, causes the arragonite to be as permanent as though it had been thrown down from concentrated liquids. If the chalk be precipitated by means of sodium carbonate, it will bear a temperature of 100° without alteration; but in the event of using the ammonium salt, it should be dried as quickly as possible at or below 60° C. in a current of air. —F. II. L.

*Nitrates in Presence of Ether, Action of Dilute Nitric, Sulphuric, Hydrochloric, and Phosphoric Acids on.* C. Tanret. Bull. Soc. Chim. 1897, 497–503.

WHEN two liquids insoluble or only slightly soluble in each other are shaken together, and one of them contains a substance soluble in either, the two liquids divide the substance in such a manner that the quantities dissolved in the same volume of each are in a constant ratio. Berthelot and Jungfleisch have characterised this as the *coefficient of distribution*. In the case of an aqueous solution of an acid shaken with ether, the coefficient varies from 1:91 to 1:130 for tartaric acid and from 1:1.2 to 1:1.23 for acetic acid, whilst for dilute sulphuric, hydrochloric, and phosphoric acids, it is as low as from 1:2700 to 1:500. Thus, owing to the great difference in their coefficients of distribution it is possible to separate for the greater part, organic acids from these three mineral acids. Nitric acid, however, in a liquid rich in ammonium nitrate, passes over into the ether like an organic acid, but when the ether is shaken with water the acid is taken up by the latter, and hence nitric acid has different coefficients according as to whether

ammonium nitrate be present or not. As an outcome of this observation and by acting on alkaline nitrates with dilute acids, the author's experiments have led to the following conclusions:—Since sulphuric, hydrochloric, and phosphoric acids liberate nitric acid from nitrates, the presence of a small quantity of these free acids is easily detected in a liquid, if after having saturated it with an alkaline nitrate, it is extracted with ether and the latter is then shaken with water, when the nitric acid which passes into it can be readily characterised.—T. A. L.

*Sulphantimonites of Silver.* Pouget. *Comptes Rend.* 1897, 124, [26], 1518—1520.

Potassium sulphantimonite, with silver nitrate in dilute solution, gives a black precipitate of  $\text{SbS}_3\text{Ag}_3$ . If the potassium sulphantimonite be strong, and in sufficient excess, this black precipitate, formed in the first instance, is converted rapidly into a yellow crystalline precipitate of  $\text{SbS}_3\text{Ag}_3\text{K}$ . This salt can also be obtained by the action of potassium sulphantimonite on previously formed silver sulphantimonite. It is decomposed by alkaline sulphides with formation of silver sulphide, and by the action of water is broken up, slowly in the cold, more rapidly when heated, into potassium and silver sulphantimonites.

Whatever the concentration or the temperature of the solution of potassium sulphantimonite, addition of a sufficiency of silver nitrate determines the formation always of the black precipitate, which, when so formed is not of constant composition, containing always more  $\text{Ag}_2\text{S}$  than corresponds with the formula  $\text{SbS}_3\text{Ag}_3$ , but which is always free from potassium.

The salt  $\text{SbS}_3\text{Ag}_3\text{K}$  has not yet been obtained by the author.—J. T. D.

*Petroleum in the Cavities of Fossils, Occurrence of.* F. C. Phillips. *Proc. Amer. Phil. Soc.* 36, [154], 121—126.

A CASE of irregular deposition of oil and bitumen in coral, occurs in a quarry at Williamsville, N.Y. Owing to the quantity present and the apparent absence of sediment above the coral, it does not seem as though the oil could have been formed *in situ* from the comparatively small amount of vegetable matter in the coral cells at any one time during the growth of the reef. The cause of infiltration may probably be a displacement by water of oil formerly distributed in the adjacent (limestone) rock.—C. S.

## New Books.

*MANUALE DEL CHIMICO E DELL'INDUSTRIALE.* Raccolta di Tabelle, di Dati Fisici e Chimici e di Processi d'Analisi Tecnica ad uso dei Chimici Analitici e Tecnici, dei Direttori di Fabbriche, dei Fabricanti di Prodotti Chimici, degli Studenti di Chimici, ecc., ecc. Del Dr. LUIGI GABBA, Prof. Ord. di Chimica Tech. nel R. Instit. Techn. Superiore e nella R. Scuola Super. d'Agricoltura di Milano. Seconda Ediz. Ampliata. Milan: Ulrico Hoepli, Editore-Libraio della Real Casa. 1898. Price L. 5.50. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS little work, resembling Biedermann's *Chemiker-Kalender*, is furnished with data and tabulated matter bearing reference to the various branches of Chemical Industry, as well as to weights and measures, temperatures, specific gravities, &c. The book contains preface, table of contents, 128 pages of subject-matter, and an alphabetical index. The general plan is as follows:—I. Money System and Weights and Measures. II. Physical Data. III. Chemical Data. IV. Applied Chemistry: i. Chemical and Technical Analysis of Water. ii. Analysis of Minerals and Metals. iii. Analysis of Alloys. iv. Analysis connected with the Alkali Industry. v. Composition and Analysis of Glass. vi. Analysis connected with the Ceramic Arts. vii. Mortars and Cements. viii. Fuels and Illuminants. ix. Fatty Matters, Waxes, and Stearin. x. Oils, Fats, &c. xi. Analysis of Mineral Lubricating Oils. xii. Analysis of Resins and Varnishes. xiii. Soaps, and Data relating to

Saponification. xiv. Textile Fibres. xv. Agricultural Products, &c. xvi. Food Analysis, &c. xvii. Dyestuffs. xviii. Sugars, Starches, &c. xix. Tanning. xx. Explosives. xxi. Analysis of Urine, &c. xxii. Photography. xxiii. Chemical Data on Hygiene. xxiv. Various Data.

*LA FABBRICAZIONE DELL' ACIDO SOLFORICO, DELL' ACIDO NITRICO, DEL SOLFATO SODICO, DELL' ACIDO MURIATICO.* Del Dr. V. VENDER, Chimico Consulente a Milano, già Chimico e Direttore di Fabbriche. Milan: Ulrico Hoepli, Editore-Libraio della Real Casa. London: H. Grevel and Co., 33, King Street, Covent Garden. 1897. Price L. 3.50.

SMALL volume, pocket-book size, like the preceding, containing subject-matter, data, and tables, &c., with reference to the Manufacture of Sulphuric Acid. There are 312 pages of subject-matter, illustrated with 107 woodcuts, and an alphabetical index of authors and inventors. The work is divided into four sections, as follows:—Manufacture of Sulphuric Acid. Manufacture of Nitric Acid. Manufacture of Hydrochloric Acid. Tables.

*LEGHE METALLICHE ED AMALGAME ALLUMINIO, NICHELIO, METALLI PREZIOSI E IMITAZIONI BRONZO, OTTONE, MONETE E MEDAGLIE, SALDATURE.* Dell' Ingegnere I. GHERSI. Milan: Ulrico Hoepli, Editore-Libraio della Real Casa. London: H. Grevel and Co., 33, King Street, Covent Garden. 1898. Price L. 4.

SMALL volume, pocket-book size, like the preceding, containing subject-matter covering 405 pages, and furnished with curve diagrams, tables, &c., and alphabetical indexes of subject-matter and authors' names. The sub-divisions of the text are as follows:—I. Alloys in General. II. Binary Alloys. III. Alloys of Aluminium, &c. IV. Nickel Alloys. V. Amalgams. VI. Gold Alloys. VII. Silver Alloys. VIII. Platinum Alloys. IX. Alloys for Coinage and Medals. X. Bronzes. XI. Ternary Alloys, &c. Delta Metal, Fusible Alloys, Solders, &c. XII. Appendix.

*DIE UNTERSUCHUNG, DER SCHMIERMITTEL UND VERWANDTER PRODUKTE DER FETT- UND NAPHTHA-INDUSTRIE.* Von Dr. D. HOLDE, Vorsteher der Abth. für Oelprüfung an der königl. mech.-tech. Versuchsanst. zu Charlottenburg. Berlin: Verlag von Julius Springer. 1897. Price M. 7. London: H. Grevel and Co., 33, King Street, Covent Garden.

8vo volume containing 256 pages of text, illustrated with 59 wood engravings, and an alphabetical index of subject-matter. The treatise deals with the following subjects:—A. Lubricants and their Requirements. B. Lubricating Arrangements, &c. C. Composition, Properties, and Production of Lubricating Oils. D. General Methods of Testing: i. General Properties. ii. Physical Tests. iii. Chemical Tests. E. Special Tests. i. Of Vegetable and Animal Oils and Fats. ii. Of Mineral Lubricating Oils. iii. Of Mixtures of Mineral and Fatty Oils. iv. Testing Lubricants of Considerable Consistency. v. Testing Oils for Tool Machinery. F. Appendix.

*CHEMISCH-TECHNISCHES REFERATORIUM.* Uebersichtlicher Bericht über die neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie, mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 36. Jahrgang. 1897. Erstes Halbjahr. Erste Hälfte. Mit in den Text gedruckten Illustrationen. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder, S.W., Schönebergerstrasse 25. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS number, for the first half-year of 1897, treats of the following subjects of applied chemistry:—Building Materials, Cements, and Artificial Stones. Dyestuffs, Colours, and Calico-Printing. Fats, Oils, Illuminants, and Fuels. Fermented Liquors. Tanning, Leather, and Glue Manufacture. Textiles. Glass and Earthenware. Wood and Horn. India-Rubber and Gutta-Percha. Cements and Agglutinants. Lakes, Varnishes, and Paints. Metals.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

#### BELGIUM.

##### Tariff Modifications.

The *Moniteur Belge* of the 22nd August last, publishes the provisions of a law which passed the Chamber on the 6th August last. The principal articles of the above law are as follows:—

Art. 1. The import duty on tea is abolished.

Art. 2. Beetroots must pay an import duty of 1 fr. per 1,000 kilos. from 1st July 1898.

Art. 3. Sec. 1. The final paragraph of the first section of the first article of the law of the 16th April 1887 is to read as follows:—

"Syrups and molasses of a total saccharine strength of less than 50 per cent., 18 frs. per 100 kilos."

Sec. 2. The second section of the article cited above is to read as follows:—

"Refined sugar, known as 'vergeuses,' brown sugar, or bastard sugar are assimilated to raw sugars as far as the import duties are concerned. Syrups and molasses of a total saccharine strength of 50 per cent. or more, as well as 'melados,' are assimilated to raw sugars of the 4th class."

Art. 4. Sec. 1. The importation, manufacture, transport, storing, or sale of saccharin and similar substances are forbidden. This prohibition applies to products containing saccharine or similar substances.

Sec. 2. By substances similar to saccharine are meant chemical products having a sweet taste, but of no value as an article of food.

Sec. 3. Exception to the above articles will be made in favour of saccharin and similar substances imported by pharmacists for medicinal purposes.

Sec. 4. The Minister of Finance will determine the conditions and formalities to be observed by pharmacists benefiting by Sec. 3.

The abolition of the duty on tea will come into force on 1st January 1898.

The alteration in the duty on syrups and molasses came into force on 23rd August last.

#### VENEZUELA.

##### Tariff Modifications.

The following modifications in the Customs tariff of Venezuela are published in the *South American Journal* of 24th July last:—

The following is a list of such articles as enter duty free:—Mineral waters, which formerly paid 4 cents per kilo.

The following, second class, pay 2 cents per kilo.:—Liquid carbonic gas, elbow tubes, glass dust.

Third class, 5 cents per kilo.:—Asbestos, Muscovado sugar, formerly prohibited; gum arabic, formerly 25 cents per kilo.; butter, excluding oleomargarine; chemical products for curing skins, which formerly paid 25 cents per kilo.

Fourth class, 15 cents per kilo.:—Refined sugar, formerly prohibited, harness oils, oil cloth, naphtha, lard.

Fifth class, 25 cents per kilo.:—Alcohol of every sort except cane above 22° Cartier, which will pay duty corresponding to the sixth class, 50 cents per kilo.

Seventh class, 1 dol. per kilo.:—Matches, formerly in this class, are prohibited.

#### NEW CUSTOMS TARIFF OF CAPE COLONY.

An Act to amend the Customs Union Tariff Act of 1889 came into force on the 1st July last, and the following are some of the rates of duty levied thereunder:—

#### SCHEDULE A.

##### CLASS I.—Special Rates.

No.	Article.	Rate.
		£ s. d.
1	Alc. beer, and cider, all kinds, of strength exceeding 2 per cent. of proof spirit:— (a.) In vessels of not greater content than one imperial quart.....	Per imp. gall. } 0 1 6
	(b.) In other vessels, bulk or wood.....	" } 0 1 3
2	Acetic acid.....	Per lb. } 0 3 0
3	Blasting compounds, including all kinds of explosives suitable and intended for blasting, and not suitable for use in firearms.....	Per lb. } 0 0 3
7	Cement.....	Per 100 lb. } 0 0 6
23	Gunpowder and other explosives suitable for use in firearms.....	(and 9 per cent. ad val. in addition).
28	Ochre (commonly known as "Kadir ochre").	Per 100 lb. } 0 5 0
29	Oils: (a.) Paraffin and kerosene.....	Per imp. gall. } 0 0 3
	(b.) Anthracene, brick, coal, or gas-tar, coconut, cotton seed, hemp seed, palm and palm kernel, shale, and any other kinds, being in a crude and unrefined state, for making anti-friction grease, candles, or soap, or burning as fuel in oil engines, not including fish-oil.	Per ad valorem.
	(c.) Essential and perfumed.....	20°
	(d.) Other than above, including fish-oil.....	Per imp. gall. } 0 1 0
34	Salt, rock.....	Per ton } 0 2 0
35	Salt, common, not including refined or table salt.....	" } 6 5 0
36	Soap, not including toilet soaps and soap powders and extracts.....	Per 100 lb. } 0 4 2
38	Spirits: (a.) Perfumed.....	Per imp. gall. } 1 6 0
	(b.) Liqueurs and cordials exceeding 2 per cent. of proof spirit.....	" } 0 15 0
	(c.) Other sorts, exceeding 2 per cent., but not exceeding the strength of proof by Sykes' hydrometer, and 50 per cent. in proportion for any greater strength.	" } 0 15 0
39	Sugar: (a.) The produce of the cane, of refined, golden syrup, molasses, saccharum, and treacle.....	Per 100 lb. } 0 3 6
	(b.) Not cane, and all refined sugars.....	" } 0 5 0
47	Vinegar, of standard strength, fit for immediate use as such (i.e., requiring no more than 40 grains of $\text{KHC}_2\text{O}_4$ to neutralise 1 oz. Troy); (a.) In bottles or other vessels, of the capacity of not more than one imperial quart.....	Per imp. gall. } 0 1 6
	(b.) Do., do., in larger vessels or in bulk.....	" } 0 0 6
	(c.) Concentrated extract or essence, of greater strength than above.....	" } 0 3 0

##### CLASS II.—Free.

No.	Article.
58	Asbestos packing and boiler composition.
68	Brass and copper in bars, manufactory.
79	Gambier, myrobolans, sunnatch, and other dyestuffs for leather (in bulk).
82	Fireclay and firebricks.
84	Flowers of sulphur and other substances (in bulk) for destroying diseases in animals or plants.
87	Glue.
92	Guano and fertilisers generally.
93	Lead.
95	Leather in the piece, all kinds.
99	Papers for printing or lithographic purposes.
102	Potash or soda, carbonate, bicarbonate, caustic, crystals, and silicate (in bulk).
108	Resin and carbonate of ammonia.
113	Sheep dip, powder, and dipping tanks.
119	Tin and zinc.
123	Vaccine virus, and toxin.

##### CLASS III.—General: Ad Valorem 9 per Cent.

131	All goods, wares, or merchandise not elsewhere charged with duty, and not enumerated in the free list, and not prohibited to be imported into the Union, shall be liable to a duty of 9 per cent. ad valorem.
-----	---

CLASS IV.—Special: *Ad Valorem* 20 per Cent.

The following articles shall be liable to a duty of 20 per cent. *ad valorem*:—

135	Extracts and essences of all kinds used as food, flavouring, or perfumery, including saccharine.
136	Fireworks of all descriptions.
137	Patent and proprietary chemicals, drugs, or medicines, and all medicated foods.
138	Perfumery, cosmetics, powders, and soap or other preparations for toilet use, and soap powders and extracts.

## NEW TARIFF OF JAPAN.

U.S. Cons. Reps., Sept. 1897, 91.

The United States Minister at Tokyo reports that a statutory Tariff Bill regulating the Customs dues to be levied in all cases where Japan is not bound by treaty stipulations, was passed by the lower house of the Diet on the 17th March, and has received the Imperial assent.

The following are taken from this law:—

(a.) *Tariff annexed to Protocol of the Anglo-Japanese Treaty signed at London, July 16, 1892.*

	<i>Ad Val.</i> Per Cent.		<i>Ad Val.</i> Per Cent.
Caoutchouc, manufac- tures of.....	10	Oil, paraffin.....	10
Cement.....	5	Paint in oil.....	10
Glass, uncoloured.....	8	Paper, printing.....	10
" stained.....	20	Sugar, refined.....	10
Indigo, dry.....	10	Saltpetre.....	5
Lead.....	5	Tin, block.....	5
Leather, sole.....	15	" plates.....	10
" other kinds.....	10	Wax, paraffin.....	5
Mercury.....	5	Zinc, pig.....	5
		" sheet.....	7½

(b.) *Tariff annexed to the Protocol of the Japanese-German Treaty (Official Gazette, Nov. 20, 1896).*

	<i>Ad Val.</i> Per Cent.		<i>Ad Val.</i> Per Cent.
Lead, pig.....	5	Dyes and paints:—	
Chemicals, drugs, and medicines:—		Anilin and alizarine dyes.....	10
Phosphorus, red.....	10	Logwood extract.....	10
Subnitrate of bismuth.....	10	Paints in oil.....	10
Bromides.....	10	India-rubber manufac- tures.....	10
Quinine.....	8	Leather, sole.....	15
Chlorate of potash.....	10	" other sorts.....	10
Dynamite.....	10	Papers.....	10
Iodide of potassium.....	10	Paraffin oil.....	10
Nitrate of potash.....	5	" wax.....	5
Salicylic acid.....	10	Portland cement.....	5
Window glass, plain.....	8	" block.....	5
" stained.....	10	" plates.....	7½
		Sugar, refined.....	10

(c.) *Tariff as passed by Bill of Imperial Parliament and published in the Official Gazette.*

## CLASS I.—DUTYABLE.

Section I.—Scientific  
Apparatus.

	<i>Ad Val.</i> Per Cent.

CONSULAR REPORTS.

## THE PHOSPHATE CONCESSIONS IN ALGERIA.

*Bd. of Trade J., Sept. 1897, 338.*

A despatch, dated 5th August last, has been received at the Foreign Office from Sir Edmond Monson, Her Majesty's Ambassador at Paris, enclosing copy of the report laid before the Chamber of Deputies by the Commission appointed to examine a Bill for the working of the phosphate beds in Algeria.

This document commences with an exhaustive account of the present condition of the phosphate trade, and then goes on to examine the steps necessary for regulating the Algerian workings.

The Commission are of opinion that, as France possesses a sufficient supply of phosphates for all her wants, there is no need to monopolise for her use any of the Algerian produce; and they are in favour of steps being taken to promote the development of this industry as a source of wealth to the colony. They consider, therefore, the proposal of the Government to establish an export duty of 2 frs. per ton as unnecessary.

The Commission also come to the decision that all the phosphate beds in the extreme south of Algeria should belong to the State.

Although no express statement is made, it would appear that, as far as the Commission are concerned, there is no intention to interfere with the concessions granted to Messrs. Crookston Brothers, of Glasgow, and the Constantine Phosphate Company, of Leith, but no information is to hand as to the actual state of their case, which, from the last reports, was still under the consideration of the Conseil d'Etat.

## DECLINE IN THE BAVARIAN GLASS TRADE.

*Bd. of Trade J., Sept. 1897, 336.*

A despatch, dated 31st July last, has been received at the Foreign Office from Mr. V. Drummond, Her Majesty's Minister at Munich, reporting a serious decline in the Bavarian glass trade with America.

At Furtth, one of the most important manufacturing towns in Bavaria, the glass exports to America, which amounted in 1891 to 380,000*l.*, were last year only 185,000*l.* Since 1893, the year of the commercial crisis, Bavarian glass manufacturers have had to cut down the working power of their establishments, which, even with this diminished power, they have been keeping up at a great sacrifice in the hopes of better times. The new American tariff, however, not only dissipates the idea of any improvement, but makes it clear that the Bavarian glass industry is placed in a serious position, and the preservation of the United States market, which formerly took more than three-fourths of the whole Bavarian looking-glass trade, is now a question of life for it.

#### ESTABLISHMENT OF A SUGAR REFINERY AT LOURENÇO MARQUES.

*Bd. of Trade J., Sept. 1897, 338.*

A despatch, dated 4th August last, has been received at the Foreign Office from Sir H. G. MacDonell, Her Majesty's Minister at Lisbon, stating that, according to the *Diário de Notícias*, the Royal Commissioner of Mozambique has sanctioned the concession granted by the Governor of Lourenço Marques to Mr. Johannes Bang for the establishment in that district of a sugar refinery, advantage being taken of the produce of the same for the distillation of alcohol.

The alcohol thus produced will pay a duty of 27 reis per litre on exportation, or of 260 reis a litre when destined for local consumption.

#### FOREIGN COMPETITION IN CANADA.

*Chem. and Druggist, Sept. 25, 1897.*

The following extracts from the statistics appended to the recent Blue Book relate to the most important chemicals:—

**Bleaching Powder.**—Britain is squeezing out America, but France is appearing as a competitor. The development of alkali manufacture in the States since 1894, however, may again have altered the proportions in the past three years. In 1884 Canada bought 21,305 *dols.* worth in the States and 36,816 *dols.* from Britain; in 1894 the States supplied her with only 5,995 *dols.* worth, and the mother country with 43,877 *dols.* Other nations are practically out of this business.

**Borax.**—In this article Britain has taken complete possession of the field. In 1884 Canada bought 15,000 *dols.* worth from the States and the same amount from Britain. Five years afterwards the proportions were 12,341 *dols.* and 5,108 *dols.*; and in 1894 Britain supplied 35,887 *dols.*, the States only 2,303 *dols.* This is a growing business, and worth watching.

**Bottles (including Carboys and Demijohns).**—Defeat of the States by Germany, with the incidental out-squeezing of Britain and France. Belgium and Austria are also getting more than a look-in in the Canadian bottle-trade. Here is the proof:—

	1884.	1889.	1894.
From United Kingdom .....	<i>Dols.</i> 86,027	<i>Dols.</i> 26,134	<i>Dols.</i> 22,215
" U.S.A. ....	253,232	59,174	77,997
" Germany.....	22,742	49,370	95,214
" France.....	9,973	3,163	3,616

**Acids.**—Britain has lost a little ground during the past decade. The importation of many acids, such as sulphuric, has ceased almost entirely since 1884, because Canada now manufactures these goods for herself; but the principal loser by this process of emancipation has been the United States, not Britain. In acetic acid the total importation of Canada has fallen from 19,101 *dols.* in 1884 to 9,228 *dols.* in 1894. The share of Britain has decreased from 3,984 *dols.* to 1,354 *dols.*, of U.S.A. from 4,140 *dols.* to 479 *dols.*

But Germany has kept her lead—7,900 *dols.* in 1884, 7,395 *dols.* in 1894. Of sulphuric acid Canada imported 18,033 *dols.* worth in 1884, and only 1,648 *dols.* in 1894.

**Alum and Aluminous Cake.**—The balance of imports has been shifted from Britain to the United States. Here are the figures:—

	1884.	1889.	1894.
From United Kingdom .....	<i>Dols.</i> 17,329	<i>Dols.</i> 16,538	<i>Dols.</i> 11,572
" U.S.A. ....	5,137	5,428	13,507
" Germany.....	..	1,431	319

Of late years Belgium has also shipped parcels of alum.

**Cream of Tartar.**—The subjoined figures speak for themselves:—

	1884.	1889.	1894.
Great Britain.....	<i>Dols.</i> 57,683	<i>Dols.</i> 94,392	<i>Dols.</i> 56,567
United States .....	24,192	14,421	15,573
France .....	46,639	50,432	50,554
Total .....	128,514	159,245	103,134

**Phosphorus.**—Britain holds her own in this trade, while America is falling off. No other countries participate in the business, but as time goes on Canada will probably manufacture all her own requirements. The figures are:—

	1884.	1889.	1894.
From United Kingdom .....	<i>Dols.</i> 9,058	<i>Dols.</i> 7,969	<i>Dols.</i> 8,308
" U.S.A. ....	3,092	122	1,059

**Potashes.**—Britain is rapidly losing ground in this department, but it must be added that the imports of potash salts into Canada are decreasing all round. Of saltpetre the Dominion imported 38,219 *dols.* in 1884, but only 16,978 *dols.* in 1894. In the former year Britain supplied 19,950 *dols.*, Germany (together with Holland, whose saltpetre exports must have been of German origin), 17,879 *dols.* worth. In 1894 the figures were:—Britain, 3,662 *dols.*; United States of America, 4,081 *dols.*; Germany, 9,235 *dols.* In crude muriate and bichromate of potash we are also losing trade, and Germany is stepping in. The figures were:—

	1884.	1889.	1894.
From United Kingdom .....	<i>Dols.</i> 35,898	<i>Dols.</i> 16,750	<i>Dols.</i> 15,290
" U.S.A. ....	2,993	12,600	8,278
" Germany.....	..	..	5,494

Other potash salts are very little imported.

**Soda-salts.**—In the department of soda-salts Britain has always held the lead among the providers of Canadian requirements. But it may be noted with satisfaction that while the annual imports of the Dominion in this branch of business are growing slowly, they are more and more falling into British hands. The United States are distinctly losing ground. Look, for instance, at the figures relating to soda-ash, nitrate, caustic, crystals, and silicate:—

	1884.	1889.	1894.
From United Kingdom .....	<i>Dols.</i> 204,128	<i>Dols.</i> 204,374	<i>Dols.</i> 241,893
" U.S.A. ....	114,446	55,254	43,484
" other countries .....	..	20	1,205

And in bicarbonate of soda we have the field practically to ourselves:—

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
From United Kingdom .....	27,295	26,143	11,919
" U.S.A. ....	1,511	2,119	1,737

No other countries compete.

**Soaps.**—The Canadian Customs divide soaps in five great classes, which, in order of value, are as follows:—(1) Soap powders, sapollo, &c.; (2) Perfumed or toilet soaps; (3) Common brown and yellow soap; (4) Castille and white soap; and (5) Common soft soap, saddlers' soap, and silver soap. In Class 1 the U.S. hold the field. In 1894 they provided 49,723 dols. worth out of a total of 53,517 dols. Britain supplying the rest. This is a pity, for this soap-powder business has practically sprung up in the last 10 years. But in toilet soap Britain leads, and is steadily gaining ground, rather at the expense of the United States. The figures are interesting:—

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
From United Kingdom .....	14,109	15,296	19,896
" U.S.A. ....	25,069	20,196	21,323
" France .....	2,007	899	1,588

There are practically no other competitors.

In Class 3 (common soaps) Britain has completely taken the place of the United States, as will be seen by the following figures:—

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
From United Kingdom .....	9,701	6,874	35,220
" U.S.A. ....	28,067	6,397	3,219

Class 4, Castile soap, is in the hands of France, Marseilles being the headquarters of this industry, which depends upon cheap olive oil for its success. The imports are increasing, and in 1894 were worth 17,470 dols. Class 5 is a small one, but here also Britain is displacing the States:—1884, United States of America, 4,366 dols.; Britain, 498 dols. 1894, United States of America, 1,240 dols.; Britain, 1,889 dols. The total soap imports of Canada in 1894 were worth about 169,000 dols.

**Instruments.**—There is a rapidly-growing import business in surgical, optical, and philosophical instruments, but in these branches, in which ten years ago Britain led the way, she has been hopelessly outstripped by the United States and Germany. The figures are melancholy reading:—

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
Surgical instruments:—			
From United Kingdom ...	6,875	12,678	8,099
" U.S.A. ....	5,558	11,578	25,596
" Germany .....	..	1,084	10,020
" France .....	..	1,851	1,379

and in optical instruments (including spectacles, microscopes, and telescopes) our discomfiture is still worse:—

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
From United Kingdom .....	23,277	18,287	16,762
" U.S.A. ....	29,289	30,183	69,608
" Germany .....	1,729	4,011	8,767
" France .....	10,639	16,339	16,985

In india-rubber goods much the same sort of thing is going on. Our defeat in this branch of business is nothing short of a disgrace to this country. We held the market

when it was small. Now that it is worth 200,000 dols. a year at least, we have been practically thrown out.

**Patent Medicines.**—The imports of patent medicines into Canada equal in value those of surgical and philosophical instruments. But while we have lost our grip of the last-named business, the British patent medicine still has a fair hold on the affection of the Canadians, though it yields the palm to the American nostrum. Of patent medicines the imports were:—

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
From United Kingdom .....	27,386	43,078	36,740
" U.S.A. ....	113,713	118,199	141,620
" France .....	4,419	14,121	11,383

## GENERAL TRADE NOTES.

### THE CANADIAN LEATHER INDUSTRY.

*Bd. of Trade J., Sept. 1897, 354.*

The *Monetary Times* (Toronto) states that the export of Canadian leather is a trade of recent growth, but if it continues to develop as it has done in the past 10 years, it will soon become of national importance. The annual value of sole and upper leather exported from Canada during the last decade is as follows:—

Years.	£	Years.	£
1887	92,000	1892	211,000
1888	62,000	1893	180,000
1889	139,000	1894	328,000
1890	151,000	1895	265,000
1891	181,000	1896	397,000

### THE CHILIAN NITRATE INDUSTRY.

*Bd. of Trade J., Sept. 1897, 350.*

According to the *Chilian Times* the production of nitrate in 1896 amounted to 23,832,434 quintals, and the exportation amounted to 24,066,189 quintals. The principal countries to which nitrate is exported from Chile are Germany, United Kingdom, France, United States, and Holland.

The following table shows the world's consumption of nitrate for the last seven years:—

Years.	Spanish Quintals.	Years.	Spanish Quintals.
1890	20,244,523	1894	22,750,901
1891	20,969,785	1895	23,858,193
1892	20,194,852	1896	24,604,150
1893	20,453,496		

Consequently, since 1891 to 1896 there has been an increase in consumption over 1890 of 4,359,627 quintals, or close upon 200,000 English tons.

### MINERAL INDUSTRY OF BOSNIA-HERZEGOVINA IN 1896.

*Bd. of Trade J., Sept. 1897, 348.*

The *Revue d'Orient* states that, according to official returns, the mineral production of Bosnia-Herzegovina in 1896 was as follows:—

	1896.	1895.
	Tons.	Tons.
Copper ore .....	4,003	1,776
Iron ore .....	23,213	12,735
Chrome ore .....	442	706
Manganese ore .....	6,821	8,145
Lignite .....	222,724	195,496
Copper .....	206	105
Iron, raw .....	10,120	2,569
Cast goods .....	1,039	1,080
Salt (kitchen) .....	13,740	12,738

## THE PRODUCTION OF PETROLEUM.

*Id. of Trade J., Sept. 1897, 267.*

The following particulars, derived from various official and other sources, show the state of the industry in some of the principal petroleum-producing countries:—

**Russia.**—According to a recent report of H.M. Consul at Batoum, the total quantity of naphtha produced by the wells of the oil fields in the neighbourhood of Baku during the past year was in excess of that of the year preceeding; the figures being 6,229,060 tons for 1896, against 6,085,131 tons in 1895, or an excess for 1896 of 143,629 tons.

The quantity of crude oil produced by the flowing wells was 1,403,218 tons in 1896, against 1,817,704 tons in 1895; and by pumping wells 4,825,842 tons in 1896, as compared with 4,267,727 tons in 1895.

The naphtha-producing territories at Grozni, in the Northern or Tis-Caucasus, in Galicia, Java, Japan, and Peru, are slowly but surely coming into prominence. Hitherto the Baku mineral oil industry has had to compete with only one serious rival, *i.e.*, America, but now the following fresh factors must be counted with, namely:—

The discovery of oil in the district of Grozni, which took place in 1893, and is annually assuming wider proportions. It is stated that there are at present seven firms at work there, obtaining oil in unlimited quantities, which, although it may probably not be of such good quality for refining purposes as the oil produced by the wells on the shores of the Caspian Sea, is nevertheless sufficiently good for burning as fuel.

The extended development of the mineral oil industry in Galicia has had the effect of bringing about a sensible decrease in the quantity of distillate shipped from Batoum to Austria-Hungary during the past year, which circumstance may eventually have the same effect on the markets in Germany, where, according to reports, it is proposed to increase the import duties on mineral oils reaching that country from Russia and America, and to draw the supplies for home consumption in the shape of the crude material from Galicia, erecting in Germany the necessary works for refining purposes.

**Dutch East Indies.**—There is increased production of petroleum in Java, and the supplies from that island to Chinese ports are steadily increasing, although it is stated that the kerosene is of inferior quality.

For the working of Javanese petroleum, a company was formed at Amsterdam in March last as a successor to the Dordt'sche Petroleum Maatschappij, which was organised in 1887 and reorganised in 1890.

A recent issue of *Kuhlow's* reports that this company commenced operations in the district of Djaba Kota, residency of Soerabaja, and secured leases and concessions for the best oil territories on the island. It also took an interest in extensive oil lands at Langkat and Palembang on the island of Sumatra, and at Koetei on the island of Borneo.

Besides extending their operations in the residency of Soerabaja, the company, after having placed their first petroleum on the market in 1889, succeeded, in 1893, in opening up the oil fields in the residency of Renbang, which proved highly productive. The oil found there is of excellent quality, and the output permitted a rapid increase in the production of illuminating oil.

The Dordt'sche Petroleum Maatschappij intends in the first place to supply the Java and Madura markets, the consumption of which increased from about 2,500,000 cases in 1889 to 3,600,000 cases in 1896. Of the latter, 1,250,000 cases were supplied by the Dordt'sche Petroleum Maatschappij. This shows that the company can safely treble its productions before it needs to look around for outside markets. The transport facilities are very good. The company controls a fine system for handling its products, consisting of pipe lines, tank cars, reservoirs, and casing houses, which are distributed all over the island.

Statistics of the last eight years show that the Javanese production of illuminating oil has increased from 8,000 cases in 1889 to 1,250,000 cases in 1896, and the net earnings of the company from 36,697 florins to 1,923,611 florins. The production for January 1897 amounted to 108,007 cases,

as against 87,577 cases for January 1896. The capital stock of the Dordt'sche Petroleum Maatschappij is 15,000,000 florins, one florin being about equal to 1s. 8d.

**Roumania.**—Mr. A. Percy Bennett, H.M. Acting Consul at Galatz, sent to the Foreign Office, in November 1896, a special report on the petroleum industry of Roumania, in which he says that it may be taken for granted that petroleum exists in abundance in that country.

From Turn-Severin or thereabouts, on the western frontier of Roumania, the petroleum zone can be traced at the foot of the Carpathian Hills, skirting them in their course through the country towards Bukovina and Galicia, on the north-east. Petroleum is there found in the paludinous plicocene and in the miocene formations; its existence is evident, not only by its traces on the surface, but by other indications, such as its smell and its gases. Along the whole length of the zone mentioned may be seen primitive workings of the mineral in the shape of comparatively shallow hand-dug wells. These wells, producing small quantities of oil, are scattered over an area of from 10 to 15 kiloms. From end to end of the zone there are five principal centres at which the workings have been concentrated, and at these centres have been found, collected in pockets near the surface, the largest quantities of oil of the first stratum yet discovered. These centres are:—

1st. Olt Valley, in the vicinity of Rimnic-Valeea (Valeea District).

2nd. Dimbovitza and Talamitza Valleys, in the vicinity of Tirgu-Vestei (Dimbovitza District).

3rd. Prahova and Teleagen Valleys, north of Ploiesti (Prahova District).

4th. Buzau Valley, north of Buzau (Buzau District).

5th. Trotus and Tazlau Valleys, between Tirgu-Oena to the south and Bacau to the north (Bacau District).

According to several writers, petroleum is to be found not only in the above-mentioned zone, but also in the whole of the plains down to the Danube, which would embrace a zone of, say, 100 kiloms. in width. This assertion is, to a certain extent, verified by certain and manifest signs of the existence of petroleum, but it is not known at what depth even the first stratum may be met with, as no borings for oil have ever been made in the plains, and the water wells sunk by hand there have not, up to the present, touched any oil-pocket however small. So far, at the five centres referred to above, only the first stratum has been worked to any extent. These centres comprise about 50 borings, and, say, 500 hand-dug wells. The deepest successful boring only reaches about 300 metres, and whilst the majority of the hand-dug wells range from 60 to 120 metres, none of them go below 200 metres.

The output of crude oil from these borings and wells for the year 1894-95 reached 80,000 tons.

The Consul, in his report, adds that, though petroleum has been worked in Roumania for about 25 years, yet considering the small quantity now extracted, and taking into account the extensive zone in which distinct evidence of its existence is to be met with, it is evident that the Roumanian petroleum industry is at present only in its infancy.

**United States.**—The year 1885 seems to have marked a new era in the history of petroleum. The importance of the Trenton limestone as an oil producer in the United States was first recognised at this time, and this year marks the discovery of the Lima (Ohio) and the Indiana fields. From the Lima field alone was derived more than one-third of all the oil produced in the United States in 1889.

The following table, taken from the report of the United States Secretary of the Interior for 1896, shows the production of crude petroleum in the United States from the year 1885 to 1895, in barrels of 42 Winchester gallons each:—

Years.	Barrels.	Years.	Barrels.
1885	21,858,785	1891	54,291,980
1886	28,664,841	1892	50,569,136
1887	28,283,483	1893	48,412,666
1888	27,612,025	1894	49,314,516
1889	35,163,513	1895	52,983,526
1890	45,822,672		

Since the beginning of operations at Titusville, Pennsylvania, in 1859, the enormous total of 709,713,403 barrels of crude petroleum have been produced in the United States. By far the largest portion of this has been produced in what is known as the "Pennsylvania and New York oil fields," these fields producing alone 516,657,260 barrels of the total of 709,713,403 barrels, or nearly 73 per cent. Ohio has produced 133,343,773 barrels, and West Virginia 37,179,604 barrels; California and Colorado have produced respectively 6,683,901 and 4,188,325 barrels, while Indiana, which did not figure as a producer of petroleum until 1883, has produced 11,341,664 barrels, more than one-third of which was produced in 1895.

**Peru.**—In a recent report to the Foreign Office by Her Majesty's Consul at Callao, it is stated that the petroleum industry in the north of Peru originated some 30 years ago, oil having been discovered by drilling for water on the Mancora estate, near Payta. During that period six different undertakings have been started, but so far without giving satisfactory results. Two kerosene factories exist on this coast; the kerosene produced gives a dull light, smokes, and cannot bear comparison with American kerosene, which fetches from 8 to 9 soles the case, whilst the former has to be sold at from 2 soles 50 c. to 3 soles the ease of 10 gallons, and only serves for street lighting. From 4,000,000*l.* to 5,000,000*l.* have been spent on the several undertakings, without producing in any single case a fair return. Hundred of wells have been sunk, some resulting in flowing, others in pumping wells, oil being found at a depth varying from 250 to 600 feet, but all have run dry after a very short flow. Experts from the United States have carefully examined the land north and south of Payta, and have given it as their opinion that, in spite of abundant surface indications all over the district, no oil of any importance is likely to be found.

The *Manufacturer* (Philadelphia) states that the London and Pacific Petroleum Company, at Negritos, 45 miles north of Payta, has a pipe line from its wells at Negritos, and pumps the oil a distance of six miles, to Talara, on the coast, where its refinery is located, and from which point it ships its product. This company has produced 8,000,000 barrels of crude oil in the last six years, and now has a production of 200 barrels per day. One of its best wells produced 500 barrels a day six years ago, and is still making 45 barrels a day. There is but little gas in the field, and in consequence oil is used for fuel in operating the wells. Salt water is troublesome unless the wells are kept pumping continuously.

The right to drill must be secured by grant from the Peruvian Government, as it retains the mineral right in all the land in Peru. American machinery is used almost exclusively.

#### THE OZOKERITE MONOPOLY (GALICIA).

*Chem. Zeit.* 21, [44], 439.

At present the syndicated mine owners' control, either by ownership, option, or contract, the greater part of the shafts in the Boryslaw, Truscawice, Dwinia, and Starunia districts, and produce sufficient ozokerite to supply the demand, the few outsiders being unable to produce enough to satisfy the requirements of any ceresin works, most of whom are, moreover, under engagement to buy from the syndicate alone. A few of the ceresin makers, having mines of their own, were able to make better terms than the bulk, who have to put up, as best they may, with the increased rates for raw material. The Austro-Hungarian Länder Bank, which is interested in the association, is said to be endeavouring to obtain a concession for forming a share company, to carry on the work of the syndicate.

—C. S.

#### DENATURING OF ACETATES.

*Chem. and Druggist*, Aug. 28, 1897, 359.

A tax of 62 frs. 50 cents is levied in Paris upon every 100 kilos. of vinegar, with a corresponding amount upon acetic acid or acetates, which thus becomes a considerable obstacle in many industries. It is now proposed to admit the acetates and acid duty free, provided they are denatured so as to unfit them for domestic use or for conversion into

vinegar. Altogether six methods of denaturing are suggested, viz., the addition of (a) 1 per cent. of Methylene Blue, ferric nitrate, copper sulphate, Rhodamine, or Victoria Blue; (b) 2 to 3 per cent. of copper acetate; (c) 3 per cent. of vitriol; (d) 5 grms. of soluble Naphthol Black, Blue, Red, or Yellow, per litre of acetic acid; (e) 7 grms. of arsenic per litre; or (f) 2 grms. of lead acetate per litre.

### BOARD OF TRADE RETURNS.

#### SUMMARY OF IMPORTS.

Articles.	Month ending 31st August	
	1896.	1897.
	£	£
Metals.....	1,836,201	1,572,652
Chemicals and dyestuffs .....	411,899	360,704
Oils.....	642,811	594,905
Raw materials for non-textile industries.	5,936,984	5,635,210
Total value of all imports ....	32,480,473	33,371,385

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

### 1.—PLANT, APPARATUS, AND MACHINERY.

#### APPLICATIONS.

18,950. P. Boimare. Improvements in smokeless furnaces. Aug. 16.

19,077. W. Astley. Chemical boiling-down pans expansion trough bottoms. Aug. 18.

19,196. E. Stephenson. Improvements in condensers. Aug. 19.

19,249. A. Fidler. Improvements in and relating to precipitating tanks and the like. Aug. 20.

19,344. T. Swift and G. H. Swift. A liquid composition for the removal and prevention of scale and protection from corrosion on inside of boilers. Aug. 21.

19,372. A. J. Boulton.—From P. Muratel, France. Improvements in filtering apparatus. Aug. 21.

19,405. A. Cottier and J. Jaquetin. System of hydro-extractor. Aug. 23.

19,468. F. Turnbull. Apparatus for washing coal, coke, and similar materials and minerals. Aug. 24.

19,718. T. R. Berkley. Improvements in refuse-consuming furnaces. Aug. 26.

20,218. J. Weichmann. Improvements in distilling apparatus. Sept. 2.

20,349. H. J. Demuth, E. N. Perkins, and J. T. Dade. Improvements in brine-evaporating apparatus. Sept. 4.

21,285. J. L. Collier. See Class XVI.

21,311. G. T. Holloway. A new or improved laboratory gas furnace. Sept. 17.

21,359. A. Barr and W. Stroud. Improvements in apparatus for the production of high vacua. Sept. 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1896.

19,039. W. Defries. Filtering apparatus. Sept. 1.

22,169. W. H. Strype and J. A. Mason. Improvements in metal hampers or baskets for carboys. Sept. 15.

23,189. A. S. Barham and L. de Wittenbach. Improvements in apparatus for sterilising milk and other liquids. Sept. 8.

23,379. H. F. Stanley and The Farringdon Works, Ltd. Improvements in apparatus for refrigerating air and other gases. Aug. 25.

23,723. T. C. Taylor and J. E. Tolson. Improvements in retorts for carbonising machines. Sept. 8.

24,405. R. M. McDougall. Improvements in the packing of the tubes in the rectifiers of Coffey's distilling apparatus. Sept. 15.

28,728. P. E. Placet. Improvements in the lining of crucibles and furnaces. Sept. 22.

1897.

17,356. W. G. Heys.—From J. Klein, of the Maschinen und Armaturfabrik vormals Klein, Schanzlin, and Becker, Germany. Improvements in apparatus for cooling liquids. Sept. 1.

18,578. H. Hirzel. An improved absorption apparatus for absorbing gases in liquids. Sept. 22.

#### II.—FUEL, GAS, AND LIGHT.

##### APPLICATIONS.

18,904. J. W. Searth and W. A. Thornton. Improvements in apparatus for the generation of acetylene gas, and like purposes. Aug. 16.

18,907. A. Denich. Portable apparatus for producing acetylene gas. Aug. 16.

18,971. J. R. Wigham. Manufacturing acetylene gas from calcium carbide. Aug. 17.

18,978. C. E. Billing. Improvements in the method of and means for the economical use of gas for lighting purposes. Aug. 17.

18,989. H. Maxim and W. H. Graham. Method and apparatus for the production of calcium carbide; applicable also to other purposes. Aug. 17.

19,149. W. E. Koehs. Improvements in coke ovens and in machinery in connection therewith. Complete Specification. Aug. 19.

19,319. E. Barnard. Improved apparatus for generating and supplying acetylene or other gases. Aug. 20.

19,411. H. J. Bell and The Niagara Falls Acetylene Gas Machine Company, Ltd. Apparatus for the production and storage of acetylene gas. Complete Specification. Aug. 23.

19,437. A. A. Flürscheim. Manufacture of "mantles" and the like for incandescent gas lights. Aug. 23.

19,442. J. Y. Johnson.—From C. Bartelt and F. Bartelt, Germany. Treatment or preparation of oxygen to bring it into a form suitable for internal application. Aug. 23.

19,590. F. M. Mooney. Treatment of the oxide of iron used for the absorption of sulphuretted hydrogen in the purification of illuminating or other gases or otherwise. Aug. 25.

19,615. O. Münsterberg. Improvements in apparatus for the manufacture of acetylene gas. Aug. 25.

19,765. A. A. Flürscheim. Manufacture of "mantles" or the like for incandescent gas lights. Aug. 27.

19,798. J. H. H. Duncan and G. Bourrelly. Method and apparatus for producing flame and light by the use of hydrocarbons. Aug. 27.

19,823. T. Thorp and T. G. Marsh. Improvements in apparatus for the production of acetylene from calcium carbide and water. Complete Specification. Aug. 28.

19,887. L. G. Harris. Manufacture of gas from garbage and other refuse. Aug. 28.

19,889. F. J. Lothammer. Method of and apparatus for carburising air. Complete Specification. Aug. 28.

19,951. L. Chambault. Method and apparatus for generating and burning acetylene gas, chiefly designed for use on velocipedes, autocars, boats, and the like. Complete Specification. Aug. 30.

20,011. E. J. Dolan. Improvements in acetylene gas generators. Date applied for March 19, 1897, being date of application in United States. Complete Specification. Aug. 31.

20,051. F. Rhind. Improvements in gas generating. Date applied for Feb. 27, 1897, being date of application in United States. Complete Specification. Aug. 31.

20,052. F. Rhind. Improvements in gas generating lamps. Aug. 31.

20,142. F. A. Keiffer. Improvements in apparatus for the automatic supply of carbide of calcium in the production of acetylene gas. Date applied for Feb. 4, 1897, being date of application in France. Sept. 1.

20,184. W. Dancer. Improvements in the production of gas for illuminating and heating purposes and of certain bye-products. Sept. 2.

20,225. I. Freudenthal. An improved solution or fluid for impregnating incandescent bodies. Complete Specification. Sept. 2.

20,319. E. Saizenberg. Improvements in incandescent gas lighting. Complete Specification. Sept. 3.

20,381. J. A. Sinclair and E. R. Powell. Improvements in means or apparatus for use in the production, storing, and cooling of acetylene gas. Sept. 4.

20,464. A. Chauvel and G. Ménétrier. Improvements in the manufacture of fuel cakes or blocks for industrial and domestic purposes. Sept. 6.

20,532. C. Petit and G. Gavrel. Improvements in or relating to apparatus for the manufacture of acetylene gas. Date applied for March 8, 1897, being date of application in France. Sept. 7.

20,537. F. Windham and E. Fry. Portable lamps for producing gas from carbide of calcium. Sept. 7.

20,571. O. Kahns. Process and apparatus for the production of carburetted air for incandescent gas light. Complete Specification. Sept. 7.

20,572. H. H. Leigh.—From H. Abraham and L. Marmier, France. Generating of ozone and apparatus therefor. Sept. 7.

20,574. G. Lebrun and F. Cornaille. A burner for acetylene and other gases rich in carbon. Date applied for March 4, 1897, being date of application in France. Complete Specification. Sept. 7.

20,586. J. Dymond. Apparatus for producing luminous water-gas. Sept. 11.

20,987. F. S. Thorn and C. Hoddle. Acetylene generator for lighting cycle and other vehicle lamps. Sept. 13.

21,094. G. B. Ellis.—From N. Lepage and L. M. Maisonnier, France. Improvements in apparatus for producing acetylene gas. Sept. 14.

21,114. H. R. Bean and H. Ringwood. Improvements in apparatus for the generation of acetylene and other gases. Sept. 14.

\* See Note (\*) on previous page.

21,115. T. C. Palmer, of the firm of W. J. Fraser and Co. See Class XII.

21,150. J. Carter. The Carter incandescent gas light mantle and chimney protector. Sept. 15.

21,346. W. A. Thornton. Improvements in or relating to apparatus for the generation of acetylene gas and like purposes. Sept. 17.

21,347. W. A. Thornton. Improvement in or relating to apparatus for the generation of acetylene gas and like purposes. Sept. 17.

21,372. E. C. Chardin. Improvements in apparatus for producing acetylene gas. Sept. 17.

21,464. J. Windmüller, of the firm of Windmüller and Co. An improved device for producing and burning acetylene gas. Sept. 18. Complete Specification.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

11,109. C. Weygang. Improvements in application of artificial fuel. Aug. 25.

19,044. A. F. de Villejégué, V. Fournier, and G. Shenton. Apparatus for extracting oxygen from the air. Sept. 8.

19,521. J. S. V. Bleford. Apparatus for lighting and heating by means of petroleum vapour. Sept. 8.

20,084. W. W. Hughes and S. Willson. Treatment or utilisation of peat and its products. Sept. 8.

20,090. E. Chesnay and L. Pillion. Apparatus for generating and storing acetylene gas. Sept. 1.

20,156. P. R. de F. d'Humy. Manufacture of fuel. Sept. 15.

20,254. E. Chesnay and L. Pillion. Apparatus for generating and storing acetylene gas. Sept. 8.

20,713. J. L. Waldapfel. Improvements in burning liquid hydrocarbons in conjunction with an incandescent hood or mantle to produce an incandescent oil burner. Sept. 22.

22,194. P. Jebsen. Process for carbonisation of peat by electric heating. Aug. 25.

22,828. C. W. S. Crawley, A. Soames, and C. V. Drysdale. Method of obtaining a continuous supply of gas or vapour under pressure. Sept. 15.

23,006. A. Quentin. Improvements in and relating to incandescence bodies for heating purposes. Sept. 22.

23,483. F. B. Grundy and J. Moeller. Improvements in the manufacture of appliances for effecting self-lighting of gas. Sept. 1.

23,752. W. J. Mackenzie. Improvements in apparatus for generating acetylene gas. Sept. 15.

24,611. A. Kay. Improvements in portable apparatus for generating and storing acetylene gas. Sept. 22.

25,236. E. Chesnay, L. Pillion, and C. Bertolus. Apparatus for automatically producing and storing acetylene. Sept. 15.

25,488. A. Fournier. Apparatus for the production of acetylene gas. Sept. 22.

25,827. E. Skriwan. Improvements in the method of and means for binding mantles for incandescent lights. Sept. 22.

1897.

1777. L. Denayrouze. An improvement in burners for incandescent gas lights. Sept. 1.

9714. U. Kesselring. An improved apparatus for the manufacture of acetylene gas. Sept. 1.

12,021. H. Freise. Process for manufacturing a smokeless inflammable wick. Sept. 8.

14,091. E. Jimeno. Improvements in or connected with gas holders for acetylene and other lighting gases. Sept. 8.

15,963. A. Kiesewalter. Improvements in incandescent mantles. Sept. 15.

16,145. A. George. Improvements in the manufacture of briquette fuel. Sept. 8.

16,195. G. C. Marks.—From A. F. Bowers, France. Improvements in apparatus for the generation of acetylene gas. Sept. 8.

17,021. E. Godin. Improvements in acetylene gas generators. Sept. 1.

18,005. W. P. Thompson.—From A. Julien, Belgium. Improvements in and relating to apparatus for producing heating or lighting gas by the aid of volatile hydrocarbons. Sept. 22.

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, &c.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

23,649. J. Meikle. Improvements in obtaining benzene, toluene, and other products from mineral oils and liquid tars. Sept. 15.

#### IV.—COLOURING MATTERS AND DYES.

##### APPLICATIONS.

18,990. T. R. Shillito.—From J. R. Geigy and Co., Switzerland. Production of paradinitrobenzylsulphonic acid and of new colouring matters or dyes. Aug. 17.

19,498. T. R. Shillito.—From J. R. Geigy and Co., Switzerland. Manufacture of aldehydonaphtholsulphonic, aldehydonaphtholcarboxylic, and aldehydonaphtholsulphocarboxylic acids and of new blue and green colouring matters or dyes therefrom. Aug. 24.

19,622. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Manufacture of anthraquinone dyestuffs. Aug. 25.

19,634. O. Imray.—From H. Schneider, Germany. Manufacture of a new amido base and new direct-dyeing polyazo dyestuffs therefrom. Aug. 25.

19,749. P. Cannell-Bunn. Manufacture of colours. Aug. 27.

19,783. R. Webb. Improvements in security inks. Complete Specification. Aug. 27.

19,785. G. B. Ellis.—From La Société Chimique des Usines du Rhone anciennement Gillard P. Monnet et Cartier, France. Production of colouring matters and intermediate products. Aug. 27.

19,790. C. E. Anquetel. A new or improved ink. Aug. 27.

19,904. I. Levinstein and Levinstein, Ltd. Production of colouring matters. Aug. 30.

19,994. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. Production of new colouring matters related to the rhodamine series. Aug. 31.

20,125. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig, Germany. Manufacture of dyestuff directly dyeing cotton black. Sept. 1.

20,278. T. R. Shillito.—From J. R. Geigy and Co., Switzerland. Manufacture of new polyazo colouring matters or dyes. Sept. 3.

20,333. W. H. Claus, A. Rée, and L. Marchlewski. Production of new derivatives of alkyl-hydroxy-para-amidobenzenes. Sept. 4.

20,410. E. S. Wilson and E. Stewart. Improvements in the production of dyes. Sept. 6.

20,649. H. E. Newton.—From Farbenfabriken vormals Friedrich Bayer and Co., Germany. The manufacture or production of colouring matters derived from anthraquinone. Sept. 8.

20,827. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig, Germany. Manufacture of new alizarine dyestuffs. Sept. 10.

21,060. I. Levinstein and Levinstein, Ltd. Manufacture or production of colouring matters. Sept. 14.

21,297. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of new black colouring matters derived from naphthazarine. Sept. 15.

21,316. I. Levinstein and Levinstein, Ltd. Manufacture or production of colouring matters. Sept. 17.

21,598. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. See Class XIII.

21,399. A. G. Green and A. R. Wahl. Improvements in the preparation of colouring matters for cotton. Sept. 17.

21,451. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of blue to green dyestuffs soluble in water. Sept. 18.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,197. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Improvements in the production of colouring matters. Sept. 8.

21,211. W. Clark. From C. H. Boehringer and Sohn. Process of preparing solutions of artificial and natural colouring matters for dyeing and printing purposes. July 7.

21,134. S. Pitt.—From L. Cassella and Co. Introduction of a blue dyestuff suitable for dyeing wool. Sept. 15.

#### V.—TEXTILES, COTTON, WOOL, SILK, ETC.

##### APPLICATIONS.

18,928. F. Vanoutryve. Process and apparatus for treating cotton and other vegetable fibre, either in the woven or filamentous condition, for imparting lustre thereto. Aug. 16.

19,256. W. Baldwin. Improvements in the process of and means for sizing yarn. Aug. 20.

20,222. W. Grandage and H. Grandage. Improvements in or relating to the treatment of cotton and other yarns, and in apparatus therefor. Sept. 2.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

20,714. R. Thomas and E. Prevost. Improvements in mercerising vegetable fibrous substances. Sept. 8.

20,737. C. O'Brien and J. Shearer. Method for improving the colour of raw jute fibre. Sept. 22.

20,960. O. Junge.—From S. B. Allison. Improvements in machines for separating and cleaning the fibres of plants of every description. Sept. 1.

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

##### APPLICATIONS.

19,095. H. Seidel. Improvements in the mordanting of fibrous materials preparatory to dyeing such materials. Aug. 17.

19,260. W. Hadfield, J. J. Sumner, and H. Hadfield. Improvements in method and means for bleaching textile fabrics. Aug. 20.

19,269. J. O. Barlow. Improved chemical process for the dyeing of vegetable and animal fibres with reduced indigo. Aug. 20.

19,592. E. Laube and H. Resch. Improvements in method and apparatus for bleaching and treating textile fibres and yarns. Aug. 25.

20,210. B. Willeon.—From Badische Anilin and Soda Fabrik, Germany. Improvements in the production of discharge effects on indigo. Sept. 2.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

23,635. E. Makin, jun. Improvements in connection with kiers and like vessels for bleaching, dyeing, and similarly treating textile materials, yarns, and fabrics. Sept. 15.

23,718. H. Bentley. Improvements in apparatus for scouring and dyeing hanks of yarn or fibrous material. Sept. 15.

23,741. A. Liebmann and W. Kerr. Improvements in the methods or means for mordanting yarns, threads, fabrics, and other materials composed of fibres having a vegetable origin. Sept. 15.

1897.

14,319. V. Floquet and L. Bonnet. Improvements in bleaching and disinfecting fibrous materials, and apparatus for that purpose. Sept. 1.

#### VII.—ACIDS, ALKALIS, AND SALTS.

##### APPLICATIONS.

19,107. F. M. Lyte, O. J. Steinhart, and W. H. Wickham. Production of ammoniac phosphates. Aug. 18.

19,512. J. W. Keneval, C. A. Spofford, and J. H. Mead. Means for manufacturing carbides. Complete Specification. Aug. 24.

20,346. A. Haaz. Improvements in apparatus for making vinegar. Sept. 4.

20,567. W. Muir. A new alkaline compound, a method of forming it, and a description of some of its uses. Sept. 7.

21,073. J. Reich. Method of transforming silico fluorides and boron fluorides into corresponding fluorides or fluorine compounds. Complete Specification. Sept. 14.

21,178. J. Hargreaves. Improvements in and relating to the treatment of solutions of carbonates of soda resulting from electrolysis of chloride of sodium, and in apparatus applicable for use therein. Sept. 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

18,468. I. Jurin. Proceeding for cleaning carbonic acid. Aug. 25.

18,589. J. Hargreaves and R. Armstrong. Manufacture and treatment of detergent and bleaching compounds, and apparatus employed therein. Sept. 1.

20,423. P. Jensen.—From H. Cappelen and D. Cappelen. Improvements in pumping apparatus for chlorine gas and the like. Sept. 15.

22,512. M. Schwab. Improved method of and apparatus for concentrating sulphuric acid. Sept. 15.

22,792. J. W. Chenhall. Improvements in the manufacture of bleaching compounds. Sept. 15.

23,614. J. W. Weston and T. I. Weston. Improvements in the manufacture of salt from brine, and in apparatus therefor. Sept. 8.

#### VIII.—GLASS, POTTERY, AND ENAMELS.

##### APPLICATIONS.

19,003. H. Brooke and J. C. Groat. Apparatus for the manufacture of glass. Complete Specification. Aug. 17.

19,303. W. Preston. Improvements in glass annealing furnaces or leers. Aug. 26.

19,493. C. C. Hartung. Making plate glass. Complete Specification. Aug. 24.

20,388. J. B. Vernay. An automatic machine for the manufacture of bottles and other articles of glass. Date applied for Feb. 5, 1897, being date of application in France. Complete Specification. Sept. 4.

20,399. W. Boulton. Improvements in or applicable to filter presses for treating potter's clay and other substances. Sept. 4.

20,414. W. Thomson. Improved glass tiles. Sept. 6.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

24,033. J. Jacques, W. E. McCalla, and J. Nicholson. Improvements in the manufacture of articles in glass, tile, pottery, metals, and like substances by a process for producing thereon letters, figures, or designs in permanent colours. Sept. 15.

21,095. J. W. Knights. Improved method of making coloured tiles for floors or building purposes. Sept. 15.

16,523. W. Cliff. Improvements in or connected with the enamelling of fire-clay baths and other articles. Sept. 1.

16,873. R. Good and R. Good, jun. Improvements in machinery for manufacturing glass vessels. Sept. 15.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

### APPLICATIONS.

20,670. T. Holden and C. Major. Improvements in the manufacture of cement. Sept. 8.

20,960. E. M. Fox. Improvements relating to the treatment of wood and other substances for rendering the same unflammable. Sept. 11.

21,141. J. A. Jones. Improvements in the manufacture of plaster for walls, ceilings, and the like. Sept. 15.

21,146. W. J. Pearce. Improvements in and connected with the vitreous decoration of walls, panels, and other surfaces. Sept. 15.

21,456. C. Heap and T. Odly. Improvements in the manufacture of cement, artificial stone, preservative composition, concrete, or the like. Sept. 18.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

18,622. G. F. Thomson. Manufacture and treatment of artificial and other stone, roofing and other tiles, and enamel and apparatus therefor. Sept. 1.

23,244. L. A. Smart and H. Robertson. Improvements in cement compositions for application in steel and iron ships and otherwise. Sept. 1.

1897.

15,083. F. D. T. Lehmann and P. N. Kohlsaat. Improvements in fireproof buildings and structures. Sept. 1.

## X.—METALLURGY, MINING, Etc.

### APPLICATIONS.

18,900. F. W. Jackson. Method of extracting gold from slimes and other deposits. Aug. 16.

19,338. J. Riley. Improvements in utilising slag or cinder from steel-melting furnaces. Aug. 21.

19,480. E. H. T. Plant and S. Dellow. Amalgamating pan. Complete Specification. Aug. 24.

19,650. Kynoch, Ltd., and A. T. Coeking. Improvements relating to blasting. Aug. 25.

19,764. A. E. Thomas. Thomas's universal converter for cleansing molten iron from its impurities and converting the same into refined iron or malleable iron or steel, as may be required to produce. Complete Specification. Aug. 27.

19,922. E. van Toll. Manufacturing vanadium and its alloys. Aug. 30.

20,312. S. O. Cowper-Coles and G. B. Pearce. Improvements in the treatment of zinc-bearing ores for the obtaining of the zinc and other metals therefrom. Sept. 3.

20,514. A. E. Tucker. Improvements in the manufacture of drawn metals. Sept. 7.

21,006. C. P. Shrewsbury and F. L. Marshall. Improvements in the treatment of pyritic ores to extract the gold and silver contained therein. Sept. 13.

21,034. W. C. Stacey.—From F. H. Keane, Roumania. Improvements in the manufacture of chilled castings. Sept. 14.

21,092. C. W. Ogden, G. Wilkins, and C. F. Morris. Improvements in and relating to the treatment of auriferous ores and deposits. Sept. 14.

21,123. T. J. Heskett and H. Jones. Improvements in the manufacture of steel. Sept. 14.

21,384. G. Attwood. Improvements in the treatment of ores. Sept. 17.

21,448. J. Baxeres and S. de la Preeilla. Improvements in or relating to the extraction of gold, silver, and other metals from ores and the like. Sept. 18.

21,483. C. Wetherwax. An improved process of treating gold ores. Sept. 18.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

14,222. A. E. Tucker and T. V. Hughes. Improvements in ferro-sodium fluxes. Sept. 1.

14,223. A. E. Tucker and T. V. Hughes. Improvements in and connected with the alloying of metals. Sept. 1.

18,537. J. Dueot. Apparatus intended to determine the quantity of metal which a galvanoplastic bath should deposit on the object treated. Aug. 25.

18,760. F. O'C. Prince. Means for introducing, diffusing, and regulating the air blast to cupolas for melting metal. Sept. 1.

20,615. A. J. Boulton.—From Kochler and Co. Improvements in or relating to the obtaining of metals or metallic compounds from ore residues or other bodies containing them. Sept. 22.

22,355. W. P. Thompson.—From A. Sinding-Larsen. Improved process for extracting metals. Sept. 1.

22,721. T. Storer. Improvements in the treatment of nickel ores for extraction of the nickel and the production of iron oxide pigment. Sept. 15.

22,923. W. Beardmore and H. V. Holden. Improvements in casting armour plates, and moulds therefor. Aug. 25.

22,976. D. C. Dalzell and A. Fairley. Improvements relating to the annealing of steel or iron. Sept. 8.

24,703. R. A. Hadfield. Improvements in the manufacture of iron alloys. Sept. 8.

25,461. W. P. Thompson. From La Société Civile d'Etudes au Syndicat de l'Acier Gerard. Improvements in the manufacture of steel. Sept. 22.

27,776. P. Marius. Improvements in or connected with the obtaining of metals or alloys by electrolysis or hydro-electro-chemical action. Sept. 8.

1897.

290. W. E. May. Improvements relating to the casting of metals and to apparatus for use in connection therewith. Aug. 25.

3932. M. Hinzelmann. An improved process for applying leaf metal. Sept. 22.

8887. O. Inray.—From The Pennsylvania Salt Manufacturing Co. Improvements in apparatus and appliances for casting metals. Sept. 8.

13,672. W. E. Harris. Method of treating and annealing sheet metal. Sept. 15.

15,569. T. G. Bowick. Improvements in and relating to the recovery of gold and other precious metals. Aug. 25.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

19,035. H. S. Jones, of the firm of W. P. Thompson and Co.—From E. Balbach, jun., United States. Improvements in electrolytic apparatus. Complete Specification. Aug. 17.

19,037. J. S. Morrison. Anodes and vats for use in the electro-deposition of nickel. Aug. 17.

19,614. T. Scott and H. Hanks. Improvements in electric storage batteries or accumulators. Aug. 27.

19,638. R. Kennedy. Improvements in electrical storage batteries and plates therefor. Aug. 25.

19,846. L. Guelzow. Manufacture of plates for electric accumulators. Complete Specification. Aug. 28.

19,959. H. Maxim. Process and apparatus for electro-thermally treating materials. Aug. 31.

20,145. A. Lehmann and A. Mann. Improvements in accumulator plates. Sept. 1.

20,428. A. E. McKeebuic. Improvements in cells for batteries and connections therefor. Sept. 6.

21,486. W. E. Heys. From The Electrical Copper Company, Ltd., France. Improvements in and connected with the electro-deposition of copper and other metals on rotary cathodes. Complete Specification. Sept. 7.

20,596. A. F. Harris. Improvements in or connected with anodes for apparatus for the electro-deposition of metals. Sept. 8.

20,703. B. E. F. Rhodin. Improved metallic diaphragm for electrolysis. Sept. 9.

20,845. A. Müller. Improvements in accumulators or secondary batteries and in means for transporting the same. Sept. 10.

21,156. F. H. Perry. Improvements in primary batteries. Sept. 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

18,570. F. Dannert. Improvements in electric batteries. Sept. 1.

21,826. T. Froggatt. Improved grids for plates in secondary electrical batteries. Sept. 22.

23,258. B. E. Preston and C. Simkins. Improvements in primary electric batteries. Aug. 25.

25,691. J. M. Moffat. Improvements in the cells or boxes of electric batteries. Sept. 22.

26,491. J. Lelestre. Improvements in and relating to electric accumulators. Sept. 1.

28,238. T. R. Canning. Improvements in anodes for the electro-deposition of nickel. Sept. 8.

1897.

1,572. H. Leitner. Improvements in electrolytes for the deposition of zinc, and for use in secondary batteries. Aug. 25.

14,598. J. Kitcher. Improvements in primary batteries or cells. Sept. 1.

16,942. C. Bertolus. An electric furnace for the application of polyphase currents in processes of fusion or decomposition by means of the voltaic arc. Aug. 25.

17,026. C. D. Abel.—From C. N. Seoneff, Russia. A new galvanic element. Sept. 1.

17,471. C. D. Abel.—From Siemens and Halske, Germany. Improvements in electric furnaces. Sept. 1.

### XII.—FATS, OILS, AND SOAP.

#### APPLICATIONS.

19,429. F. Arledter. Manufacture of resinous soap and apparatus therefor. Complete Specification. Aug. 23.

19,494. A. Cawood. Preparation or composition for scouring or washing wool, woollen textiles, or any other suitable animal or vegetable fibre. Aug. 24.

20,082. J. McKee. An improved method of and compound for treating lighting oils. Sept. 1.

20,294. W. H. White-way-Wilkinson. An improved fluorescent. Sept. 3.

20,478. W. Ambler and J. A. Gardner. Improvements in the method of and apparatus for extracting fatty matters from soap suds and like trade refuse. Sept. 7.

20,675. W. Schuh. An improved soap and process of manufacturing the same. Sept. 8.

20,840. F. J. Lothammer. An improved process for treating petroleum and its homologues. Sept. 10.

21,115. T. C. Palmer, of the firm of W. J. Fraser and Co. Improvements in the distillation of petroleum and other oil, and in apparatus therefor. Sept. 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

20,438. T. Coad. Improved means and apparatus for treating fat. Sept. 15.

23,025. F. W. Wright and The United Alkali Co., Ltd. Improvements in the manufacture and production of "dry soap" or soap-powder. Sept. 1.

26,285. E. G. Scott. Improvements in the manufacture of soap. Sept. 8.

1897.

17,738. R. Gesell. Improved process for making soap. Sept. 1.

### XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

#### APPLICATIONS.

19,030. A. H. Eyles. Apparatus for use in the manufacture of white lead. Aug. 17.

19,179. H. C. Woltereck. Process of manufacturing white lead by electrolysis. Complete Specification. Aug. 19.

19,182. F. Crane. Improvements in compounds used for the production of films, coatings, or analogous purposes. Aug. 19.

19,617. P. C. Carré. Improved material for paint and processes for manufacturing the same. Aug. 25.

19,727. R. J. Friswell and Brooke, Simpson, and Spiller, Ltd. Improvements in the obtaining of gutta percha. Aug. 26.

19,728. R. J. Friswell and Brooke, Simpson, and Spiller, Ltd. Improvements in the obtaining of gutta percha. Aug. 26.

19,729. R. J. Friswell and Brooke, Simpson, and Spiller, Ltd. Improvements in obtaining gutta percha and in the utilisation of the bye-products arising therefrom. Aug. 26.

19,736. J. E. Bedford and C. S. Bedford. Manufacture of varnish. Complete Specification. Aug. 27.

20,303. W. Ramsay. Improvements in the purification of crude commercial gutta percha. Sept. 3.

20,531. T. Thompson. A new or improved waterproofing compound or composition. Sept. 7.

20,902. W. Walters and A. Webb. Improvements in patent leather harness enamel. Complete Specification. Sept. 11.

21,328. H. Oldnall. A new or improved composition for blacking. Sept. 17.

21,398. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. Improvements in the manufacture of alizarine lamps. Sept. 17.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

22,721. T. Storer. See Class X.

1897.

8,811. R. Hingston and J. C. Rankin. An improved anti-fouling and anti-corrosive paint. Sept. 15.

17,933. W. Ramsay. Improvements in extracting and purifying gutta percha. Sept. 8.

18,519. J. Goldbleum. Improvements in or connected with the manufacture of varnishes, paints, and the like. Sept. 15.

### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

#### APPLICATIONS.

18,930. C. D. Abel.—From the firm of Vereinigte Köln-Rettweiler Pulverfabriken, Germany. Manufacture of hard, dense, horny, cellulose material. August 16.

19,216. R. Condy and A. Christen.—From J. Nussbanner, Austria. Improved process of tanning. August 19.

19,356. A. E. E. Cantley and E. Springborn. Artificial imitation leather. August 21.

19,661. H. Bolder. Improvements in liquid casein glue. Aug. 26.

19,874. E. Du Bois. Apparatus for tanning. Complete Specification. Aug. 28.

20,125. J. Mossep, jun., and E. B. Garland. An improved process for tanning hides and skins. Complete Specification. Sept. 1.

20,131. H. Sefton-Jones, of the firm of W. P. Thompson and Co. From E. Bardon, France. Improved tanning apparatus. Sept. 1.

20,273. J. Hall. Improvements in machinery for treating skins, hides, leather, and other like substances. Sept. 3.

20,354. E. J. Thibaut. Improved means to be used in the tanning of hides and skins. Complete Specification. Sept. 4.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

22,965. F. Billing and A. Letalle. A new material to be employed as a substitute for leather, paper, and other analogous substances, and a process of manufacturing the same. Sept. 1.

24,812. A. M. Clark.—From Les Fils de F. P. Heinrich. An improved tanning process. Sept. 8.

24,885. L. de Banville, J. T. Rouleau, and L. V. Rancelant. The manufacture of a substitute for leather and the like, and apparatus for use therein. Sept. 22.

1897.

15,404. A. J. Boulton.—From G. Brigant, France. Improved manufacture of artificial leather or leather substitute. Sept. 22.

16,477. J. L. Garein. Improvements in or relating to the manufacture of washable leather or skins. Aug. 25.

18,930. C. D. Abel.—From the firm of Vereinigte Köln-Rottweiler Pulverfabriken, Germany. Manufacture of hard, dense, horny, cellulose material. Sept. 22.

### XV.—AGRICULTURE AND MANURES, Etc.

#### APPLICATIONS.

19,033. H. S. Jones.—From J. Pioger, France. Improvements in the quick removal to a distance of town refuse and its conversion into manure. Aug. 17.

20,660. J. E. J. Johnson. New or improved manufacture or production of fertilising material. Sept. 8.

21,175. W. Walters. Improvements in the manufacture of artificial manures. Sept. 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

20,509. A. Schlepitzky. A new or improved artificial manure or fertiliser. Aug. 25.

1897.

17,926. W. E. Rowlands. Manufacture of manure from waste leather and phosphate of lime. Sept. 15.

### XVI.—SUGARS, STARCHES, GUMS, Etc.

#### APPLICATIONS.

19,497. E. R. Savigny. Improvements in sweetening compounds. Aug. 24.

20,152. C. J. Crossfield and S. Stein. Improvements in or connected with the manufacture of sugar. Sept. 2.

21,285. J. L. Collier. Improvements in steam pans for boiling sugar and other substances. Sept. 16.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

23,318. J. Grosse. Improvements in the granulation of crystallisable liquids and especially of the by-products of sugar manufacture. Sept. 22.

1897.

586. R. Ansoerge. An improved starch preparation and process of making the same. Sept. 22.

17,444. J. Keil. Improved process and apparatus for the production of starch and gluten out of cerealia and legumines. Sept. 15.

### XVII.—BREWING, WINES, SPIRITS, Etc.

#### APPLICATIONS.

19,161. C. O'Sullivan. Improvements in the treatment of the bye-products brewers' and distillers' yeast, or either of them, whereby a substance is obtained that can be used as a food by man, and for other purposes. Aug. 19.

19,245. A. B. Lennox. Method of and apparatus for removing impurities from alcohol and other liquids. Aug. 20.

19,759. A. Schulze. Brewing beer without the husks of the barley or malt. Aug. 27.

19,858. A. Collette, jun. Process for the extraction of alcohol by saccharification and fermentation by mucedineæ, and apparatus therefor. Complete Specification. Aug. 28.

20,103. T. Hyatt. Improvements in malt liquors and process for manufacturing the same. Sept. 1.

20,107. R. S. Kaufmann. Plant malt for ale and beer brewery purposes instead and to replace partly the barley. Sept. 1.

20,218. J. Weichmann. See Class I.

20,671. T. Skurray. Improved process for the production of fermented liquors and ferments for use in the same. Sept. 8.

20,955. J. E. J. Johnson. Improved treatment of alcoholic or fermented liquids. Sept. 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

25,852. J. Schneible. Improvements in the manufacture of fermented liquors. Sept. 22.

1897.

18,112. H. H. Lake.—From L. S. Langville and H. Tauszky, United States. Improvements in and relating to the manufacture of yeast. Sept. 22.

### XVIII.—FOODS, SANITATION, Etc., AND DISINFECTANTS.

#### APPLICATIONS.

##### A.—Foods.

19,161. C. O'Sullivan. See Class XVII.

19,215. W. Majert. Manufacture or treatment of butter for the removal of bacilli and germs. Aug. 19.

19,357. H. Higgins. Proteid breads, bisenits, and cakes. Aug. 21.

19,446. H. Grono and H. Pateson. Process of chilling and freezing meat and other alimentary substances, and means therefor. Complete Specification. Aug. 25.

19,979. C. Esteourt. Production of a valuable food for animals. Aug. 31.

19,980. C. Esteourt. Production of a new food for human consumption. Aug. 31.

20,013. E. G. N. Salenius. Method and apparatus for sterilising milk and other liquids. Complete Specification. Aug. 31.

20,527. A. W. Rothwell.—From T. T. Rothwell, Victoria. Elimination of tannin from tea in infusion. Sept. 7.

20,898. W. G. Coventry. Improvements in the application of chemical preservatives to meat. Sept. 11.

21,387. F. W. H. Graeff. Preservation of organic substances. Complete Specification. Sept. 17.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

23,785. W. Luplan. Improved apparatus for use in the aeration of milk, and for attachment to milk cans and the like receptacles. Sept. 22.

1897.

16,088. W. Horlick. Improvements in edible and soluble tablets, and method of producing the same. Sept. 15.

## APPLICATIONS.

## B.—Sanitation.

19,284. W. H. Bowers. Retorts for the drying or carbonisation of sewage matter and generally of vegetable or other substances. Aug. 20.

19,426. J. Desmaroux. Apparatus for sterilising water. Complete Specification. Aug. 23.

19,747. W. Noton. Method of and means for purifying and filtering sewage and other foul and impure water. Aug. 27.

20,832. S. Platt. Improvements in apparatus for treating sewage and other waste liquors. Sept. 10.

21,402. L. Devaux. System of purification of water. Sept. 17.

## C.—Disinfectants.

19,204. H. E. Newton.—From The Farbenfabriken vormals Friedrich Bayer and Co., Germany. See Class XX.

## COMPLETE SPECIFICATIONS ACCEPTED.

1897.

17,464. W. Loebinger. Improvements in or relating to disinfection by means of formaldehyde. Sept. 1.

18,250. H. Oppermann. Process for the preparation of easily soluble compounds of formic aldehyde for preserving, disinfecting, and therapeutic purposes. Sept. 22.

## XIX.—PAPER, PASTEBOARD, Etc.

## APPLICATION.

21,193. C. Beadle. Treatment of waste paper or the like for removal of sizing and gumming ingredients. Sept. 15.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,978. A. Masson. Improved method and means of drying and treating coated paper. Sept. 22.

22,965. F. Billing and A. Letalle. See Class XIV.

24,010. D. C. Simpson. A new or improved composition for treating paper, cardboard, wood, or other material of a similar nature, to render such material waterproof, and the markings with writing inks thereon indelible. Sept. 22.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

## APPLICATIONS.

19,014. A. J. Boulton.—From E. Vial, Belgium. Improvements in the extraction of salinate (suintine). Aug. 17.

19,204. H. E. Newton.—From The Farbenfabriken vormals Friedrich Bayer and Co., Germany. Process for producing aromatic aldehydes. Aug. 19.

19,809. E. C. C. Stanford. Improvements in pharmaceutical preparations. Aug. 28.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,031. J. G. McIntosh. Improvements in the manufacture and application of terebenthene mono hydrochloride. Sept. 22.

1897.

8387. H. Maek. Method of producing highly concentrated fat solutions of fragrant substances. Sept. 1.

9827. F. Valentiner. A process for the production of aromatic fluoro-hydrocarbons in aqueous solution. Sept. 8.

17,409. O. Inray.—From The Society of Chemical Industry in Basle, Switzerland. Manufacture of new therapeutical compounds. Sept. 8.

17,692. L. Lederer. Improvements in the process for preparing the halogen derivatives of acetone. Sept. 22.

## XXI.—PHOTOGRAPHY.

## APPLICATIONS.

18,973. E. J. Browne and F. J. Abbott, jun. Process for reproducing photographs in natural colours. Aug. 17.

19,168. C. T. Jago. Method of obtaining permanent coloured photographs. Aug. 19.

19,208. A. E. Wade. Photographic solutions as used for toning and fixing prints. Aug. 19.

29,975. H. Soar. Improved means of preparing photo mechanical surfaces analogous to collotype and the like. Sept. 13.

## COMPLETE SPECIFICATION ACCEPTED.

1896.

19,726. W. Grunow. A new or improved apparatus for developing, fixing, and toning photographs. Sept. 15.

## XXII.—EXPLOSIVES, MATCHES, ETC.

## APPLICATIONS.

18,929. C. D. Abel.—From the Firm of Gesellschaft für Lindes Eismaschinen, Germany. New explosive compound. Aug. 16.

19,259. L. Davies. Explosive cartridges. Aug. 20.

19,418. S. Neuburg and I. Neuburg. Manufacture of matches. Aug. 23.

20,099. A. E. Blondel. Improvements in fog signals. Sept. 1.

20,223. E. S. Clark. Improvements in or relating to safety tamping for explosives used for blasting operations in coal and other mines, and in apparatus for use in connection therewith. Sept. 2.

20,763. W. Hope. Improvements in sporting and other ammunition. Sept. 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

22,540. R. W. Strehlenert. A new or improved solvent or solvents for nitrocellulose whereby improved solutions are obtained. Sept. 15.

1897.

18,563. J. Caveri. Improvements in the manufacture of matches. Sept. 22.

## PATENT UNCLASSIFIABLE.

## APPLICATION.

20,775. F. J. Lothammer. Improvements in the treatment of asbestos. Sept. 9.

# THE JOURNAL OF THE Society of Chemical Industry.

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 10.—Vol. XVI.]

OCTOBER 30, 1897.

[Non-Members 30 per annum; Members  
21 per Set of extra or back numbers;  
Single Copies (Members only) 2 6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S. ....	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S. ....	1882—1883.
Walter Weldon, F.R.S. ....	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S. ....	1884—1885.
E. K. Muspratt ....	1885—1886.
David Howard ....	1886—1887.
James Dewar, M.A., LL.D., F.R.S. ....	1887—1888.
Ludwig Mond, Ph.D., F.R.S. ....	1888—1889.
Sir Lowthian Bell, Bart., F.R.S. ....	1889—1890.
E. Rider Cook ....	1890—1891.
J. Emerson Reynolds, M.D., F.R.S. ....	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S. ....	1892—1893.
E. C. C. Stanford ....	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S. ....	1894—1895.
Thomas Tyrer ....	1895—1896.
Dr. Edward Schunck, F.R.S. ....	1896—1897.

## COUNCIL FOR YEAR ENDING JULY, 1898.

President: Prof. F. Clowes, D.Sc.

### Vice-Presidents:

David Howard.	Dr. W. Jay Schieffelin.
Prof. A. K. Huntington.	Dr. Edward Schunck, F.R.S.
Ivan Levington.	G. N. Stoker.
Boverton Redwood.	Dr. T. E. Thorpe, F.R.S.
Sir H. E. Roscoe, F.R.S.	Wm. Thorp, B.Sc.
A. Gordon Salomon.	Thomas Tyrer.

### Ordinary Members of Council:

R. Forbes Carpenter.	C. C. Hutchinson.
R. Le Neve Foster.	J. S. McArthur.
Sir David Gamble, Bart., C.B.	B. E. R. Newlands.
Oscar Guttman.	John Pattinson.
Douglas Herman.	Sir Robert Pullar.
Prof. J. J. Hummel.	Walter F. Reid.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

A. H. Allen.	C. Clarke Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	J. Lewkowitsch, Ph.D.
H. Brunner.	A. R. Ling.
A. C. Claudet.	Stevenson Macadam, Ph.D.
E. Rider Cook.	Ludwig Mond, F.R.S.
Chas. Dreyfus.	B. E. R. Newlands.
Sir John Evans, K.C.B., F.R.S.	John Pattinson.
G. G. Henderson, D.Sc.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	H. R. Procter.
D. B. Hewitt, M.D.	Boverton Redwood.
David Howard.	Walter F. Reid.
Prof. J. J. Hummel.	John Spiller.
Prof. A. K. Huntington.	William Thorp.
F. Hurter, Ph.D.	Thomas Tyrer.

## NOTICES.

### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, part of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time; and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List.

	Each copy 10s.
To Subscribers, ..... „	12s. 6d.
To others, ..... „	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

Foreign and Colonial Members are reminded that the subscription of 25s. for 1898, payable on January 1st next, should be sent in good time to the Treasurer, in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th, 1898.

#### LIST OF MEMBERS ELECTED 22nd OCTOBER 1897.

- Amend, Otto P., 205-11, Third Avenue, New York City, U.S.A., Chemist.
- Andreaseh, Friedl., H. Linke Bahngasse 5, Vienna, Austria, Chemist (k. k. Lehn. Versuchsanstalt für Leder-industrie).
- Annisson, Fred. G., Hohokus P.O., Bergen Co., N.J., U.S.A., Technical Director (American Pegamoid Co.).
- Bevington, Rich. G., Village Main Reef G. M. Co., Box 737, Johannesburg, S.A.R., Metallurgist.
- Bucher, John E., Rhode Island College of Agriculture, &c., Kingston, R.I., U.S.A., Assistant Professor.
- Burls, Frank B., 20, Wellesbourne Grove, Stratford-on-Avon, Chemist.
- Challen, Matthew B., Stowell, Victoria, Australia, Assayer.
- Culmann, Dr. Julius, Farbenfabriken of Elberfeld Co., 77, William Street, New York, U.S.A., Chemist.
- Dains, Herbert H., Vizianagram Cantonment, Madras Presidency, India, Chemist.
- Davies, Chas. T., 105, Elm Street, Reading, Pa., U.S.A., Chemist.
- Dempwolf, Chas. H., York, Pa., U.S.A., Manufacturing Chemist.
- Doerflinger, Wm. F., 85, Lafayette Avenue, Brooklyn, N.Y., U.S.A., Assistant Chemist (American Pegamoid Co.).
- Dowling, Walford R., Box 158, Johannesburg, S.A.R., Chemist.
- Gossage, W. Winwood, Widnes, Lancashire, Soap Manufacturer.
- Gref, Anthony, 253, Broadway, New York City, U.S.A., Patent Lawyer.
- Hasslach, Jacob, P.O. Box 1929, New York, U.S.A., President (Roessler and Hasslach Chemical Co.).
- Heaton, John, 71, Garmyle Road, Sefton Park, Liverpool, Brewer and Chemist.
- Mallory, J. Halsey, 539A, Greene Avenue, Brooklyn, N.Y., U.S.A., Assistant Chemist (American Cotton Oil Co.).
- May, Geo. H., Hohokus P.O., Bergen Co., N.J., U.S.A., Assistant Chemist (American Pegamoid Co.).
- Nash, Leonard M., 281, Seven Sisters Road, Finsbury Park, N., Student of Chemistry.
- Peter, Dr. A. H., 205, Third Avenue, New York, U.S.A., Chemist.
- Rees, W. H., El Dorado Linseed Oil Works, West Berkeley, Cal., U.S.A., Chemist.
- Roe, Wm. Laey, Mass. Institute of Technology, Boston, Mass., U.S.A., Assistant in Oil and Gas Analysis.
- Schreiber, Fred. T., Ocala Mining Laboratory, Ocala, Florida, U.S.A., Analytical Chemist.
- Simpson, Edw. S., Geological Survey Office, 31, Pier Street, Perth, West Australia, Government Assayer.
- Vagner, Dr. Theodore B., 146, East Division Street, Chicago, Ill., U.S.A., Chemist.
- Wardle, Bernard, Leek, Staffordshire, Silk and Cotton Printer.
- Wense, Dr. Wilhelm, Westeregeln, Prov. Sachsen, Germany.

#### CHANGES OF ADDRESS.

- Bennie, J. W., 10 Greenwich; retain Journals until further notice.
- Collins, W. Hepworth, 10 Bolton; c/o O. M. Wihl, 34, Kennedy Street, Manchester.
- Colquhoun, W., 10 Garston; 18A, South Castle Street, Liverpool.
- Craven, Jno., jun., 10 Smedley Lodge; 6, Halliwell Lane, Cheetham Hill, Manchester.
- Dibdin, W. J., 10 Craven Street; Edinburgh Mansions, Howick Place, S.W.; Journals as before.
- Dupré, Dr. A., 10 Caxton Street; Edinburgh Mansions, Howick Place, S.W.
- Green, J. E., 10 Queen's Road; Grafton House, Church Road, Urmston, near Manchester.
- Halliwell, Edw., 10 Dewsbury; West Riding of Yorkshire Rivers Board, Wakefield.
- Harden, Arthur, 10 Manchester; 101, Great Russell Street, London, W.C.
- Hooper, E. Grant; Journals to 16, Royal Avenue, Sloane Square, S.W.
- Hyndman, H. H. Francis; Journals to Trinity College, Cambridge.
- Jackson, Edw., 10 Edgbaston; Clovelly, Grove Avenue, Moseley, Birmingham.
- Leather, Dr. J. Walter, 10 India; c/o Grindlay and Co., Parliament Street, London, S.W.
- Lomas, T., 10 "Cleveland"; 10, Selborne Place, Minehead, *vid* Taunton.
- Longshaw, Jas., 10 Seaforth; Hollinside, Victoria Road, Huyton, Liverpool.
- Lovejoy, F. W.; Journals to Kodak Park, Rochester, N.Y., U.S.A.
- Lynn, A. H., 10 Warrington; Garten Str. 2, Jena, Germany.
- McCrae, Dr. Jno., 10 Glasgow; Yorkshire College, Leeds, Chemical Demonstrator.
- Mercer, F. M.; Journals to 34, Camomile Street, E.C.
- Miller, Jas., 10 Glasgow; Minas do Sao Bento, Santa Barbara de Matto Dentro, Minas Geraes, Brazil.
- Morgan, J. J., 10 10; 14, Bryntyrion Street, Dowlais.
- Powter, P., 10 Johannesburg; Journals to c/o Walford Bros., 320, Strand, W.C.
- Reade, Thos.; Journals to Chemical Works, Cleveland Road, Wolverhampton.
- Riley, Jas., 10 Glasgow; Brooklands, Uddingston, N.B.
- Saeh, Robt.; Journals to c/o Jas. Owen and Co., Honda, Rep. de Colombia, South America.
- Schryver, Dr. S. B., 10 Liverpool; 27, Arundel Gardens, London, W.
- Smith, E. Ellsworth; Journals to 36, East 29th Street, New York, U.S.A.
- Tennille, G. F., 10 East Orange; c/o Southern Cotton Oil Co., Savannah, Ga., U.S.A.
- Thomas, J. W., 10 Gloucester; 2, Hampstead Hill Mansions, London, N.W.
- Thomson, G. Carruthers, 10 Glasgow; 4, The Green, Bromborough Pool, Birkenhead.
- Vaughan, J. I., 10 South Hackney; Alliston, Harold Road, Leytonstone, E.
- Vincent, Jos. A., 10 Bullitt Building; Rooms 207-8, 421, Chestnut Street, Philadelphia, Pa., U.S.A.
- Weber, C. Otto, 10 Randolph Street; Heathfield, Middleton Road, Crumpsall, Manchester.

#### CHANGE OF NAME AND ADDRESS.

- Pollak, Dr. F., 10 Princess Road; Pollock, Dr. F., 66, Lansdowne Road, Crumpsall, Manchester.

**MEMBER OMITTED FROM LIST.**

Aikman, C. M., 128, Wellington Street, Glasgow, Analytical Chemist.

**Death.**

Jackson, Thos., Beechmont, Clayton, Manchester.  
October 3rd.

**London Section.**

THE CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE, W.

*Chairman:* R. Messel.

*Vice-Chairman:* Boyerton Redwood.

*Committee:*

E. J. Bevan.	A. R. Ling.
B. Blount.	H. de Mesenthal.
W. J. Dibdin.	B. E. R. Newlands.
R. J. Friswell.	F. B. Power.
Otto Hehner.	P. Napier Sutton.
D. Howard.	Wm. Thorp.
J. B. Knight.	T. Tyrer.

*Hon. Local Secretary:*

John Heron, 110, Fenchurch Street, E.C.

**SESSION 1897-98.**

Nov. 1st:—

W. Harry Stanger and Bertram Blount. "The Adulteration of Portland Cement."

Dr. W. P. Evans. "An Improved Adjustable Drip-Proof Burette."  
Dec. 6th.—H. L. Sulman and Dr. F. L. Teal. "The Sulman-Teal Process of Gold Extraction."

**Liverpool Section.**

UNIVERSITY COLLEGE, BROWNLOW STREET.

*Chairman:* Charles A. Kohn.

*Vice Chairman:* G. Schack-Sommer.

*Committee:*

P. Bateson.	W. Norris Jones.
J. Campbell Brown.	A. Smetham.
Eustace Carey.	T. W. Stuart.
M. Lloyd Davies.	Frank Tate.
W. D. Herman.	A. Watt.
F. Hurter.	

*Hon. Treasurer:* W. P. Thompson.

*Hon. Local Secretary:*

T. Lewis Bailey, University College, Liverpool.

**SESSION 1897-98.**

Oct. 27th.—Chairman's Address. "The Manufacture and Properties of Carborandum."

**Manchester Section.**

ROOMS OF THE CHEMICAL CLUB, VICTORIA HOTEL.

*Chairman:* George E. Davis.

*Vice-Chairman:* Peter Hart.

*Committee:*

F. H. Bowman.	J. Lewkowitsch.
R. Forbes Carpenter.	A. Liebmann.
B. W. Gerland.	A. Ree.
J. Grossmann.	E. Schunck.
J. M. Irving.	C. Truby.
E. Knecht.	D. Watson.
I. Levinstein.	

*Hon. Local Secretary:*

J. Carter Bell.

Bank House, The Cliff, Higher Broughton, Manchester.

**SESSION 1897-98.**

Nov. 5th.—Chairman's Address. "Recent Developments in the Chlorine Industry."

**Newcastle Section.**

*Chairman:* F. S. Newall.

*Vice-Chairman:* G. T. France.

*Committee:*

A. Allhusen.	John Morrison.
P. P. Bedson.	John Pattinson.
T. W. Hogg.	W. W. Procter.
H. Louis.	W. L. Rennoldson.
T. W. Lovibond.	G. Sisson.
N. H. Martin.	J. E. Stead.

*Hon. Local Secretary and Treasurer:*

Saville Shaw, Durham College of Science, Newcastle-on-Tyne.

**Nottingham Section.**

UNIVERSITY COLLEGE, NOTTINGHAM.

*Chairman:* J. O'Sullivan.

*Vice-Chairman:* J. M. C. Paton.

*Committee:*

L. Archbutt.	W. G. Johnston.
S. F. Burford.	J. F. Kempson.
F. J. R. Carulla.	F. E. Lott.
R. M. Caven.	J. J. Sudborough.
F. Clowes.	G. J. Ward.
H. Forth.	

*Treasurer:* S. J. Pentecost.

*Hon. Local Secretary:*

J. T. Wood, 29, Musters Road, West Bridgford, Nottingham.

**SESSION 1897-98.**

Oct. 27th.—F. J. R. Carulla. "Nitrate of Soda in Iron Metallurgy."

**Dorkshire Section.**

*Chairman:* Thos. Pairley.

*Vice-Chairman:* Christopher Rawson.

*Committee:*

H. E. Aykroyd.	J. J. Hummel.
F. W. Branson.	W. McD. Mackey.
J. Cohen.	H. R. Procter.
N. Farrant.	F. W. Richardson.
T. Glendinning.	A. Smithells.
A. Hess.	Geo. Ward.

*Hon. Local Secretary and Treasurer:*

H. R. Procter (*pro tem.*), The Yorkshire College, Leeds.

**Scottish Section.**

*Chairman:* G. T. Beilby.

*Vice-Chairman:* G. G. Henderson.

*Committee:*

A. C. J. Charlier.	R. C. Menzies.
John Clark.	E. Ostlere.
R. Cox.	Sir R. Pullar.
C. A. Fawcitt.	J. B. Readman.
J. Gray.	H. Rose.
D. Harris.	P. Rottenburg.
R. A. Inglis.	E. C. C. Stanford.
Robt. Irvine.	D. R. Stewart.
W. J. Macadam.	R. T. Thomson.
A. Macdonald.	

*Hon. Secretary and Treasurer:*

Thomas Gray, Technical College, 204, George Street, Glasgow.

**SESSION 1897-98.**

A special meeting for the Oil Industry will be held at Broxburn on Monday, Nov. 29th, subject:—"Recent Improvements in Retorting."

Any members who desire to contribute to the proceedings of this meeting should at once communicate with the Hon. Local Secretary as above, from whom all particulars may be obtained.

## New York Section.

Chairman: Charles F. Chaudler.

Vice-Chairman: T. J. Parker.

### Committee:

H. Clementson.  
Virgil Coblenz.  
H. Endemann.  
W. F. Fuerst.  
Jas. Hartford.  
W. D. Horne.  
E. J. Lederle.

G. A. Prochazka.  
Clifford Richardson.  
Wm. Jay Schueffelin.  
R. C. Schupphaus.  
G. W. Thompson.  
Max. Toch.

Hon. Treasurer: R. C. Woodcock.

Hon. Local Secretary:

Dr. H. Schweitzer, 77, William Street, New York, U.S.A.

### SESSION 1897-98.

The Session was opened on October 22nd by an address from the Chairman. Five papers were also read.

Meetings will be held on the third Friday after the first Monday in every month. The meeting on Nov. 19th will be held at Columbia College, on Washington Heights.

## Obituary.

### VICTOR MEYER.

GEHEIMRATH AND PROFESSOR OF CHEMISTRY IN  
HEIDELBERG UNIVERSITY.

CHEMICAL science has lost one of her most distinguished men, and Germany one of her most enthusiastic teachers, by the sudden death of Victor Meyer. In that loss it may with truth be said that all the civilised world participates, for students came from far and near to enjoy the advantages of his direction of their studies in the laboratory, and of listening to his masterly expositions in the lecture room.

Victor Meyer was born on Sept. 8, 1848, in Berlin. He was the son of Jacques Meyer, a cotton manufacturer of that city, well known for his large-hearted benevolence. As a youth of 16 years of age he had passed through the Werder Gymnasium, and been entered as a student of Berlin University. After one semester's study here, he went to Heidelberg to study under Bunsen, and later on, having obtained his degree of Doctor of Philosophy with the highest distinction, he became Bunsen's assistant. After considerable promotion in Heidelberg, he went to continue his studies under A. von Baeyer in Berlin, and from thence he went, in 1871, to Stuttgart Polytechnicum to be the first assistant of Fehling, and also as Professor of Organic and Theoretical Chemistry. A year later he obtained the post of Professor of Chemistry in the Polytechnicum of Zurich in place of Wislicenus, and this post he filled with brilliant success for the space of 12 years. In 1885, he went to Göttingen, and in 1889 to Heidelberg as successor to Bunsen. Bunsen had proposed him as "the most gifted of my pupils." In 1890, it became necessary to commence the work of erecting new laboratories, and in 1892 the new building was completed, and very soon afterwards it was found that the accommodation still failed to suffice for the increased and ever-increasing influx of students. In the last year or so, on the average, 50 to 60 applications for places in the laboratory per semester, had to be refused for sheer lack of space.

The reason for this is easily given. Victor Meyer worked not in one department of his science, but in all departments, and in each he had won distinction. We owe to him the discovery of the aliphatic nitro-compounds. He enriched the branch of chemical physics with numerous improved methods and instruments. The older methods of vapour-density determination, so troublesome in detail, he materially simplified, and introduced his now well-known method by displacement of air, for the determination of the vapour densities of substances boiling or vaporising at exceedingly high temperatures.

Victor Meyer was the discoverer of the aldoximes and ketoximes—two new classes of substances important for the characterising of the aldehydes and ketones. But his discovery of greatest importance to technologists was that of Thiophen and its homologues. At the time great surprise was caused by the fact that a substance so much investigated as the so-called "pure benzol" should still be found to contain an extraneous body—a sulphur compound, too. Having isolated this substance in a state of purity, Victor Meyer and his pupils worked upon it and its derivatives, and at length published a book devoted to their researches thereon, and entitled "Die Thiophengruppe" (Vieweg, Brunswick, 1888).

Victor Meyer was, in 1882, elected a corresponding member of the Bavarian Academy of Sciences, and in 1883 a foreign member of the Chemical Society of London.—W. S.

## I.—PLANT, APPARATUS, AND MACHINERY.

*Heating Fluids and Distilling [Water, &c.], Impts. in or relating to.* A. J. Boulton, 111, Hatton Garden, London.

From A. G. Waterhouse, Hartford, Connecticut, U.S.A.  
Eng. Pat. 16,035, July 6, 1897.

THE invention, when applied to the process of distilling liquids, consists of a method of and means for transferring the heat given off by the condensation of the steam or vapours, and by the condensate, to the liquid to be distilled while on its way to the still. When used merely for the purpose of heating liquids, the heat is transferred from the liquid passing from the heating apparatus to that passing to the same. The figure illustrates one typical form of the apparatus employed, several modifications, including "multiple-effect" arrangements, being also described in the specification. The liquid is fed through the pipe A<sup>1</sup>, coil A<sup>2</sup> (which encloses the return coil A<sup>3</sup>), pipes A<sup>4</sup>, heating tank S, and pipes A<sup>5</sup>, A<sup>6</sup> to the still B, the condensed steam or vapours from the still being returned through the chamber C, pipes A<sup>7</sup>, A<sup>8</sup>, coil A<sup>9</sup>, and pipe A<sup>10</sup>.

\* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to C. N. Dalton, Esq., Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

authors with liquefied acetylene, the bottle was smashed to small fragments.

**III. *Liquefaction of Dissolved Acetylene (and of the Vaporizer) to Inflammation.***—A 50 c.c. steel tube, provided with crusher manometers, was charged with 14 c.c. of acetone in a first set of experiments and 8.2 c.c. in a second set. The acetone was saturated with acetylene at the ordinary temperature, and at pressures varying from 10 to 20 kilos. per sq. cm. When the initial pressure did not exceed 10 kilos., and the inflammation was produced by an incandescence platinum wire in the gas, the observed pressures did not differ from those corresponding to the combustion of pure acetylene under the same pressure. From this it may be concluded that the dissolved acetylene is not decomposed, and that it takes no part in the combustion. The maximum pressures observed are only one-tenth of those which would correspond to the explosive decomposition of the whole of the contained acetylene (gaseous and dissolved). But when the initial pressure exceeds 10 kilos., the effect produced becomes analogous to the explosion of pure liquid acetylene. Not only is the acetylene decomposed; the acetone which holds it in solution is also destroyed simultaneously. The explosive decomposition produces a compact mass of carbon, which takes the form of the tube. The gases formed consist of hydrogen and carbon monoxide, mixed with carbonic acid. The experiments have been repeated with a larger receiver (13.5 litres) of the kind commercially used. It is found that the bottles ordinarily used (tested to 250 atmospheres) can support without rupture the pressure resulting from an accidental inflammation of the gaseous atmosphere contained in the bottles (the acetone having been saturated with acetylene at pressures of 6 to 8 kilos. and temperatures of 10°–15° C.). The pressure developed does not exceed 155 kilos. But these bottles are no longer safe if the initial pressure exceeds 10 kilos., or if they are exposed to temperatures exceeding 35° C. With an initial pressure of 20 kilos., when the inflammation is produced in the gaseous atmosphere, it can develop a pressure of 568 kilos., and when it is produced in the liquid itself, the pressure rises to 5,100 kilos. No commercial receiver is safe under such conditions.

Finally, acetylene is less dangerous when dissolved in acetone, for it cannot be exploded by internal inflammation when the pressure is below 10 kilos. and the temperature below 15° C. Acetylene *per se* can be exploded by internal inflammation when a receiver of a litre capacity contains 2.5 grms. or more of it. Under the conditions stated the same receiver could contain without risk nearly 50 times as much acetylene (100–120 grms.) dissolved in acetone.

—D. E. J.

***Solutions of Acetylene, Remarks on their Explosive Decomposition.*** Berthelot and Vieille. *Comptes Rend.* 1897, 124, [19], 996–1000.

WHEN acetylene is heated in contact with its solution in acetone (in a closed receiver), under certain conditions the dissolved acetylene suffers no decomposition, whilst under other conditions it suffers explosive decomposition. In the latter case the solvent (acetone) is decomposed, and in the main decomposed into its elements, carbon and hydrogen; the oxygen appears in the form of carbon monoxide and dioxide and water—

This total decomposition of the solvent is produced by the explosive shock resulting from the destruction of the acetylene at constant volume. It is exceptionally interesting as an example of the sudden and total destruction of a substance which is formed (as acetone is) with evolution of heat. The determining factor in the conditions, is the pressure. The authors proceed to explain, from thermochemical considerations, why acetylene dissolved in acetone is stable up to a certain pressure (about 10 kilos. per sq. cm.). The decomposition of 26 grms. of gaseous acetylene into its elements, evolves + 51.4 calories; allowing for the heat of solution of dissolved acetone, this would be reduced to + 46.3 calories. The heat of

vaporisation of a molecule of acetone is 7.5 cal., so that the decomposition of a molecule of acetylene would suffice to vaporise 6 mols. (or 13 times its weight) of acetone. Such would be the effect produced in a solution containing 77 grms. of acetylene per kilo. of acetone. To this must be added the heat required to heat to the same temperature the carbon and hydrogen produced by the decomposition of the acetylene. Clearly, the high temperature required for the total destruction of the acetylene cannot be attained under these conditions: a much larger percentage of the endothermic compound is required. At a pressure of 10 kilos. per sq. cm., 1 kilo. of acetone dissolves 350 grms. of acetylene: the latter by its own decomposition would evolve 623.3 cal. This, at constant volume, would raise the mixture of acetone (supposed unaltered), carbon, and hydrogen to 730° at most. Now, this temperature is not high enough to decompose acetylene into its elements. A similar calculation for acetone saturated with acetylene under a pressure of 20 kilos. (and containing 700 grms. of acetylene per kilo. of acetone) gives a temperature of 1,300°, which is about the actual temperature of decomposition of acetylene. The above calculations are only approximate, and reference must be made to the original for further developments; e.g., the heat absorbed in the decomposition of the acetone into carbon, hydrogen, and carbonic acid would reduce the above temperature to 1,160° C. But this same decomposition would determine an increase of volume from 1 to 3½; or, at constant volume, a corresponding increase of pressure. Taking both into account, the decomposition of the acetone would result in a doubling of the final pressure, as compared with that due to the decomposition of the acetylene alone. Under high initial pressures the acetone may become a source of danger rather than of safety.—D. E. J.

***Acetylene, Conditions of the Propagation of the Decomposition of.*** Berthelot and Vieille. *Comptes Rend.* 1897, 124, [19], 1000.

THE authors have already shown that, under the normal pressure, a decomposition excited at any point in an atmosphere of pure acetylene gas does not spread throughout the mass; but that at higher pressures (about double the normal) the gas exhibits the properties of an explosive mixture. At a given pressure the tendency to propagation is affected by other conditions (mode of excitation and external cooling effects). They have now studied the intermediate state and conditions (under which an explosion sometimes occurs, at other times not) using various methods of exciting decomposition, both in large receivers (4 to 25 litres) and in metallic tubes 3 m. long and 22 mm. in diameter. The results (details of which are given) show that for a given mode of excitation it is not possible to specify an absolutely fixed critical pressure, such that below it propagation would be impossible, whereas above it propagation would be certain. The change takes place gradually, following a scale of pressures to which correspond increasing probabilities of explosion. This behaviour is not peculiar to acetylene. For all explosive substances the phenomena of propagation present the same character. The conditions of certain explosion are always separated by a large interval, from those of assured safety. Between these there exist zones of danger, and it is impossible to define anything beyond the probability of an explosion occurring.—D. E. J.

***Acetylene: Solution in Acetone.*** C. H. Bothamley. Photography, Sept. 1897. (See this Journal, 1896, 793; 1897, 318, 319, and 524, and the foregoing three abstracts.)

THE practical points that the author deduces from the foregoing researches of Berthelot and Vieille, are summed up in the following conclusions for those who use acetylene generators:—(1) Avoid the use of copper or brass in the construction of the apparatus, whether for generating or storing, and (2) take care that the pressure in the apparatus as a whole, or in any part of it, never exceeds half an atmosphere above the ordinary atmospheric pressure. If these points are strictly attended to, the danger of any explosion of the acetylene is very small, provided, of course, that it does not become mixed with air.

*Incandescent Gas Light, The Theory of.* C. Hohnmann. J. für Gasbeleucht. 1897, 40, 156.

**KILLING** (this Journal, 1896, 794) has advanced the theory that mantles composed of thoria with a small proportion of ceria, platinum, &c., owe their light-emissive power to the ceria, &c., acting catalytically as oxygen-carriers, which present oxygen to the gas flame in the nascent state, thus producing a higher temperature in the region of the mantle. Geelmuyden found that ordinary slit- and Argand burners gave no imperfectly burnt gaseous products, whereas Welsbach burners frequently yielded small quantities of these; and Krebs has utilised these results in attacking Killing's theory, which he considers to imply that a more perfect combustion should take place in a Welsbach burner than in an ordinary gas flame.

The author points out that with burners having badly arranged air-inlets, imperfectly burnt gas may readily escape, but that Bunte has found that the gaseous products from Welsbach burners, acting under normal conditions, only contain mere traces of carbon monoxide; this he also found was the case with an ordinary slit-burner. Krebs' experimental data are thus controverted. But it does not follow that the emission of incompletely burnt gas would be evidence against Killing's theory. The oxygen-carrying action of the ceria does not necessarily lead to a more complete combustion, but merely to an increased velocity of reaction at the point of contact. It might even be that the greatly increased temperature would be a condition unfavourable to the complete combustion of the rest of the gas.—H. B.

*Acetylene, Method of Estimating, Applicable to Acetylides of the Formula  $R.C \equiv C.H$ .* Chavastelon. Comptes Rend. 125, [4], 215.

See under XXIII., page 828.

#### PATENTS.

*Peat, A Process for Carbonisation of, by Electric Heating.* P. Jøbsen, Brvik, Norway. Eng. Pat. 22,194, Oct. 6, 1896. (Date claimed under Internat. Conv., March 13, 1896.)

PEAT is carbonised in retorts lined with asbestos, &c., against which are coiled iron wires for carrying the current. Other iron wires may be coiled around an insulating covering fixed on a central hollow stem. The drawings attached to the specification show three retorts carried upon central bearings, so that the peat and charcoal may be charged into and discharged from the retorts through the same lid, the retort being turned, with the end covered by the lid, upwards or downwards as required.—R. S.

*Peat and its Products, Impts. in or relating to the Treatment or Utilisation of.* W. W. Hughes, Queen Victoria Street, and S. Wilson, Wembley, Middlesex. Eng. Pat. 20,084, Sept. 10, 1896.

CALCIUM carbide is prepared from peat by carbonising the latter in a vertical retort, in which it is supported upon inclined partitions, which may be slid out so as to allow it to pass gradually downwards to the bottom and hottest part of the furnace. The carbonised peat is then pulverised, mixed with finely divided lime, and then preliminarily heated, and afterwards intensely heated in an electric furnace to form the carbide.—R. S.

*Charring Peat, Wood, or the like; Impts. relating to the Method of, and to Apparatus therefor.* S. G. Lauenius, New York. Eng. Pat. 11,851, May 12, 1897.

THE method consists of discharging the heavier gases formed during the carbonisation, from the lower part of the retort, and of introducing steam or water into the retort when the charring should be stopped or the temperature reduced. The former is effected by one or more openings covered by a hood, in the bottom of the retort, through which the gases enter a small chamber, provided above with two valves—a lighter one leading to an outlet pipe having a valve, and a heavier one, through which the products pass when the valve on the first is closed, leading to the furnace, where they are consumed.—R. S.

*Smokeless Inflammable Wick, Process for Manufacturing.* A. H. Freise, Hamme-Bothum, Prussia. Eng. Pat. 12,021, May 14, 1897.

THE wick is formed of a loose coarse felt or similar material, or of paper or paper pulp, and is covered with three coatings, namely: (1) of inflammable paste, (2) of powdered sulphur with the addition of a compound of oxygen, (3) of powdered sulphur mixed with stearine, paraffin, or the like. The layers are fixed to the wick with suitable adhesive substances, as glue, gum, albumin, or resins, or by adding to the pulpy material when such is used to form the wick, or (when the coating contains sulphur) by means of hot rollers.—R. S.

*Liquid Fuel Burners, Impts. in.* La Société des Générateurs à Vaporisation Instantanée. Système. L. Serpollet and L. Serpollet, Paris. Eng. Pat. 12,438, May 19, 1897.

PETROLEUM or other liquid hydrocarbon is forced, in larger or smaller quantities, by pressure from a compressed air reservoir, into a burner having a central body serving as a boiler, wherein the hydrocarbon is vaporised, and from which it passes as vapour to a set of nozzles directed upwards, downwards, or horizontally, and arranged in the axes of Bunsen passages, into which the jet draws the surrounding air. The air and vapour, heated by contact with and radiation from the walls, are ignited, and the jets impinge against plates of refractory material, which deflect them. The preliminary heating of the petroleum for starting the apparatus may be effected in various ways.—R. S.

*Electrical Furnaces, Impts. in.* [Wedge-shaped Electrodes.] C. D. Abel, London. From Siemens and Halske, Berlin, Germany. Eng. Pat. 17,471, July 24, 1897.

TO ENSURE an automatic downward feed of the material to be treated, the upper electrode in this electric furnace is wedge-shaped or conical while the lower is hollow or funnel-shaped. The cylindrical portion of the upper electrode is surrounded with a casing and provided with flanges, which the regulating motion of the arc causes to loosen the material, and counteracts the tendency to cake, while the gas generated, escapes through the interspace between the casing and the electrode. The pulverulent material to be treated is formed into lumps or briquettes with some suitable binding substance so as to facilitate the escape of the gases, and provision is made for withdrawing the product during working, by means of a hole in the bottom of the funnel, below which, at a suitable distance, is placed a laterally extending closing-piece, or by a tapping device consisting of a lateral opening in the lower part of the funnel, opposite which is placed a boring tool for periodically making a hole in the crust formed, and withdrawing the fluid material.—G. H. R.

*Illuminating Gas, Impts. in the Manufacture of.* W. Young, Peebles; S. Glover, St. Helen's; and T. Glover, West Bromwich. Eng. Pat. 20,125, Sept. 11, 1896.

TO remove or prevent the deposition in the solid form of the naphthalene present in large quantity in gas resulting from the carbonisation of coal at high temperatures, the inventors propose to wash the gas with liquid hydrocarbons capable of dissolving out the naphthalene, and having at the same time a sufficiently high vapour-tension to prevent the absorption of the illuminating constituents. The illuminating power of the gas may be increased by carburetting with the products obtained by carbonising or cracking canal coal, shale, blast-furnace petroleum, paraffin oils, &c. at low temperatures, in such a manner that the said products are nearly free from naphthalene, and are consequently able to dissolve this substance, whilst they contain volatile hydrocarbons, which they yield up to the gas under treatment.

THE operation of carburetting is performed after the gas has been cooled and freed from tarry matters and naphthalene as far as possible, by condensation; and the naphthalene is separated from solution by cooling, the solvents being afterwards used over again—after cracking, once more if they contain a sufficiency of paraffins and olefines to yield a further supply of volatile hydrocarbons.

Another method proposed is the use of the vapours of hydrocarbons capable of dissolving naphthalene, and having the same vapour-tension as the latter, so that if the naphthalene be deposited, as a result of cooling, the said hydrocarbons will be simultaneously liquefied, and carry it into solution.—C. S.

*Inventors of Lamps, Impts. in Hydrocarbon.* R. Haddon, London. From J. W. Allison, New York. Eng. Pat. 3447, Feb. 9, 1897.

THE oil is fed to a vertical vaporising tube, situated close to the burner or burners, and conveying the vapours into an upper vertical tube leading to the mixing chamber, air being drawn in at the point of junction between the two tubes, through a transverse tube mounted in a bell-shaped hood below the mixing chamber, against which it directs the hot air and gases from the burners. From the mixing chamber, pipes convey the vapour and air down to the burners. The vaporising tube is surmounted by a cap forming a needle valve, the needle of which is enclosed, for protection, in a small tube, and passes down through a stuffing box at the lower extremity of the vaporising tube. The valve is closed and opened by moving a slotted sleeve engaging with a lug on the stuffing box, and thus regulates the supply of oil vapour to the mixing chamber.

To start the lamp, a cup situated on the base of the burner and surrounding the vaporising tube, is filled with oil or alcohol, which, when lighted, heats the said tube and generates sufficient vapour to supply the burners at the outset, the heat from the latter afterwards sufficing to maintain the supply.—C. S.

*Calcium Carbide and the like, Impts. in the Manufacture of, and in the Method of using the same in Lamps or Generators.* F. H. Smith, Danblau, N.B. Eng. Pat. 13,103, May 27, 1897.

THE calcium carbide or other compound is powdered and compressed to form tablets, or is mixed with oil or the like to the consistency of dough, and is then formed into pills, tablets, &c. The tablets, &c. are coated with wax, varnish, or other waterproof substance. In use, they are mechanically fed from an upright tube, and means are provided for abrading the varnish at one place on each tablet, so as to allow the water to act thereon.—R. S.

*Gas Generators (Acetylene), Impts. in.* C. H. Campbell, Philadelphia, U.S.A. Eng. Pat. 12,120, May 15, 1897.

THE supply of calcium carbide to the generator is automatically regulated by the movement of the gasometer, by means of a rack mounted on the latter and actuating a pinion which, by intermediate sprocket gearing, works a spiral conveyor in the bottom of the carbide chamber. This motion is produced only during the descent of the gasometer cover, a ratchet and pawl on one of the sprocket wheels preventing a reversed movement during the ascent of the cover. A valve in the neck of the generator is so attached, by a lever and swinging yoke, to the cover of the carbide chamber, that when the latter is opened, the valve closes and prevents the escape of gas.—C. S.

*Acetylene Gas, Impts. in Apparatus for Generating and Storing.* E. Chesnay and L. Pillon, both of Dijon, France. Eng. Pat. 20,091, Sept. 10, 1896. (Under Internat. Convention.)

IMPROVEMENTS in the apparatus claimed under Eng. Pat. 18,992 of 1896 (this Journal, 1897, 665) are described. They comprise a composite support for the carbide, a cylindrical bell over the container, and a layer of oil above the water in the generator.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for Generating and Storing.* E. Chesnay and L. Pillon, both of Dijon, France. Eng. Pat. 20,254, Sept. 12, 1896. (Under Internat. Convention.)

THIS is supplementary to Eng. Pats. 18,992 and 20,090 of 1896 (see foregoing). The supply of water to the carbide is controlled by the displacement caused by a float attached to the gas-holder, or by an oscillatory movement of the apparatus.—J. A. B.

*Acetylene Gas Generators and Gasometers, Impts. in.* E. H. Maddock and W. Jones, both of Liverpool. Eng. Pat. 22,359, Oct. 8, 1896.

AN inverted vessel has an annular space divided into compartments, each of which contains a generator, from which the gas passes into the central space of the vessel. Conical caps seal the tops of the generators or the vacant compartments. Water condensed from the gas is removed by a drip-tap at the lower end of an inclined exit pipe.

—J. A. B.

*Acetylene Gas, Impts. in and connected with the Production of.* I. F. FitzGibbon, London. Eng. Pat. 22,526, Oct. 10, 1896.

A sheet-metal vessel, containing water, has either a side shoot below the water-level for the admission of carbide, or a vertical feed-tube closed by a conical float. Ammonia is removed from the gas by the use of dilute hydrochloric acid either as the decomposing liquid or in a washer. The decomposition is moderated by agglutination of the carbide with 8 to 10 per cent. of paraffin.—J. A. B.

*Acetylene Gas, Impts. in or relating to Apparatus for the Manufacture of.* C. F. J. B. Bécherel, Paris. Eng. Pat. 23,289, Oct. 20, 1896. (Under Internat. Convention.)

A GASHOLDER acts as or actuates a float which, by displacement of water within a reservoir, causes an overflow therefrom to an acetylene generator, which discharges into the gasholder.—J. A. B.

*Acetylene Gas, Impts. in or relating to Apparatus for the Manufacture of.* C. F. J. B. Bécherel, Paris. Eng. Pat. 23,290, Oct. 20, 1896.

IS supplementary to the preceding specification. Two or more generators, arranged stepwise, or in other manner, are put in operation in turn by the float or floats actuated by the gasholder.—J. A. B.

*Acetylene Gas Generator, An Improved Automatic.* A. J. Smith and A. G. Smith, both of Aberdeen. Eng. Pat. 24,414, Nov. 2, 1896.

A FIXED gasholder, open at the bottom to its containing tank, communicates by a U-tube with the side of a carbide chamber provided with a gas-exit to the gasholder. Water passes to the chamber until the gas in the holder depresses its level below the mouth of the U-tube. By means of two U-tubes and a four-way cock, two carbide chambers may be used in turn. Partitions to prevent splashing on board ship are inserted in the holders.—J. A. B.

*Acetylene, Impts. in Apparatus for the Manufacture of.* P. de Resener and H. L. A. Luchaire, both of Paris. Eng. Pat. 24,410, Nov. 2, 1896. (Under Internat. Convention.)

TWO closed receivers for carbide of calcium are connected with the bottom of the tank of a bell gasholder; and also, by inverted U-tubes passing over its rim, with a point a little above its bottom. A pipe, entering the top of the bend of each of these tubes, communicates with the interior of the bell, and permits the flow of water to the receivers only when the bell is low. The receivers are used alternately. Superposed boxes for carbide, and translucent receivers are claimed.—J. A. B.

*Acetylene Gas, An Improved Apparatus for the Manufacture of.* U. Kesselring, St. Imier, Switzerland. Eng. Pat. 9714, April 15, 1897.

A DISTRIBUTING drum, divided into sectors, is charged with calcium carbide. A valve, operated by means of levers by the rise and fall of a gasholder bell, discharges the contents of each sector in succession into a water-box, whence the gas formed passes through a purifier containing moss to the gasholder.—J. A. B.

*Carbide of Calcium, An Improved Furnace for the Production of.* R. Haddon, London. From H. Colberg, Adrien Serret, and F. Amigo, Ibero. Eng. Pat. 16,398, July 10, 1897.

ACETYLENE gas, alone or mixed with a supporter of combustion, is injected into the fuel-burning chamber of a

furnace for the preparation of calcium carbide, in order to add to the temperature produced by the ordinary combustible in the furnace.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for the Generation of.* G. C. Marks, London. From A. P. Bowers, Paris. Eng. Pat. 16,975, July 17, 1897.

Water is supplied to acetylene generators by the regulating device claimed in Eng. Pat. 13,511 of 1896 (this Journal, 1897, 721). The gas, water, and lime pass together from the generators to a separator, where the lime is retained, the water discharged, and the gas allowed to pass to the burners. A modification, which is also described separately as applied to a household lamp, has a distinct gas outlet to the place of consumption, with a side arm in communication with the device which regulates the supply of water to the generator.—J. A. B.

*Acetylene Gas Generators, Impts. in.* E. Godin, Three-Rivers, Quebec, Canada. Eng. Pat. 17,021, July 19, 1897.

A BELL-SHAPED vessel supported in a tank of water communicates by two pipes—one below, one above the level of the water in the tank—with a vessel containing carbide. Water flows through the lower pipe on to the latter until the gas generated passing through the upper pipe depresses the water level within the bell. The gas exit is from an arm of the upper pipe.—J. A. B.

*Oil Vapour Burners, Impts. in.* G. C. Marks, London. From J. Gilbert, Paris. Eng. Pat. 23,801, Oct. 26, 1896.

THE oil to be vaporised, for the production of a non-luminous flame for heating an incandescent mantle, is fed to the vaporising chamber through one or more tubes filled with thin metal wires regulating the delivery by capillary attraction. The gas passes down from the said chamber through tubes leading to the nozzle of the burner, where it becomes mixed with air, and burns, the flame heating the vaporising chamber and the superimposed mantle. The initial heating of the vaporising chamber is effected by any suitable means, such as the flame of a spirit lamp, but when once started the flame is self-maintaining.—C. S.

*Benzine Lamp, Improved.* L. d'Haemars, Brussels. Eng. Pat. 21,659, Sept. 30, 1896.

THE benzine receiver is surmounted by an annular receiver containing alcohol and fitted at one side with a small

burner and wick. The burner of the main lamp rests on the alcohol lamp, through the central tube of which a tube from the main burner passes down into the benzine receiver. The wick contained in this tube allows the benzine to ascend into a blind lateral duct, or retort, at the top, directly over the alcohol flame, whereby the benzine is vaporised, and the resulting gas ascends, mixed with air, into the main burner, where it is ignited, and burns. It is claimed that in this manner a perfectly regular flame is produced with a very small consumption of alcohol.—C. S.

*Night-Lights, Impts. in.* J. D. and H. Palmer and H. E. Trestrail, London. Eng. Pat. 21,374, Sept. 26, 1896.

FOR the more effectual diffusion of disinfectants and perfumes by the heat of burning night-lights, the former, instead of being mixed with the fat, are disposed in compartments so placed as to be heated by the flame. Thus the more volatile substances are placed in an outer jacket attached to the night-light or forming part of the glass vessel in which it is placed. Less volatile matters are contained in tubes of small bore inserted into holes in the fat near to the wick. Or, the volatile substance may be absorbed by blotting paper, which is wrapped round the fat and protected by a coating of wax outside.—L. A.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Mineral Oils, Solubility in Absolute Alcohol.* S. Aisigmann. Chem. Rev. Fett-u. Harz-Ind. 4, [12], 161—163; [13], 176—180.

CONTINUING his researches (see this Journal, 1895, 812) for a simple method of determining the local origin of mineral oils from their behaviour in presence of this solvent, the author finds that the crude oils are unsuitable for this purpose, as are also the fractions boiling below 250° C., the latter being readily miscible in absolute alcohol. He therefore proposes the distillation (by the Engler fractional method) of 100 c.c. of crude oil and the collection of the fraction coming over between 250° and 270° C., 5 c.c. of which are then well shaken up with successive additions of alcohol (sp. gr. 0.705) until the initial turbidity gives place to a clear solution. The following results were obtained for the oils indicated:—

The author considers that the relative solubility of the fractions affords support to the views of Engler and Jeziaran-sky (this Journal, 1896, 191) on the nature of the hydrocarbons predominating in the fractions below and above 200° C., the former being saturated hydrocarbons miscible with alcohol in all proportions, and the latter (above 250° C.) more or less readily soluble according as they belong to the aliphatic or naphthene series.—C. S.

#### Petroleum Trade, Russian. Eng. and Mining J. 64, [4], 95—96.

THE United States Consul at Batoum reports that the increasing depth to which wells in the Baku district have to be sunk has considerably heightened their cost. At Balakhani, paying oil is still met with at between 500 and 700 ft., but at Sabountchi the oil layer is about 1,100 to 1,400 ft., and at Romani and Bibi-Eibat the latter depth is exceeded. The average cost of wells at Baku—based on a surface diameter of 26 ins., lined with 175-ft. of 26-in. pipe ( $\frac{7}{16}$  to 1-in. iron), 313 ft. of 24-in., 455 ft. of 22-in., 735 ft. of 20-in., and 1,025 ft. of 18-in. pipe, the well being finished with 1,148 ft. of 16-in. pipe—is about 1,000l.

Two large flowing wells were struck at Bibi-Eibat in 1896, one producing over three million barrels of oil in 36 days, and the other an even larger quantity. Prospecting has been carried on briskly, but with unsatisfactory results, one well having been sunk 861 ft. at Poota, and two others, 784 and 973 ft. respectively, at Hindar-Sindi (35 miles N. of Baku), without reaching paying oil, though surface indications and shallow trial drillings were favourable. Another well at Sompas reached a depth of 100 ft., and yielded a quantity of gas, but no oil, and at Koolakoo, on the Kaban river, six or eight wells have been sunk without any return.

The projected 8-in. pipe line (for refined oil) from Michailova to Batoum was to have been completed by October of the present year, but as the plant for making some of the pipe is only just erected at Mariopol, the line is not expected to be ready soon enough to influence materially the trade of 1897.

The Grosni field does not seem to be fulfilling expectations, as in January there were only 12 wells, yielding some 7,500 barrels per diem, seven new ones sinking, two being deepened, and eight new derricks. The largest of the two refineries near the railway station has only turned

out one cargo of refined oil, and the other one has not yet begun working.

Probably the Grosni oil, which gives only 15—18 per cent. of burning oil, and leaves a residuum too heavy for fuel, cannot compete with Baku oil; and possibly, Grosni being nearer the home markets, it is more profitable to sell the crude oil for fuel than to refine it.—C. S.

## IV.—COLOURING MATTERS AND DYES.

### PATENTS.

*Benzene and Monatomic Phenols, Action of Acid Chlorides on, in Presence of Ferric Chloride.* M. Nencki and E. Stoeber. Ber. 30, 1768—1772.

By mixing 5 parts by weight of benzene, 7 parts of benzoyl chloride, and gradually adding 7 parts of sublimed ferric chloride, a vigorous evolution of hydrochloric acid takes place, and finally the liquid solidifies to a mass of crystals. After washing with water and dilute hydrochloric acid, extracting with ether, and distilling off the latter, a fraction was obtained which was benzophenone. In a similar manner 7 parts of benzene, 8 parts of acetyl chloride, and 8 parts of ferric chloride give acetophenone. The phenols react like the hydrocarbons, and by mixing 5 parts of phenol with the same weight of carbon bisulphide, 6 parts of acetyl chloride, and slowly adding 7 parts of ferric chloride, *p*-oxyacetophenone is obtained, 100 grms. of phenol giving about 30 grms. of the ketone. The three isomeric cresols react in the same way. Thus *o*-cresol gives methoxyacetophenone having the constitution—

The product crystallises in flat prisms melting at 104° C. The *m*-cresol also gives an aceto-ketone sparingly soluble in water, which melts at 126° C. It is probable from analogy that the constitution is 1.3.6.C<sub>6</sub>H<sub>3</sub>.CH<sub>3</sub>(OH)COCH<sub>3</sub>. It is noteworthy that phenol and benzoyl chloride in presence of ferric chloride only give benzoic acid phenol ether. By the action of ferric chloride (8 parts) on a mixture of *p*-chlorophenol (6 parts) and acetyl chloride (8 parts), the authors obtained *p*-chloroxyacetophenone melting at 55° C. The product obtained from *o*-chlorophenol and acetyl chloride crystallised in needles melting at 96° C., and gave a hydrazone crystallising in yellow needles. By acting with ferric chloride (6 parts) on *o*-chlorophenol (5 parts),

and benzoyl chloride (6 parts), chloroxybenzophenone is obtained, which crystallises from alcohol in yellow needles melting at 176° C. In applying the same reaction to aromatic aldehydes, generally tarry, non-crystallisable products were obtained, but salicylic aldehyde yielded a dyestuff on slowly adding 1 part of ferric chloride to 4 parts of salicylic aldehyde. The product has probably the formula—

and was obtained by Bourquin (Ber. 17, 502), by the action of zinc chloride on salicylic aldehyde.—T. A. L.

**Dimethyl- $\alpha$ -naphthylamine, Some Derivatives of.** P. Friedländer and K. Lagodzinski. Mitt. des k.k. Tech. Gew. Museums, 1897, 7, 125—132.

DIMETHYL- $\alpha$ -NAPHTHYLAMINE was first obtained in 1870 by Landshof, by the action of methyl iodide on naphthylamine. Hantzsch, later, obtained a quantitative yield of it by heating the dry hydrochloride of the latter base with methyl alcohol. Monnet, Reverdin, and Nötting studied the action of mild oxidising agents upon it, with the object of preparing a compound analogous to Methyl Violet, but found that the base was in every instance decomposed without the formation of a dyestuff. Dobner, and Friedländer and Welms jointly, attempted, also unsuccessfully, to produce the naphthalene analogue of Malarine Green—the first named by treating the base with benzotrichloride, the latter two chemists by oxidising tetramethyl-diamidodiphenylmethane, which results from the action of benzaldehyde on the base. The latter, moreover, observed that hexamethyl-triamidotrinaphthylmethane, like the tetramethylamido compound mentioned, is decomposed when oxidised.

1.4-Amidodimethylnaphthylamine was obtained by Friedländer and Welms by the reduction of benzene-azodimethylnaphthylamine sulphonic acid. It may be also prepared by reducing the nitroso compound, which is formed by the action of nitrous acid on dimethyl- $\alpha$ -naphthylamine, and again (P. Cohn, Monatsh. f. Chem. 16, 798), by reducing tetramethyldiamido-azonaphthalene. It is an oil which rapidly oxidises on exposure to air.

Carbonyl chloride acts upon dimethyl- $\alpha$ -naphthylamine at the ordinary temperature, yielding a carboxylic acid, which, when treated with diazotised sulphanilic acid, loses carbon dioxide and gives an azo compound. This is also formed from dimethyl- $\alpha$ -naphthylamine and the same diazo compound. It would therefore appear that the carboxyl group occupies in the carboxylic acid the position para relatively to the dimethylamido group.

Bromine acts upon the base in acetic acid solution, giving a monobromo derivative. This does not combine with diazo salts, and hence would appear to be a para-substituted compound. It is an oil decomposing at 260°.

1.4-Dimethylamidonaphthol is obtained by alkali-fusion from 1.4-dimethylamidonaphthalene sulphonic acid. It forms long, colourless prisms (m. pt. 113°), which turn brown on exposure to air. It is sparingly soluble in water and ether, but dissolves readily in alcohol. It forms soluble compounds with acids and alkalis. Diazobenzene chloride acts upon it in an alkaline solution, forming a red-orange compound. Chromic acid colours its aqueous solution cherry-red, while ferric chloride is without characteristic action.

1.4-Dimethylamidonaphthol is not produced by the action of nitrous acid on the above-mentioned amido-dimethylnaphthylamine, but  $\alpha$ -naphthoquinone instead. The latter is also formed by the action of nitrous acid on an acidified solution of dimethylamidonaphthol.

Formaldehyde condenses with dimethyl- $\alpha$ -naphthylamine, giving tetramethyldiamido- $\alpha$ -dinaphthylmethane, a compound which crystallises in flat, colourless prisms (m. pt. 173°—174°, uncorr.). It dissolves with difficulty in alcohol and ether, but with ease in benzene and in aqueous solutions of acids, and it does not react with diazo salts.—E. B.

**1.5-Amidonaphthol.** P. Friedländer and K. Lagodzinski. Mitt. des k.k. Tech. Gew. Museums, 1897, 7, 130—131.

This compound is prepared, by fusion with caustic potash at 230°—235°, from the corresponding naphthylamine sul-

phonic acid, which is obtained by sulphonating  $\alpha$ -naphthylamine in the cold. It forms nearly colourless needles, melting with decomposition at 193° (uncorr.); does not yield a platinum-chloride double salt or a precipitate with stannous chloride and is coloured green by ferric chloride and bluish-red by chromic acid.—E. B.

**Aldehydes, Synthesis of Aromatic.** L. Gattermann and J. A. Koch. Ber. 30, 1622.

See under XXIV., page 832.

**Phenylphenazonium into Phenosafranine, and Nietzki and Ott's Isorosinduline into Naphthophenosafranine; Conversion of.** F. Kehrman and W. Schaposchinkoff. Ber. 30, 1565—1572.

WHEN the orange yellow alcoholic solution of acetylaphosafranine chloride is agitated for some time with aqueous ammonia in the air, the deep bluish violet colour of the solution finally turns magenta red and the solution contains acetylphenosafranine. On acidulation with hydrochloric acid and boiling, the acetyl group is split off, and on evaporating the alcohol, phenosafranine chloride crystallises out identical in every respect with that obtained from aniline and *p*-phenylene diamine. It has already been shown that the phenazonium salts are converted by ammonia in an alcoholic solution into aposafranine salts, and it is thus possible to convert, on the one hand, phenosafranine through aposafranine into phenazonium, and, conversely, the latter through aposafranine and its acetyl derivative into phenosafranine.

By heating together on the water-bath isorosinduline chloride with acetic anhydride and sodium acetate, an acetyl derivative is obtained which dissolves in water and alcohol with an orange-yellow colour and shows a strong yellowish fluorescence. It dissolves in strong sulphuric acid with a violet colour, and is in every respect similar to phenylphenazonium chloride. When the alcoholic solution is oxidised with air in presence of ammonia and subsequently hydrolysed with hydrochloric acid, a precipitate of naphthophenosafranine chloride is obtained which crystallises from alcohol in greenish granules. The crystals dissolve tolerably easily in water and alcohol with a bluish ponceau-red colour and show a strong orange-yellow fluorescence. They dissolve in concentrated sulphuric acid with a bluish-green colour, which on dilution turns dirty blue and finally rose-red. Naphthophenosafranine stands intermediate between phenosafranine and Magdala Red, but approaches more nearly to the former.

Since the acetyl derivatives of aposafranine and of isorosinduline behave towards alkalis and ammonia exactly like the salts of phenazonium and of naphthophenazonium (Ber. 29, 2316; this Journal, 1896, 802) it follows that these acetyl derivatives are azonium compounds, and have a constitution corresponding to the non-substituted azonium compounds, whilst acetyl-rosinduline cannot be directly amidised. This behaviour is at once evident if acetyl isorosinduline and acetyl rosinduline be regarded as derivatives of  $\beta$ -naphthoquinone, according to the following formula:—

Similarly, acetylaphosafranine has the following formula:—

which alone explains the conversion by ammonia into pheno-safranine.

Criticising Fischer and Hepp's paper (Ber. 30, 391; this Journal, 1897, 135), it is pointed out that the conclusion of the former as to the formula of methylpheno-safranine is incorrect; and, further, from information to be published later, there is reason to believe that the indones, as Nietzki assumes, inner anhydrides of *o*-quinonoid azonium compounds. With regard to the oxazine and thiazine dyestuffs, only those of the former which contain ammonium groups are strong bases. Thus the simplest Mella Blue obtained from  $\beta$ -naphthol and quinone dichlorimide is less basic than the corresponding eucharidine, whilst the isomeric phenomaphthazine with the imido group in the naphthalene ring is so feeble a base that it will not even give an acetate; but neither substance is to be compared at all, as regards basicity, either with rosinduline or with iserosindaline. The thiazine dyestuffs are tolerably strong bases, but for another reason. It has been found that the simplest thiazine corresponding to aposafranine, and having, according to Bernthsen, a *p*-quinonoid formula, can, like aposafranine, be diazotised, and gives azo compounds with phenols. Hence the thiazine dyestuffs may exist in a form corresponding to the azonium compounds, according to the following scheme:—

the pentavalent nitrogen being replaced by tetravalent sulphur. The bases free from oxygen, of the thiazines and the thiazones, however, still have most probably a *p*-quinonoid constitution, and in the oxazone series an *o*-quinonoid formula would require the assumption of tetravalent oxygen. It is pointed out finally that Fischer and Hepp subsequently confirmed (Ber. 29, 2760; this Journal, 1897, 132) Kehrman's observation (Ber. 29, 2316, *loc. cit.*) that naphthophenazonium is converted by alcoholic ammonia into rosinduline.—T. A. L.

*Rosanilines or Bases of the Corresponding Rosanilins, New Methods for Converting p-Nitrodiamidotriphenylmethane into.* M. Prud'homme. Bull. Soc. Chim. 1897, 654—659.

By heating together 1 gram. of *p*-nitrodiamidotriphenylmethane, 10 grms. of caustic soda (38°), 80 c.c. of water, and 160 grms. of alcohol (95° Tr.) in a flask furnished with a reflux condenser, a product is obtained which, by the action of reducing agents, is converted into *p*-rosaniline or into a corresponding base. The reduction may be effected in an acid or alkaline solution; according to the former method, by dissolving the product in dilute acetic acid, heating to boiling, and adding sodium sulphide, stannous chloride, or zinc dust. The shade passes from dirty violet to the characteristic red of *p*-rosaniline. If, instead of employing acetic acid, the product be dissolved in dilute hydrochloric or sulphuric acid and reduced in the cold with zinc dust, a colourless solution is obtained which contains the *p*-hydroxylamine of diamidotriphenylmethane. This, on boiling, is converted into triamidotriphenyl carbinol. If the reduction be carried out in an alkaline solution, the time of boiling varies with the nature of the reducing agent. The best yield is obtained by heating together, for about 12 hours, 1 gram. of the *p*-nitroleuco base, 8 grms. of crystallised sodium sulphide, 80 c.c. of water, and 160 grms. of alcohol. Only about 60 per cent. of the theoretical yield is, however, obtained. By employing the tetramethylated base it is possible to isolate two substances which are formed in the reaction, and the constitution of which may be expressed by the formulae given at the top of the next column. A mixture of 1 gram. of the tetramethylated leuco base, 10 grms. of caustic soda (38°), 80 c.c. of water, and 160 grms. of alcohol is heated together on the water-bath for about 1½ hours, or until the leuco base is completely dissolved. After filtering and standing 24 hours, the filtrate deposits

I.

II.

red crystals, whilst the mother-liquor, on standing for several days, yields yellow crystals. The red substance changes colour at 85° C., and is completely melted with partial decomposition at 100°—105° C., whilst the yellow crystals melt at 142°—143° C. The two compounds, when acted on by reducing agents, yield Tetramethyl-rosaniline Violet, and the same dyestuffs are produced from both by their action on phenols and amines. They differ, however, in respect to their behaviour to acids. The red substance dissolved in dilute mineral acids or concentrated acetic acid, more especially in presence of alcohol, gives a blue solution which dyes cotton mordanted with tannin or silk a greyish-blue. (On heating or standing, this solution turns yellowish-green. The yellow substance on the other hand, dissolves to an almost colourless solution, which only becomes coloured on heating, yielding the same green as the red substance. The author considers that formula I. corresponds to the yellow substance, whilst the red crystals are represented by formula II., and that the intermediate blue compound has the formula—

This subsequently loses water, yielding  $\text{Cl} \text{---} \text{C} = \text{C} (\text{C}_6\text{H}_4 \cdot \text{NR}_2)_3$ , and is thus a confirmation of Rosenstiel's formula for rosaniline. That the yellow substance is not at once coloured by dilute acids is probably due to the fact that the hydroxyl of diamidotriphenyl carbinol is less easily attacked than that of triamidotriphenyl carbinol, and it is known that the triphenyl carbinol is no longer capable of etherification.

—T. A. L.

*Cochineal Dyestuffs.*—II. C. Liebermann and H. Voswinkel. Ber. 30, 1731—1744.

THE authors confirm their formula,  $\text{C}_{10}\text{H}_5\text{O}_7$  and  $\text{C}_6\text{H}_5\text{O}_5$ , already given for cochenillic and coccic acid (Ber. 30, 688; this Journal, 1897, 474). They have further examined the tribromocresotic acid, which is obtained by treating cochenillic acid with bromine water. When acted on with sodium amalgam this acid is slowly converted into cresotic acid, melting at 210° C. This 1.3.5 cresotic acid is also obtained directly from cochenillic acid by heating for 2—3 hours with water to 200°—210° C. Since, moreover coccic acid has the composition of a cresol dicarboxylic acid, and is generally formed in the preparation of cochenillic acid, it appeared probable that this acid was an intermediate product of the decomposition of cochenillic acid, which was found to be actually the case. By heating cochenillic acid for 1 hour with water to 170° C., carbonic acid, cresotic acid, and coccic acid are obtained. The latter acid is identical with oxyvitic acid, and has the constitution 1.3.4.6. $\text{C}_6\text{H}_2(\text{CH}_3)_3\text{OH} \cdot (\text{CO}_2\text{H})_2$ . This acid is termed  $\sigma$  coccic acid, since an isomeric acid termed  $\beta$  has been obtained by repeated sublimation of cochenillic acid. Water and carbonic acid are given off and the anhydride of a dicarboxylic acid is formed, which on boiling with water, yields  $\beta$ -coccic acid, melting at 164° C. It has the constitution 1.3.5.6. $\text{C}_6\text{H}_2\text{CH}_3\text{OH} \cdot (\text{CO}_2\text{H})_2$ , whilst cochenillic acid is homohydroxyhemimellitic acid of the formula 1.2.4.5.6. $\text{C}_6\text{H}_2\text{CH}_3\text{OH} \cdot (\text{CO}_2\text{H})_3$ . With regard to the constitution of Carmine itself,  $\text{C}_{11}\text{H}_{15}\text{O}_6$ , the authors consider that it is probably a hydrindene derivative, and that its parent substance is diketohydrindene—

(from phthalic ester and acetic ester). This, as Wislicenus and Kötze (*Annalen*, 246, 347, 252, 72) have pointed out, is easily converted into a condensation product, probably—

which has the remarkable property of dissolving in cold dilute alkali with a red colour, and of dyeing wool red from a slightly acid bath, although it can in no sense be considered as a mordant dyestuff.—T. A. L.

#### PATENTS.

*Colouring Matters [Saccharofluorescein], Impts. in and relating to the Production of.* G. B. Ellis, London. From "La Société Chimique des Usines du Rhône," and G. P. Monnet et Cartier, Lyons, France. Eng. Pat. 21,197, Sept. 24, 1896.

Is a similar manner to that already described in Eng. Pat. 21,196 of 1896 (this Journal, 1897, 735), dyestuffs of the same class can be obtained by condensing saccharine with *m*-amidophenol or cresol, or with the mono- or dialkylated derivatives of these substances. For instance, 1 kilo. of diethyl-*m*-amidophenol is heated with twice its weight of saccharine (anhydrosulphamidobenzoic acid) for 36 hours to 165° C. The time of reaction may be considerably shortened by the use of condensing agents. When the reaction is complete, the melt is cooled, ground, and suspended in water containing at least 1 kilo. of sodium carbonate. After boiling up and filtering from dissolved saccharine (about half the weight of that taken), the insoluble residue is digested for several hours with caustic soda-lye. The insoluble powder is finally dissolved in water made strongly acid with hydrochloric acid. The boiling solution, after filtering, deposits on cooling small green crystals with a metallic reflex. The product in this condition is slightly soluble in water, giving a violet-red solution with a yellow fluorescence. When this solution is boiled, it becomes decolorised and deposits a violet flocculent precipitate. The colour reappears on the addition of an acid. A similar decomposition takes place on the addition of an alkali. The base, after recrystallisation from benzene, melts at 240°–215° C. The products are known as Sulpho-rhodamines.

—T. A. L.

*Colouring Matters [Anisolines], Impts. in and relating to the Manufacture of.* G. B. Ellis, London. From "La Société Chimique des Usines du Rhône," and G. P. Monnet et Cartier, Lyons, France. Eng. Pat. 21,198, Sept. 24, 1896.

The specification describes a novel method for alkylating Rhodamines by converting these latter into their acid chlorides, which react with alcohols, forming ethers or esters. The method consists in suspending the Rhodamine salt or its base in phosphorus oxychloride, chloroform, carbon bisulphide, or other indifferent solvent or diluent, and adding one molecular equivalent of phosphorus pentachloride. A brisk reaction takes place, and hydrochloric acid is evolved. The melt is finally boiled for some time under an inverted condenser and the chlorides of phosphorus are subsequently removed by distillation. The rhodamine chloride remains as a resinous mass with a brownish-red to greenish reflex. A purer product may be obtained by carrying out the reaction in the cold and precipitating the product with toluene. In order to convert it into an Anisoline the product is powdered and boiled with absolute alcohol when it gradually dissolves. After driving off the alcohol the crystalline product remaining may be purified by dissolving in water, adding sufficient hydrochloric acid to form the salt, and precipitating with salt.—T. A. L.

*Ortho- and Paranitrobenzylaniline and its Homologues, Manufacture of.* O. Imray, London. From "The Farbwerke vorm. Meister, Lucius, and Brüning," Hoechst a. M., Germany. Eng. Pat. 22,041, Oct. 3, 1896.

The action of chlorine or bromine on *o*- or *p*-nitrotoluene, with or without a halogen "carrier," gives under the best

conditions more than 50 per cent. of the corresponding nitrobenzyl chloride or bromide, but hitherto no satisfactory method has been known for obtaining the nitrobenzyl haloid in a pure state. By reacting with aniline or its homologues on the nitrobenzyl haloids, they are converted into bases of the general formula  $\text{C}_6\text{H}_4\text{N}(\text{H})\text{CH}_2\text{C}_6\text{H}_4\text{NO}_2$ . These on oxidation yield the corresponding nitrobenzylidene compounds  $\text{C}_6\text{H}_4\text{N} : \text{CH} : \text{C}_6\text{H}_4\text{NO}_2$ , which by the action of dilute mineral acids are converted into amides and nitrobenzaldehyde. The separation of the pure nitrobenzyl haloid is thus of great technical importance, and is carried out by heating to 85–90° C. with wet steam, in a copper or cast-iron boiler provided with a rapid agitator, about 300 kilos. of an *o*- or *p*-nitrotoluene chlorinated to about 50 per cent., corresponding to about 170 kilos. of *o*- or *p*-nitrobenzyl chloride, together with 190 kilos. of aniline, or the equivalent amount of teluidine or xylylidine. When the reaction has commenced, the temperature rises spontaneously to 120–180° C., according to whether aniline or one of its homologues has been employed. When the temperature falls, the reaction is complete, and after cooling to about 90° C., 300 litres of water are added, and the whole is boiled up, when the aniline hydrochloride dissolves and may be drawn off. The insoluble residue, consisting of nitrobenzylaniline and nitrotoluene, is distilled with steam, when the latter passes over, leaving nitrobenzylaniline, which may be purified by crystallisation from alcohol or by dissolving in dilute acids and reprecipitating. Nitrobenzyl bromide may be used in place of the chloride, and caustic alkali, alkaline carbonate or acetate, or an alkaline earth or ammonia may be substituted for the aniline; but in this case the addition of 50–100 litres of water is advisable.—T. A. L.

#### V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Tendering of Cotton Fibres by Acid during Sulphur Storing.* Mitt. aus den k. Versuchsamt. zu Berlin. 1897, 15, [2], 134–136.

Is a sample of flannel, in which the warp consisted of cotton and the weft of wool, it was noticed that the cotton had become tender, the wool not being affected. The tender parts had a yellow appearance, and crumbled on being touched. According to the report of the works, the webs were milled, washed twice, and bleached in the sulphur stove.

The destruction of the cotton was due to free sulphuric acid, of which there was a considerable quantity in the flannel. As the material itself could not contain any sulphuric acid, its presence must have been due to the sulphurous acid used in the bleaching, having become oxidised to sulphuric acid, the latter not having been washed out. On making a close search at the mill, an aperture was found in the sulphur stove, which admitted the air. The flannel made after closing this aperture was not tendered.—S. P. E.

#### PATENTS.

*Fibres and Fibrous or Textile Materials, Impts. in the Treatment of, to Improve the Appearance or Finish and Facilitate the Operation of Dyeing.* J. Schneider, Ashton-on-Mersey. Eng. Pat. 19,424, Sept. 2, 1896.

AN improvement in the mercerising process is described. The mercerising agent recommended is sodium or potassium sulphide, but caustic soda may be used. In either case an addition is made to the bath of a solvent for fatty matters; this may be alcohol, benzene, petroleum spirit, aniline, or turpentine. The fibre is stretched either during mercerising or immediately afterwards.—R. B. B.

*Silky or Similar Lustrous Effect, Impts. in the Production of, on Yarns, Threads, and Fabrics having a Vegetable Origin.* A. Liebmann, Manchester. Eng. Pat. 19,633, Sept. 5, 1896.

To obtain the desired effect, yarns or fabrics made from Egyptian or Sea Island cotton, slightly twisted and loosely doubled, are mercerised in caustic soda at 52° Tw. The

liquid is partially removed by squeezing, and the material subjected to stretching for 5–10 minutes, well washed with water, and released from tension. The appearance and softness of the fibre are enhanced by a subsequent treatment with soap or acetic acid.—R. B. B.

*Cotton, A Process for Giving a Silk-like Appearance to.* O. Seyfert, Glauchau, Saxony. Eng. Pat. 28,879, Dec. 16, 1896.

COTTON, mercerised with caustic soda in the usual manner, is dried at a low temperature (30°–40° C.), in a tightly stretched condition, and finally washed without tension.—R. B. B.

*Mercerising Vegetable Fibrous Substances, Impts. in or relating to, and in the Manufacture of Fabrics.* R. Thomas and E. Prevost, Crefeld, Germany. Eng. Pat. 20,714, Sept. 18, 1896.

THIS patent describes several modifications and extensions in Thomas and Prevost's previous patent (18,040 of 1895; this Journal, 1896, 804), relating to the mercerising of fibres and fabrics under tension. The extensions claimed are: (1) the treatment in a similar manner of vegetable fibres on cops, reels, or bobbins; (2) the fibrous substance is stretched beyond its original length during or immediately after the mercerising process, and is then washed without tension; (3) tightly twisted yarns and dense fabrics are washed with dilute acid or alkali, to neutralise the alkali or acid used for mercerising, instead of washing with water; (4) mercerised and non-mercerised yarns are woven together and the mixed fabric is dyed; (5) more dilute caustic soda may be employed, *viz.*, at 10°–20° B., if the temperature during mercerising is reduced to 6° C., the stretching being continued until the normal temperature is regained.—R. B. B.

*Textile and other Fabrics, Impts. in or relating to.* J. and H. Jelley, London. Eng. Pat. 23,588, Oct. 23, 1896.

IT is claimed that fabrics are toughened and made less easily penetrable by sharp objects when impregnated or coated with a mixture of turpentine and glycerin in naphtha or other solvent. The material thus obtained is stated to be specially suitable for pneumatic tyres.—R. B. B.

*Jute Bast, China Grass, Rhea, and like Plants; Impts. in the Treatment of, for Use in Textile Industries.* A. H. Prinz, Vienna, Austria. Eng. Pat. 11,804, May 12, 1897.

THE crude jute bast, &c., is loosened and freed from tips and root ends by well-known mechanical methods. A special chemical process then follows, consisting of four operations: (1) The fibres are macerated in the cold with caustic soda, *sp. gr.* 1.335. The liquors are used for three successive quantities of fibre, being made up to the original volume for this purpose. (2) Without washing, the fibres are exposed for 8–12 hours to the action of chlorine gas, and it is claimed that the incrustations are thereby converted into chlorine compounds, which are easily removed, after washing with water, by (3) a second treatment with caustic soda similar to the first. After again washing, the fibres are (4) bleached by means of hypochlorite of soda at 5° B. for 4–6 hours, and are allowed to remain in the bleaching vessel for 2–4 hours after drawing off the liquor. A final washing to remove chlorine completes the process.—R. B. B.

*Absorbent Material for Use in Making Boot Socks, Dress Shields, and other Articles of Clothing.* F. Boshardt, Manchester. From Rulle-Sulzer and Co., Glarus, Switzerland. Eng. Pat. 13,965, June 8, 1897.

SPONGE is reduced to fine particles, freed from sand and other foreign matter, washed in a dilute soda solution, and further torn up by mechanical means. A little hemp is added to the paste obtained, and the whole pressed into moulds, squeezed, and dried. The material is called "sponge wadding," and, when enclosed between layers of textile material, may be used for boot socks, &c. for the purpose of absorbing moisture and perspiration.—R. B. B.

*Bleaching and Disinfecting Fibrous Materials, Impts. in, and Apparatus for that Purpose.* V. Floquet and L. Bonnet, Rheims, France. Eng. Pat. 14,319, June 12, 1897.

IN order to obviate certain defects of the sulphur bleaching process due to contact with air, bleaching is carried on in a vessel from which the air has been exhausted. Sulphurous acid in liquid form is admitted, and acts—it is claimed—with great rapidity. When the action is complete the acid is pumped out, and water for washing is admitted.—R. B. B.

*Asbestos Fabric, Improved, and Process for the Production of the same.* R. Klinger, Gumpoldskirchen, Austria. Eng. Pat. 16,379, July 10, 1897.

ASBESTOS is divided into very fine fibres, of as great a length as possible, and immersed in an india-rubber solution, the whole being thoroughly mixed until each fibre appears coated with the solution; the solvent, *e.g.*, petroleum spirit, is then evaporated. The asbestos fibres will have become very adhesive, and the mass may be compressed or rolled into any desired form. The name given to the resulting material is "asbestos leather," and it is said to resemble leather in its properties and structure.—R. B. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Aniline Black on [Cotton] Knitting Yarn.* H. Weise. Leipziger Färber Zeit. 46, [7], 285–286.

A BLACK on cotton yarn, not turning greenish, and which does not rub off, is obtained as follows:—

1 kilo. of glue is softened, and subsequently dissolved in 10 litres of water, and then 3,600 grms. of "aniline salt" (aniline hydrochloride) are dissolved in it. In a second vessel, 600 grms. of sodium chlorate and 300 grms. of ammonium chloride are dissolved in 10 litres of hot water. In a third vessel, 150 grms. of copper sulphate are dissolved in 8 litres of water. When cold, these three solutions are united, and 2 litres of aluminium acetate solution (prepared as stated below) are added to the mixture.

The previously well-cleaned and dried yarn is twice impregnated with this solution in lots of 1 kilo., and aged at a temperature not exceeding 30° C. For developing 25 kilos. of yarn, 1,200 grms. of potassium bichromate are dissolved in a sufficiency of boiling water, and 100 grms. of "aniline salt" are added to the bath. The yarns are passed through this bath four times, and, after adding  $\frac{1}{4}$  litre of sulphuric acid, six times more, well rinsed, and finally soaped.—L. S.

*Woolen Cloth after Carbonising, Uneven Dyeing of.* K. Schimke. Färber Zeit. 8, [15], 233–234.

THE author calls attention to the difficulty of obtaining level shades with the dye-woods on woollen cloth from which every trace of acid has not been removed after carbonising. By careless work during the carbonising process, wool may be permanently injured for dyeing purposes, as such "acid stains" do not dye to the same depth of shade as the other parts.—L. S.

## PATENT.

*Dyeing, Finishing, Sizing, Washing, or similarly Treating Yarn: A New or Improved Machine for.* F. Davies, Blackburn, and A. Liebmam, Manchester. Eng. Pat. 21,492, Sept. 29, 1896.

THIS machine has primarily been designed for the imparting of a silky lustre on cotton yarn by mercerisation whilst in a stretched condition. Its essential features are a pair (or a number of pairs) of parallel rollers, to receive the hanks of yarn.

The bearings of the rollers are mounted in a slide block traversed by a screw, by actuating which, the distance between the rollers may be increased or diminished, so as to stretch the yarn.

Fig. 1 shows a transverse section; Fig. 2 a partial horizontal section of two contiguous lower rollers; and Fig. 3 a similar section of two upper rollers.

The yarn is arranged upon and around the rollers A, A', each lower roller rotating within a cistern B, which can be raised or lowered by the screw J, on which slides the block

B' carrying the brackets B<sup>1</sup> on which the cisterns rest. The rollers are mounted upon the through-shafts C, passing through a sliding block D, upon one side of which there is a projecting part having a vertical screw-threaded hole E, through which is passing the vertical screw D'. On the upper end of each of the screws there is fixed a worm wheel

II, with which gears a worm II<sup>1</sup>, fixed upon the shaft II<sup>2</sup>. By rotating this shaft in one or other direction, the upper rollers are raised or lowered, as the case may be.

The lower rollers A' are similarly mounted on the shafts C', passing through the stationary block G, and are geared together by spur wheels I, by which means they are made to revolve, the upper rollers being driven by the banks of yarn, which also serve as belts.

The banks of yarn having been arranged upon the rollers, the latter are set in motion, and the tanks are filled with the caustic soda "or other mercerising solution." When the mercerisation is complete, the lyc is allowed to run through valves into a reservoir, and the yarn is washed with water supplied in a spray by the perforated pipes Y, the water flowing into the tanks B, whence it escapes through an outlet.—I. S.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Solubility of Certain Easily Soluble Salts in Water at 16° C.* F. Mylius and R. Funk. Ber. 1897, 30, [12], 1716—1725.

The powdered salts were shaken for at least an hour with water at 18° C.; excess of salt was allowed to settle, the clear liquid drawn off with a pipette, weighed, and analysed.

In the table the solubility is expressed (A) by percentage of anhydrous salt in the solution, (B) by the weight of anhydrous salt dissolved by 100 c.c. of water, and (C) by the number of water molecules to one molecule of anhydrous salt.

For purposes of regularity in the last column, the formulae of salts of two monovalent constituents are doubled.

Magnesium iodate is known anhydrous and crystallised with 4 mols. of water. If the saturated solution be cooled to 0° and crystallisation effected by rubbing with a glass rod, the hydrate with 10H<sub>2</sub>O separates; this melts at 50°, and slowly decomposes at the ordinary temperature. The transition point is 13° C. Modifications with less than 4H<sub>2</sub>O are obtained by heating saturated solutions; these and the anhydrous salt are "insoluble" at the ordinary temperature, but dissolve in time after hydration.

Calcium iodate exists in the forms Ca(IO<sub>3</sub>)<sub>2</sub> + 6H<sub>2</sub>O and Ca(IO<sub>3</sub>)<sub>2</sub> + 11H<sub>2</sub>O; the solubility curves cut at 32°. The existence of the hydrate with 4H<sub>2</sub>O was not confirmed.

Salt.	Stable Form in Solution at 18°.	Specific Gravity of Saturated Solution.	A.	B.	C.
Lithium chloride	(LiClO <sub>2</sub> ) <sub>2</sub>	1.815	75.80	313.50	3.2

—A. C. W.

*Salt-Cake Furnaces, Measuring the Temperature of.* G. Schüler. *Zeits. f. angew. Chem.* 1897, **12**, 361—364.

At the present time the correctness of the temperature at which a salt-cake furnace is worked is judged either by the appearance of the muffle or, where the pot is heated by the gases leaving the muffle, by the length of time in which the material in the pot becomes stiff. Neither of these methods is sufficiently satisfactory, especially when the close connection between the life of the muffle and the temperature to which it is heated, are taken into account. The author has therefore attempted to measure the temperature pyrometrically. He recommends the use of the Seger standard cones, the fusion of which is not a physical but a pyrochemical process (this *Journal*, 1894, 762).

The method of using is simple. A firebrick is covered with powdered fireclay, and the cones—say Nos. 1, 2, and 3—are pressed into this. The whole is then placed in that part of the furnace, the temperature measurement of which is desired, and is allowed to remain there for any desired time (24 hours).

The author chooses as point of observation that angle of the lower flue into which the hot gases fall from above. This place is easily reached through the cleaning holes; it is the hottest spot beneath the hearth, and, on account of the mixing of the gases caused by their change of direction, a mean heat is fairly certain to be attained. The cones must not be in any way protected from the direct flames, these also playing upon the firebrick. The fine dust has no influence on the test. The observation consists in noting which is the cone fusible with most difficulty, that melts during the period of observation. Each cone, the apex of which bending over touches the supporting plate, is to be considered melted. The results obtained are very sharp. From his observations the author concludes that the temperature to be maintained at the above point of observation should lie between the fusion points of cones 1 and 2; it should certainly not fall below 02 or rise above 3; that is, it should be 1,150°, with a range of from 1,100° to 1,200°. New hearths may be heated somewhat higher; the temperature will also vary according to the salt cake production.

Regarding the kind of fireclay best suited for muffles, the author points out that the fire-resisting qualities are not the only ones to be considered. Not even the worst fireclay fuses at so low a temperature as cones 4 and 5, and yet many hearths are ruined at temperatures far below this point—in fact, below 900° C., since this temperature is above the fusing point of sodium sulphate. The burning of the hearth is thus not merely a question of the fusibility of the fireclay employed, but is to be ascribed to the greater fusibility produced in the mass by the gradual diffusion of the sulphate through the pores of the clay; and the use is therefore recommended of firebricks as non-porous as possible without injury to fire-resisting properties.—J. T. C.

*Waste Acid from Metal Works.* Public Health Engineer, Oct. 2, 1897, 415.

See under X., page 801.

### PATENTS.

*Carbonic Acid, Process and Apparatus for Purifying.* I. Quirin, Cologne, Prussia. Eng. Pat. 18,468, Aug. 20, 1896.

PURE carbonic acid is strongly compressed in contact with water containing an oxidiser, such as potassium permanganate, in solution; dissolved gases, other than carbonic acid, are expelled either by passage of pure carbonic acid or by diminution of pressure; and, finally, the dissolved carbonic acid is released "by pressure diminution or by use of vacuum." "The water makes a continuous circuit through the whole apparatus employed, being saturated in the absorber with the carbonic acid, and freed in the purifier from foreign gases, in order to separate in the gas-remover the purified carbonic acid."—E. S.

*Detergent and Bleaching Compounds, Impts. in the Manufacture and Treatment of, and in Apparatus employed therein.* J. Hargreaves, Widnes, and R. Armstrong, Preston, Lancaster. Eng. Pat. 18,589, Aug. 22, 1896.

THE sodium carbonate required for the preparation of detergent compounds is derived either from "vat liquor" of the Le Blanc process; from solutions obtained by the electrolytic decomposition of sodium chloride; or from mother-liquors occurring in the manufacture of sodium carbonates, processes being described adapted to each case. When caustic soda is present, it may be carbonated, according to one method, by addition of excess of sodium bicarbonate. A soluble detergent compound is obtained by incorporating monohydrated sodium carbonate with a strong solution of sodium carbonate at about 80° F., and then adding suitable oils, fats, fatty acids, resin, or the "niger" occurring in the manufacture of soap; but when "niger" is used any caustic alkali present is neutralised with acid fat or with sodium bicarbonate. The following is given as the approximate composition of an efficient compound:—Sodium carbonate, 50 parts; water, 35 parts; soap (estimated as fatty acids), 15 parts. To give bleaching properties, a small proportion of sodium hypochlorite is added, combined with oil of camphor, during or subsequent to the pulverising of the compound in the production of detergent powders.—E. S.

*Chlorine Gas, Improved Means for Effecting the Absorption of; applicable in the Manufacture of Chlorates and Bleaching Liquor.* W. R. Clarke and The United Alkali Company, Ltd., Liverpool. Eng. Pat. 20,068, Sept. 10, 1896.

DILUTE chlorine, such as that produced in the Deacon process, is led up a high tower fitted with baffle plates,

down which milk of lime or magnesia is caused to flow. The gases taken from the top are led up a second similar tower, in which they meet fresh milk of lime, which usually suffices to absorb practically all the chlorine; but additional towers may be used if necessary. The liquid flows from the bottom of the towers into troughs having plug holes, whence it flows into tanks provided with agitators, each tower having its own system of pumps and vessels. From the tank belonging to the first tower, the liquid is passed through a coil of piping immersed in a cold-water tank, and is thence forced to the top of the tower, the process being repeated as often as necessary. When the liquid passing through the first tower has absorbed sufficient chlorine, it is replaced by the partially saturated liquid from the second tower, which, in turn, is supplied with fresh liquid. For the manufacture of chlorates, the milk of lime or of magnesia may be of such concentration as to give a finished liquor of 50° to 60° Tw.; but if bleaching liquor is to be made the milk of lime must not be fully saturated with chlorine, and should test about 7° Tw.—E. S.

*Tartaric Acid and Tartrates, Process for Obtaining.* A. Schmitz and E. C. W. Toenges, Düsseldorf, Prussia. Eng. Pat. 21,178, Sept. 24, 1896.

ARGOLS, or other crude tartars, are boiled with an alkali carbonate solution in slight excess, and the warmed lye is treated with sodium hypochlorite until the brown colour of the liquid changes to a light vinous yellow; hydrochloric or acetic acid is then added until the reaction is neutral. The solution is precipitated by calcium chloride, the calcium tartrate separated, is boiled for some hours with sodium carbonate solution in slight excess, and the solution is treated with hypochlorite and neutralised as before. Pure calcium tartrate is then thrown down by calcium chloride, and may be decomposed in the usual manner to obtain tartaric acid. When it is desired to obtain cream of tartar, the calcium tartrate, first obtained as described, is boiled with potassium carbonate solution, and after separating the calcium carbonate, the liquid is treated with a little hypochlorite, and acid potassium tartrate is thrown down by addition of a suitable acid. The claim is for the obtaining of "tartrate of lime from raw products, partly manufactured substances, by-products, and refuse containing tartaric acid and tartrates" by the process described.—E. S.

*Salt, Impts. in the Manufacture of, from Brine, and in Apparatus therefor.* J. W. Weston, Thurcaston, Eurlinton, and T. I. Weston, Wickham Bishops, Essex. Eng. Pat. 23,614, Oct. 23, 1896.

In order to obtain small bright crystals of salt, brine is spread in thin films, which are not allowed to evaporate to dryness, the crystals being separated from the mother-liquor by mechanical means. The boiler shown, is open at the top, has vertical sides and ends, and a bottom inclined towards two pockets for removing deposited salt. A hollow cylinder, partly immersed in the liquid, takes up as it rotates a film of the brine, the crystals formed during rotation being removed by a scraper into pockets, whence they are withdrawn by suitable apparatus. A fireplace below the boiler communicates with surrounding flues and with a flue traversing the brine, part of the fire-gases being led through the revolving cylinder. The crystals obtained are centrifugally drained and then dried.—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

*China, Manufacture of Limoges.* U.S. Consular Reports, 1897, 54, [202], 426–430.

*Kaolin and Clays.*—The body of the china consists principally of felspar and kaolin, a certain proportion of ground china being sometimes added. One of the features of Limoges glazes is the entire absence of lead. The kaolin used is that obtained from the very pure deposits which occur in the quarries around St. Yrieix, Haute Vienne; to this kaolin the formula  $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 + 2\text{H}_2\text{O}$  may be ascribed. Most of the deposits occurring in other parts of France and in Great Britain contain more or less water, iron, mica,

magnesium, and often sulphur; and an excess of the first-named is extremely injurious in making the delicate paste used by Limoges potters. The inferior grades of china are frequently prepared by mixing the cheaper and impure clays with the pure kaolin. The kaolin is washed and ground, and all impurities removed before delivery at the works, where it is again washed. The liquid paste is passed between two electro-magnets, to remove all traces of iron, as the latter discolours the china, frequently by the formation of black spots. The superfluous water is then forced out of the clay, and the latter is twice subjected to the action of heavy zinc-covered cast-iron cylinders running over a zinc-covered table; this operation gives the requisite plasticity and evenness to the paste.

*Machinery.*—The machines are so arranged as to form several kinds of moulds. For plates, saucers, &c., three machines are used—one for reducing the paste to the desired thickness, the second for throwing the paste on to the moulds, and the third for finishing the article. Two machines are used for hollow ware, and the gauge, which has a side as well as a down-motion, is arranged so as to fit both hollow and curved ware. For oblong platters, &c., the jigger has one long and one short motion of the eccentric. An improved cup-making machine is now used, which has not only the down-motion, but also the gradual side-motion corresponding to the movement of the human hand.

*Firing.*—The method of firing is different from that used by American and British potters, as the latter make a very hard bisque and a very soft glaze, whilst in the manufacture of Limoges china the reverse is the case. Up to the year 1895, the down-draught furnace system, with kilns built in two storeys, was used; but within the past two years, smaller, single-storey kilns have been employed. The latter are fired in a continuous manner by a system of flues connecting each kiln with the others at the top and bottom, and the waste heat, after passing through the whole series of kilns, escapes from the last one into the chimney. With this system, only half the amount of fuel is required to produce the same degree of heat, and the china is better fired in less than half the time required by the down-draught system.

*Decoration.*—The design is drawn upon stone in the same manner as a chromo-lithograph, each colour having a separate stone. The powdered colour is sprinkled on the paper after it has received the impression from the stone. Only that portion which should receive the given colour is impressed, so that after the different paints are passed upon the sheets called for by the design, the sheet is ready for transferring. To prevent lead-poisoning, the powdering is done under cover. The tops of the tables are in glass, the backs and sides are made of wood, but the front is of cloth, in which are armbolts fitted with elastic bands, so that the hands can be thrust through and the powdering done without the danger of inhaling the dry colours. The work is seen through the glass top. The muffles are of two kinds. In the first, the firing is done with wood, and there is a space between the outside and the inside lining to protect the decorated ware from the smoke and impurities during combustion.—A. S.

*Brick, Vitrified, as a Paving Material.* J. W. Sibley. Eng. and Mining J. 1897, 64, [7], 187.

See under IX., page 800.

## PATENTS.

*Permanent Photographs on China and other Vitreous Surfaces, A New or Improved Method or Process of Producing.* J. Slater, Burslem. Eng. Pat. 21,981, Sept. 23, 1896.

See under XXI., page 825.

*Glass, Porcelain, Enamel, or Metal: Impts. in or appertaining to a Process for the Production of White, Black, or Coloured Pictures, Writing, or the like on.* F. Albrecht, Liverpool. Eng. Pat. 8890, Aug. 14, 1897.

This is a modification of the inventor's Eng. Pats. 13,838 of 1893 and 24,283 of 1895, for ornamenting glass, &c. The

invention consists in mating gold leaf, powdered metals, or other substances to the surface of glass by means of a menstruum composed of 60 grms. of precipitated silica, or the equivalent amount of  $\text{SiO}_2$  in the form of hydrate, in 1 pint of commercial silicate of soda solution. The use of other alkaline silicates in place of silicate of soda is, however, also claimed, and particularly the double silicate of soda and potash, though, in this case, a smaller proportion of silica is used. The material with which it is desired to decorate, is either mixed with the menstruum and so applied, or the menstruum is first applied and the colour afterwards dusted over. After pressing, the articles are stove at a temperature of about 1,500° F.—H. H. B. S.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Cement Admixtures, Report of the Cement Trade Section of the London Chamber of Commerce on, with Reports and Evidence of Experts.* 1897, 1—197.

An investigation into the admixture of foreign substances with Portland cement has recently been carried out under the auspices of the Cement Trade Section of the London Chamber of Commerce, who now issue a very complete report upon the subject. The Section record their belief that the practice of mixing materials with Portland cement after calcination does not prevail extensively on either the Thames or the Medway, and that, where it is practised, such admixture is, with the exception of gypsum, confined almost entirely to Kentish rag-stone. They believe, however, that a considerable quantity of iron furnace slag is, at the present time, being mixed with cement of British manufacture, though not by either Thames or Medway makers.

The possibility of the interaction of rag-stone and cement resolves itself into the question as to whether such mixtures show any tendency to lose carbonic anhydride on keeping. The experiments show that, instead of this being the case, such mixtures actually show a slight gain, due to absorption of carbonic acid from the air. Other conclusions arrived at are as follows:—Mixtures of rag-stone and cement have a specific gravity lower than that of unmixed cement, and indeed correspond closely with that calculated from the respective specific gravities of the two materials. With fresh cement, admixture of rag-stone tends to cause a prolongation of the setting-time, but this effect is not necessarily permanent, and the alteration of setting-time on keeping is more irregular than that taking place in unmixed cement. Mixtures of cement with 10 or 20 per cent. of rag-stone show the same slight expansion when the test-bar is kept in water as does unmixed cement; 50 per cent. mixture expands somewhat less. Mixtures of cement with 10, 20, and 50 per cent. of rag-stone, contrast to the same slight extent as unmixed cement when the test-bar is kept in air. Cement which is not overlimed and is well matured is not improved by the addition of rag-stone. None of the mixtures of rag-stone and well-matured cement which have been examined, has proved equal in strength to the unmixed cement. Mixtures of rag-stone and cement, when exposed to a red heat and subsequently slaked with water, disintegrate more readily than does unmixed cement.

A definition of Portland cement has been proposed, and a rule adopted, by the Cement Trade Section; to these all makers in Great Britain and Ireland are invited to subscribe, in the following terms:—

Resolved,—That Portland cement be defined as a mixture of two or more suitable materials, intimately and artificially mixed in the requisite proportions, and afterwards properly calcined and ground, to which nothing has been added during or after calcination, excepting that an addition, not exceeding 2 per cent. of gypsum, is permissible for the purpose of regulating the setting. That if any material whatever, excepting an amount not exceeding 2 per cent. of gypsum for the purpose of regulating the setting, be added to the Portland cement clinker during or after calcination, the article so produced shall not be sold as Portland cement, but under some other distinctive name.

—H. H. B. S.

*Brick, Vitrified, as a Paving Material.* J. W. Sibley. Eng. and Mining J. 1897, 64, [7], 187.

It is stated that, by the use of vitrified brick, a pavement is obtained which will successfully resist the wear and tear of the horse-shoes, is non-absorbent, easily repaired, may be cleaned by washing or sweeping, and will present a smooth surface, even when the brick is worn half through.—A. S.

## PATENTS.

*Wood and other Cellular or Fibrous Substances, Improved [Electro-capillary] Process and Apparatus for Treating or Saturating with Liquids.* L. A. Bretonneau and A. L. C. Nodon, Paris, France. Eng. Pat. 13,242, May 28, 1897.

See under XI. A., page 807.

*Artificial Stone, A New or Improved Manufacture of.* P. Kleber, Saarbrücken, Germany. Eng. Pat. 20,612, Aug. 14, 1897.

This invention consists in the production of an artificial stone which is not affected by atmospheric conditions. A dry mixture is made of sifted ashes, potash, and other alkaline carbonates, gypsum, and slaked lime. This is further mixed with dilute sulphuric acid and hydrated sulphate of lime, with the result that potassium sulphate is formed, which dissolves, and a plastic, pliable mass of gypsum is left, which is moulded by compression into the desired forms. With the view of getting rid of any alkali that may remain in the stone, it is finally immersed in a solution of alum acidified with sulphuric acid. The alum is decomposed and alumina formed, and this still further hardens the stone.—H. H. B. S.

*Artificial and other Stone Roofing, and other Tiles, and Enamel; Impts. in the Manufacture and Treatment of, and in Apparatus therefor.* G. F. Thomson, Wellingborough. Eng. Pat. 18,622, Aug. 21, 1897.

BLAST-FURNACE slag, ashes, clay, sand, or other waste or cheap material is mixed with dilute sulphuric acid, and the mixture allowed to stand for some time. Solution of sodium hydrate, carbonate, or silicate is then added, and the whole stirred from time to time; or, in some cases, it is boiled with soda. The solution is then drained off, and the residue run into moulds to dry. The stone thus prepared is surface-hardened and whitened by immersion, first in dilute sulphuric acid, and afterwards in solution of silicate of soda or sodium carbonate, after which it may be polished. For imitating marbles, suitable colours are added to separate portions, which are then poured simultaneously into the moulds. The construction of a mould for casting slabs, &c. is also claimed. This consists of a frame with removable sides, and divided into partitions by plates fitting into grooves.—H. H. B. S.

*Enamelling of Fireclay Baths and other Articles, Impts. in or connected with the.* W. Cliff, Leeds. Eng. Pat. 16,528, Aug. 28, 1897.

FIRECLAY baths or other articles are enamelled on the inside with a hard glaze, and, after firing, are coated on the outside with a softer glaze or spirit varnish, which is then hardened by stoving at a much lower temperature. The advantages claimed are, first, that the glaze and the bath are less liable to crack, and secondly, that by glazing in this way, baths can be decorated in any desired tint, which is not always possible when a hard glaze is used on the outside.—H. H. B. S.

*Cement, Slurry, Liquid Clay, and other Substances in like Condition. Improved Means applicable for Use in Drying.* G. G. M. Hardingham, London. From F. D. Cummer, Cleveland, Ohio, U.S. Eng. Pat. 20,603, Sept. 17, 1896.

THE process of drying slurry is apt to be troublesome, owing to clogging of the apparatus. The inventor surmounts this difficulty by adding a dry dust or powder (consisting of material of a character similar to that of the material of the slurry) in such quantity that the mixture does not adhere to the drying apparatus.—V. C.

*Artificial Stone for Grinding or Abrading Purposes.* Impts. in. C. C. Schirm and O. Lessing, Berlin, Germany. Eng. Pat. 11,630, Sept. 29, 1897.

SAND, pulverised quartz, emery, or similar substance, according to the purpose in view, is mixed with a flux of suitable hardness, such as glass-flux or fluor spar, and the whole heated to the fusing point of the flux. According to the quantity of flux used, the grains of the grinding agent can either be united at their points of contact only, or they can be entirely embedded; thus, the degree of porosity can be suited to the grinding requirements.—H. H. B. S.

## X.—METALLURGY.

*Steel, The Diffusion of Sulphides through.* E. D. Campbell. Iron and Steel Institute, Autumn Meeting, 1897.

THE author describes his recent experiments (this Journal, 1896, 906) on the diffusion of sulphides of iron, copper, &c., through solid steel, from which he concluded that the diffusion was dependent upon the presence of oxysulphide of iron, which by its great mobility was able to penetrate the pores of the metal. In the oxysulphide prepared for those experiments the ratio of FeS to FeO was practically 4:3, and the diffusion was complete. An oxysulphide having a crystalline structure has now been prepared, having the same ratio of FeS to FeO, by mixing ordinary sulphide of iron containing 26.3 per cent. of sulphur with 40 per cent. of its weight of precipitated magnetic oxide of iron, melting, and heating for 10 minutes in a porcelain crucible. On placing some of the crystalline pieces in the hole in the steel and heating as in the previous experiments, it was found that practically no diffusion took place, the oxysulphide simply having melted. Other attempts to make a pure diffusing oxysulphide resulted in the production of over 40 different specimens, none of which diffused completely as the original oxysulphide of the early experiments did, although some of them partly diffused. The conditions, whether chemical or physical, which govern the diffusibility or otherwise of the oxysulphide are not determined.—A. W.

*Carbon and Iron.* E. H. Saniter. Iron and Steel Institute, Autumn Meeting, 1897.

THE experiments are considered under four headings:—

(1.) *The thermal treatment of Fe<sub>3</sub>C.*—When Fe<sub>3</sub>C is heated to 800° C. and slowly cooled, or to 1,000° and chilled in water, the molecular ratio of combined carbon to iron remains practically unaltered, and very little graphite is formed. When heated to 1,000° and slowly cooled much graphite is formed, whilst when fused in magnesia in an atmosphere of carbon monoxide to about 1,100°, and slowly cooled, there is a loss of total carbon, and the greater portion of what remains is graphitic.

(2.) *The saturation point of iron with carbon by fusion in contact with excess of carbon.*—The presence of silicon increases the formation of graphitic carbon in saturated carbon-iron compounds, and endeavours were therefore made to obtain a carbide free from silicon. The saturation point obtained was 4.81 per cent. of carbon in an iron containing 0.04 per cent. of silicon, which latter can hardly reduce the saturation point to any great extent.

(3.) *The saturation point of iron with carbon by heating without fusion in contact with excess of carbon.*—Pure iron wire was heated to about 900° C. in a porcelain tube full of charcoal for three periods of seven hours each. The percentages of carbon absorbed in each period were 1.64, 1.15, and 0.16, and the saturation point is therefore put down at 2.95 per cent., of which amount 0.53 per cent. was graphitic.

(4.) *The etching of pure carbon-iron alloys at a red heat, in order to ascertain their structure at that temperature by means of the microscope.*—The steel was polished as usual and etched by dropping it into fused calcium chloride kept at a bright red heat in a platinum crucible. After the steel had attained this temperature the whole was heated for a further 15 seconds, and then cooled by dipping into cold water. The steel was washed with water and dried in alcohol. It would appear that the cementite is first dis-

solved bodily until a certain amount of oxide of iron is floating in the fused chloride. The carbon then begins to be removed without further solution of iron, probably by the action of the floating oxide. When the carbon is nearly all removed the iron is again rapidly dissolved. The etching was stopped before the end of the first period, *i.e.*, while both carbon and iron were being dissolved. The appearance of acicular crystals in some of the plates examined, is considered an indication of a definite carbide of iron existing in steel at a bright red heat, and if the carbon is retained by chilling in the form in which it exists at this temperature, these crystals would appear to be the hardening carbide. In its bearing upon Osmond's theory of  $\beta$ -iron, the author thinks that the crystals do not support it while at the same time they do not disprove it. If the acicular structure were an indication of allotropic hard iron it would exist with 0.1 per cent. carbon-steel as with 1.8 per cent., but it is entirely absent. Iron containing 1.0 per cent. of carbon has a totally different structure at a bright red heat to iron containing 0.1 per cent. of carbon, and the same difference exists in corresponding chilled steels, which differences must be due to carbon, and which may be considered as evidence in favour of the hardening of steel being due to a carbide of iron of great hardness.—A. W.

*Waste Acid from Metal Works: Report to the Sanitary Committee of the Worcestershire County Council, by Dr. G. H. Fosbrooke, Medical Officer of Health.* Public Health Engineer, Oct. 1897, 415—417.

### 1. INTRODUCTION.

2. Explains that the "acid" above referred to is a trade effluent from galvanising works, and is used in the process of covering iron with a coating of zinc. It is applied to sheet-iron, iron wire and netting, iron pipes, tubes, &c. At large works the sheets are rolled, and the wire is drawn as well as galvanised.

3. The preparation of the iron consists in cleaning the surface by dipping the articles into an acid bath. This is called "pickling," and the acid bath is technically called "pickle."

4. The pickle usually consists of muriatic (hydrochloric) acid properly diluted, and is generally used cold. At some works, dilute, hot sulphuric acid is employed. On being removed from the acid the articles are allowed to drain, and then washed with water, sometimes containing a little lime; this water is technically known as "wash water" as distinct from "pickle."

5. The object of this pickling iron is to remove the oxide on its surface, and to cause the metal to alloy with the commercial zinc, known as "spelter."

6. Thus the pickling process may give rise to a waste pickle containing either ferrous chloride or ferrous sulphate.

7. Hydrochloric acid is preferred by the great majority of Worcestershire manufacturers, not only because it is cheaper than sulphuric, bulk for bulk, but also because the latter attacks the metal too quickly.

8. After use the waste pickle often contains about one-third of the acid added at the commencement of the process.

9. Many works have been visited in various counties and many medical officers of health and analytical chemists have been communicated with, in order to ascertain "the extent to which acid turned into streams is injurious to health"; and it was found that there is a general consensus of opinion among such officials that there is no evidence to support the view that "acid turned into streams is injurious to health."

10. Through the courtesy of the 17 manufacturers in the galvanising trade in Worcestershire, it is ascertained that at the present time they employ about 3,500 men, and utilise 1,053 carboys (cwt.) of acid (corresponding to some 3,900 cwt. or 27,000 galls. of waste pickle) on an average every week.

11. Comparatively few manufacturers in this country treat their "waste pickle"; some, however, tip it on to cinder heaps, or throw it down disused pit shafts, while others discharge it directly into the River Stour, which from time to time consequently manifests a characteristic ochreous hue.

12. With regard to the effect of pickle in its crude state upon sewers and sewage, it is found that brick sewers at Birmingham have fallen in at two points where such waste liquor has been discharged for a length of time, owing to the action of the acid upon the mortar, and that the Wolverhampton sewers have also been injured.

14. Mr. Jones, county analyst for Staffordshire, states that at Wolverhampton the enormous quantity of iron in the pickle which reached the sewers at a time when the sewage was dealt with by irrigation alone, greatly interfered with the sewage treatment; coming, as it did, with intermittent rushes, the sewage was at times so loaded with iron in solution as to be quite poisonous to vegetation. To counteract this Mr. Jones advocated lime treatment of the sewage at the farm, but it having been found difficult to adjust, owing to the intermittent rushes of acid, the Corporation took steps to prevent the manufacturers putting untreated pickle into the sewers. On the other hand, Mr. Jones is of opinion that, provided muriatic pickle be properly treated before being added to the sewage, the sewers cannot be injured, and the sewage itself is improved.

16. Where sulphuric acid is used, the pickle is not entirely a waste product, as manufacturers get some return by recovering the sulphate of iron. The process consists in passing the hot pickle into wooden troughs (lined with sheet lead) containing pieces of board, upon which the sulphate of iron crystallises as the pickle cools; the crystals are collected for sale, and the effluent is then run off.

17. Mr. Ernest P. Peyton, in his pamphlet on "Pickling or cleaning iron, with recovery of Sulphate of Iron," writes:

The hot pickling solution passes slowly along the (crystallising) channel, cools on its way, and a large part of the sulphate of iron it contains is there deposited as crystals.

The cold mother-liquor containing the unexhausted sulphuric acid overflows from the crystallising channel, and is conducted and returned to the pickling vat.

18. The value of such crystals (ferrous sulphate) varies, according to quality and local demands, from about 12s. to 20s. per ton. Commercial sulphuric acid (common brown) is at the present time about 1*l.* per ton; and as 22 carboys (ewt.) of sulphuric acid should yield about 5 tons of crystals, it is obvious that the recovery of crystals would (at the rate of 15s. per ton) give a return of 3*l.* 15s. as compared with an outlay of 1*l.* 8s. for acid. For this reason, and on account of the facility with which sulphuric acid waste can be dealt with, it has been proposed to substitute sulphuric acid for hydrochloric in galvanising.

19. But in some cases it is merely necessary to cleanse the surface of the metal, whilst in others a scale of oxide of iron, formed by exposure to very high temperature, has to be removed, and in this latter case, the use of hydrochloric acid is imperative.

20. Where hydrochloric acid is used, in but one process is any claim made that treatment of the pickle is attended with financial success.

21. This is "Turner's process." Turner patented it, and subsequently disposed of the patent rights to Messrs. Walker Bros., Walkall, who have worked it for the past seven years, and are the only manufacturers who now carry it out.

22. In "Turner's process" the acid liquor is made to flow slowly on the heated bed of a reverberatory furnace with access to air, when it is decomposed, with liberation of hydrochloric acid and formation of ferric oxide, the latter of which can be used as a colour, or as "fetting" in furnaces. The hydrochloric acid is condensed in towers, collected, and used over again in the pickling vats. The district medical officer where this process is being tried states that some effluvia nuisance results therefrom.

23. The working account for 1896, issued by Messrs. Walker, shows a favourable balance; in this statement, however, the "oxide recovered" is quoted at 4s. per ton, whereas it is understood that in other localities this product is of little or no value.

27. It appears that Messrs. Walker's two furnaces evaporate about 25 tons per week. It is found, however, that of the 17 manufacturers in Worcestershire only two use more

than 3 tons per week; consequently, as very small furnaces would have to be put down, there is little doubt that these would scarcely pay. Furthermore, if the pickle were collected from the various works and conveyed to a central furnace, the cost of carriage would no doubt preclude financial success.

28. Although "Turner's process" has been known for some years past, and many manufacturers in the country have been required to deal with their "pickle," still it has not been generally adopted.

29. The simplest and most effectual means available for preventing the pollution of streams, or injury to sewers, appears to be to neutralise the spent pickle at the works with an alkali, which disposes of the free acid and precipitates the oxide of iron. Lime is generally preferred for this purpose, owing to the facility with which it can be obtained at moderate cost. One firm in Yorkshire contemplates neutralising the waste pickle with soda, and another with ammonia, but in neither instance is such treatment yet in operation, although it will probably be so in a few weeks.

30. The lime method consists in adding best lime (in the form of "milk") to the waste pickle (collected in underground tanks) until there is a slight alkaline reaction, and then thoroughly mixing. This mixture is then allowed to settle, and subsequently the supernatant liquor is run off, and the sludge pumped up and passed through filter presses.

31. If the neutralisation be properly managed, the oxide of iron sludge will be deposited, and the effluent liquor will neither contain acid nor alkali in excess, and be fit to discharge into streams or sewers.

32. The pressed sludge has then to be removed, and this is a matter of no small cost to manufacturers who carry on large works in populous localities.

33. In attempting to ascertain particulars of what the cost of such treatment is, it was found that, with one exception, those who use it keep no such records.

34. Messrs. Johnson (Ambergate, Derbyshire) at one time sold their pressed sludge at 4s. per ton, for mixing with sawdust to purify gas; but the demand is limited and fast decreasing. In fact, there is no doubt the lime process cannot be made to pay, although it enables manufacturers, often at considerable cost, to render their waste pickle fit to be discharged into streams or sewers, without detriment to anybody or anything.

35. Mr. Adolphe Crosbie (Wolverhampton) states that the question of cost of treatment is one very much dependent upon the particular conditions existing, and upon the quantity that may require to be dealt with. The writer has personally dealt at one time with as large a quantity as 50,000 galls. per week, and found no difficulty in turning out an effluent free from iron or acidity. He would much prefer to advise definitely on any particular case submitted, but, generally, he estimates the cost of treating a quantity of waste hydrochloric acid amounting to not less than 20 tons (say, 3,600 galls.) weekly, at 3s. 4*d.* (three shillings and fourpence) per ton. He would estimate the cost of a suitable plant for this work, exclusive of any buildings, steam pressure, gas, water, or drains, all of which would probably be available without much extra cost, at 350*l.* 3s. If the quantity treated be greater, the cost per ton would be less, whilst the cost of the plant would not increase in anything like equal proportion to the quantity. As regards to smaller uses of hydrochloric acid, producing, say, 4 tons (720 galls.) weekly, the cost of treatment would be about 5s. 6*d.* (five shillings and sixpence) per ton, and the cost of a somewhat crude plant would be about 60*l.* In either of the above cases there would be a solid residue amounting to about 7½ cwt. for each ton of liquor treated.

36. No allowance seems to be made in this statement for carting away the sludge, which, as previously stated, in some instances would be a matter of no small cost.

37. Similar conclusions as to cost of treatment were arrived at by Mr. Jones, of Wolverhampton, in 1889.

38. Some idea of what such expense would mean to local manufacturers can be formed when it is stated that on the basis of Mr. Crosbie's figures, and from information in the writer's possession, it would cost one local manufacturer 728*l.*

per annum to treat his pickle, exclusive of first cost and wear and tear of plant, in addition to which 1,560 tons of sludge would have been carted away every year.

39. In connection with facilities for treating pickle, it may be stated that at the meeting held on the 25th July 1896, the following opinion was expressed, and was subsequently approved by the council, *viz.*:

"That a local authority should, as far as possible, afford facilities to manufacturers for dealing with pickle without polluting the rivers and watercourses, inasmuch as it is of importance that local trade should not be unnecessarily hampered.

40. Manufacturers as a rule are not only large rate-payers, but also large employers of labour; therefore there can be no doubt that local authorities should, while protecting the general interest of the inhabitants of their districts, afford such traders every facility for the development of local industries.

41. In the case of "*Peebles v. The Oswaldtwistle Urban District Council*," Mr. Justice Charles gave judgment to the effect that a local authority could be compelled, at the instance of a manufacturer, to make such sewers as are necessary for carrying off effluents from factories within their district. This decision was, however, reversed "on appeal," when it was decided that the proper remedy for any failure of duty on the part of the local authority would be by complaint, under section 299 of the Public Health Act, 1875, that the authority were in default in such respect. This "case" has since been taken to the House of Lords, whose decision is anxiously awaited.

42. Bearing in mind the present unsettled state of the law, and the advisability of the district authorities in the Stour Valley affording facilities for the development of local manufactures, it seems to me desirable that the authorities should offer the manufacturers terms for passing their pickle into their sewers. If the pickle be neutralised in the manner suggested, and stored in duplicate tanks until it could be discharged into the sewers by a duly authorised person, the local authorities could easily satisfy themselves that neither damage to sewers nor to sewage disposal works would result.

43. On the other hand, as it would be more costly, if not impossible, for some manufacturers in that locality to put down the plant necessary for effective neutralisation, in my opinion the district authorities should also take into consideration how far they can assist such manufacturers in their difficulty, and arrange for untreated pickle to be received into the sewers, provided of course that no objectionable gases were thereby evolved, and suitable payments for such accommodation were made.

44. Whereas in Wolverhampton the corporation took steps to prevent the local manufacturers from passing untreated pickle into their sewers, in Birmingham, where very large volumes of waste acid are produced, no such action is taken, and the only recognised damage to the sewers which has resulted has been that on two occasions some brickwork fell in.

45. It is not suggested that the discharges of the pickle should be haphazard, for the writer thinks it should be so controlled that rushes of acid may be prevented; and as to this there should not be much difficulty, for the time when pickle requires to be got rid of can be anticipated by the manufacturers, and consequently arranged for by the district officials.

46. In order to obviate difficulty as to sewage disposal, if such procedure were countenanced, the discharge of the pickle should be under the control of some duly authorised person, who should make arrangements for the pickle to reach the sewers when the volume of sewage is largest (in the morning, for instance), and in something like equal quantities from day to day.

47. Grouping of the various works for the purposes of pickle discharge would effect this latter desideratum.

48. Should the sewers in the Stour Valley district be damaged, the terms arranged between the manufacturers who care to make use of the sewers and the local authorities could be such that the ratepayers would not suffer.

### *Cowper-Coles Gold Recovery Process.* Engineer, 84, 1897, 273.

THE principal feature of the Cowper-Coles gold recovery process is an aluminium cathode, by which, it is said, one of the chief difficulties appertaining to the economical recovery of gold from weak cyanide solutions may be overcome, by electrolysis. In the Siemens Halske process lead foil or lead strips are used, the cutting up of which is a tedious matter. If several sheets are cut superimposed, the strips cling together, and have to be carefully spread out one by one, so that the surface may be exposed to the solution. A clean-up is made every seven to eight weeks, when the wood frames carrying the lead strips are withdrawn, the lead strips removed, and new substituted, the auriferous lead being ultimately melted down and conveyed to a central works to be cupelled. This method is both crude and expensive, the labour of fitting the strips into the frames is considerable, and the consumption of lead is a large item, having been computed by Mr. von Gernet, at the Worcester mine, at 1.10 of a penny per ton of ore treated. The Cowper-Coles process overcomes these difficulties, aluminium plates being substituted for the lead foil, advantage being taken of the fact that a loose oxide is formed on the surface of the aluminium, which enables the deposited gold to be readily stripped or wiped from the cathodes as pure gold. Gold by this process has been successfully extracted from cyanide solutions containing only 0.01 per cent. of cyanide of potassium,  $2\frac{1}{2}$  dwt. of gold to the ton of solution. The substitution of aluminium for lead foil, or strip, enables the gold to be obtained pure, and also daily returns to be made of the amount of gold recovered; it also has the additional advantage of reducing the cost of labour, and economising the amount of cyanide of potassium used, as the solution is not contaminated by any base metals, such as zinc, as in the other processes.

### *Roasting previous to Cyanide Treatment.* W. Macgregor, Eng. and Mining J. 1897, 64, [7], 187.

THE majority of ores are rendered more amenable to cyanide treatment, and in many cases with a smaller consumption of cyanide, by first roasting them. In this way, the cyanide solution is kept free from soluble salts than when raw ores are treated; a very high percentage of gold may be extracted from sulphide ores by the cyanide solution; a greater extraction of gold, with an equal or less consumption of cyanide, is obtained than with raw ore; low-grade silicious ores, carrying the gold in iron pyrites, are rendered amenable to cyanide treatment without previous concentration; and clayey ores lose their water of hydration and become porous, and the subsequent filtration becomes much more rapid. The most important condition for good extractions and low consumption of cyanide on a large scale is to have dead-roasted ore. Sulphide ores, after being only partially roasted, contain sulphates of iron, and these consume a large quantity of cyanide with formation of double salts. Sulphide ores, containing from 2—10 per cent. of pyrites, which will not give more than 20 per cent. extraction of gold in the raw state, will often give 85—98 per cent. after a dead roast and treatment with cyanide. Mixed oxidised and sulphide ores often have an acid reaction, but on roasting, the acidity is destroyed, and the gold in the sulphide ores is rendered more amenable to the action of the cyanide, whilst a higher percentage of gold from the part that was originally oxidised, is frequently saved; the destruction of the acid quality of the ores does away with subsequent lime or soda-ash treatment, which causes trouble in percolation and in the zinc boxes. Very low grade ores and tailings do not pay for roasting, and there are some heavy sulphuretted ores and concentrates where roasting interferes with the extraction of the gold, and causes a very heavy consumption of cyanide. The advisability of previous roasting should be carefully determined in each case, both by laboratory experiments and by small plant tests. The following method is suggested for determining whether the ore is "dead-roasted."—100—250 grms. of the roasted ore are taken from the discharge end of the furnace; the ore is cooled, shaken in a beaker with about 200 c.c. of water, filtered, and to the filtrate is slowly added a small quantity of cyanide solution made up

to the same strength as that used in the regular work of the plant. If no cloudiness at all appear, the ore is dead-roasted, or at least well fitted for treatment by cyanide solution, and the consumption of cyanide will be normal. If a brown coloration be formed, there are some soluble salts of iron left in the ore, which will cause a greater consumption of cyanide, and may lead to a precipitation of compounds of ferrocyanide in the zinc boxes. If there is formed a blue colour changing to a greenish-blue precipitate, the ore is very badly roasted, and there will be a high consumption of cyanide, and the circulating solution will be made foul.—A. S.

*Cyanide Process [Gold]; Sump Solutions, Extractor-Box Work, and Cleaning up in; Notes on.* A. James. Inst. Mining and Met., 1897, 8 pp.

EXPERIMENTS were made to test the relative gold-extraction efficiency of fresh and of used cyanide solutions, in which foreign matter had gradually accumulated. It was found invariably that the sump (or old) solution was inferior, giving an extraction of 90 to 95 per cent. of that obtained with the fresh cyanide, with ores ranging from 4 oz. to 21 oz. per ton. The use of lime brought the efficiency up to the normal with pure quartz ores or tailings, but not with those containing any appreciable proportion of sulphides. The addition of sodium sulphide, followed by an excess of a soluble lead salt (acetate or chloride), was successfully tried, time being given for the subsidence of any precipitated sulphides. In this way, the necessity of running foul sump solutions to waste may be avoided when water is scarce, or the cyanide or gold contents are high. It has been thought by some that, in practice, the double cyanide of zinc in the presence of potassium hydroxide would break up into  $K_2Cy$ ,  $K_2ZnO_2$ , and water; but in reality the reverse takes place, with the result that, when free zinc oxide is present, some of the cyanide added to bring up the solution to the working strength is taken up, without any indication of this being given by the silver test, so that the solution becomes less effective for the solution of gold than the cyanide alone would have been. This is a point in favour of the electrical deposition process, for which, however, insoluble anodes are much needed. Accumulations of zinc in the solutions from the old process may be avoided by the use of sodium sulphide solution, as above described.

*Losses in Cleaning up.*—The methods adopted vary greatly, and it was hoped that it would be possible to find out the causes of loss in each case, and to discover the best method of working. By shaking the gold slimes off the zinc, drying and mixing well, it was found that the losses varied from 0.5 to 6 per cent.; the less the handling of the slimes, the less commonly being the loss. The heaviest losses were incurred in roasting (in proportion to the stirring and handling), the least loss observed on this account being 0.23 per cent. in addition to those resulting from the rest of the treatment. With the nitre method of roasting (this Journal, 1897, 3), the loss was 2.57, which might, however, be reduced with practice. With acid treatment, the loss varied with the nature of the acid, nitric acid causing a greater loss than sulphuric or hydrochloric acid. With the ordinary impure zinc, however, the resulting bullion was purest when nitric acid was employed. With zinc free from lead, the best bullion and the least loss followed the use of sulphuric acid. When the slimes had been passed through a 40-mesh sieve, the bullion obtained by direct melting was fairly pure, and the results were as good as with acid treatment; whilst with scrap and coarse zinc included, the latter method was more advantageous. The lowest total loss obtained was 0.75 per cent., and this was with the sulphuric acid treatment prior to melting. One experiment with lead-free zinc gave a total loss of 0.52 by direct fusion of the sieved slimes, the coarse zinc being treated with sulphuric acid, and the residue being added to the slimes. Pure zinc always gave a loss (averaging) 0.2 per cent. less than that observed with ordinary zinc. Treatment of the slimes with strong solutions of alkali or cyanide (with or without acid treatment subsequently) gave higher losses. Considering the loss in simple melting with borax as  $x$ , it was found that the losses were as follows:—

	Per Cent.
Roasting, followed by melting.....	$x + 0.23$
Sulphuric acid, followed by melting.....	$x + 0.17$
Sulphuric acid, roasting, then melting.....	$x + 0.40$
Nitric acid, followed by melting.....	$x + 0.29$

With pure lead-free zinc,  $x$  was 0.43 per cent.; with ordinary zinc it exceeded 0.63. With the former, the roasted bullion was more base than that melted direct with borax. With ordinary zinc the reverse was the case, while the loss by acid treatment was greater, and that by roasting less, than with lead-free zinc. Possibly, the presence of lead, producing fluid lead oxide during roasting, may account for this smaller loss.

From these experiments, it is suggested that roasting be avoided, that the material should be handled as little as possible, and that the number of vessels should be limited. The zinc boxes should discharge their slimes by steel launders through a 40-mesh into small steel vessels with perforated bottoms covered with a filter-cloth. Each of these vessels fits into a small vat, and is so arranged that the overflow of the slimes passes into a large vat, which, with the aid of a filter with a vacuum receiver, collects all the overflowed light slimes from the steel vessels. The slimes are then at once sent to the drying and mixing plate; or the cake of slimes from the steel vessel is emptied into the acid vat, which may be of lead-lined wood, of specially varnished steel, or of aluminium, the latter not being attacked by sulphuric or even nitric acid. The slimes, after acid treatment, are washed with hot water and filter-pressed, run into a detachable steel-lined filter vat with vacuum connection, washed, vacuum-dried, fluxed, and melted. The latter process is preferred to filter-pressing, as being cleaner, simpler, and less liable to cause loss.

*Purity of Gold Bullion.*—At first it was thought that the lead was necessary to cause the precipitation of the gold with sufficient energy, but it is now found that the presence of a minute amount of iron is enough to produce the desired effect. By adopting a special lead-free zinc for this purpose a purer bullion is obtained; the refiners' fine, ranging from 3*d.* to 1*s.* 8*d.* (and averaging 9*d.*) per oz. of fine gold when lead is present in the bullion, may thus be obviated, whilst the bulk of slimes to be treated will be less, and the loss as above during clean-up will also be reduced by 0.2 per cent. On the other hand, the cost of the zinc will be higher; but, remembering that about 1 lb. of zinc is consumed per oz. of fine gold, there may be a difference of 11*d.* in the prices of the two varieties of zinc, with still a margin in favour of the better quality.—W. G. M.

*Gold, Solution of, in Accumulated and Other Slimes.*  
W. A. Caldecott. Proc. Chem. and Metall. Soc. of S. Africa, July 17, 1897, 18—22.

Pyritous ores which have been settled in dams or pits are liable to contain ferrous sulphide, and this imparts a grey or black colour to the material, 0.25 per cent. of  $FeS$  being often found in the more pyritous layers, with practically no ferrous salts or free acids. This and ferrous oxide both absorb the free oxygen from the solutions, and it is necessary either to pump in air or to use an oxidising agent,  $\frac{1}{2}$  to  $\frac{1}{3}$  lb. of potassium permanganate per ton of dry slimes being a suitable addition. All plants now under construction for the treatment of accumulated slimes will be equipped with air-compressors capable of delivering 1,800 cb. ft. of air per min. Under these conditions the vats should be deep and the bubbles of air as small as possible, in order to secure the maximum aëration; it is also advisable to supply the air as rapidly as possible, because a given volume of it is required for any given proportion of deoxidising agent, independently of the time occupied in applying it. The addition of the lime to old and acid slimes, precipitates ferrous oxide, which absorbs oxygen and adds to the necessity for preliminary aëration. By such treatment the consumption of cyanide has been reduced by one-half (to  $\frac{1}{2}$  lb. of  $KCy$  per ton of dry slimes). The aëration is effected by means of perforated pipes at the bottom of the tanks, and lasts (with agitation) for from 2 to 20 hours, according to the proportion of ferrous sulphide. After complete oxidation of sulphides, the treat-

ment is continued for two hours, the cyanide solution is added, and aeration proceeds again for from 2 to 5 hours. Lime is added during the charging and preliminary aeration, in sufficient quantity to yield an alkali strength of liquid corresponding to from 0.006 to 0.01 per cent.

In the laboratory, the percentage of dry slimes, or the ratio of slimes to solution, in any pulp may be determined with fair accuracy from its sp. gr.  $x$ , by applying the following formulae:—

$$\text{Percentage of dry slimes in pulp} = \frac{158.8(x-1)}{x}$$

$$\text{Slimes : Solution} = (x-1) : (1-0.37x).$$

All tests to determine gold extraction must be made on the moist material, as the process of drying, causes an oxidation of the reducing substances present. Alkali tests are made by Clennell's method:—100 c.c. of solution are taken, the cyanide strength is determined by standard silver nitrate solution (1 c.c. of  $\text{AgNO}_3$  sol. = 0.01 per cent. of  $\text{KCN}$ ), one or two excess drops of  $\text{AgNO}_3$  solution are then added, a few drops of a 0.5 per cent. solution of phenolphthalein are added, and the titration is effected with decinormal sulphuric or oxalic acid.—W. G. M.

*Bullion, Low-grade : Plant for Parting.* F. Gutzkow, Eng. and Min. J. 1897, 218.

Two flat-bottomed cast-iron pans 4 ft. square are used, one of which is 2 ft., the other only 15 in. deep; the larger kettle is mounted over a fireplace, whilst the smaller is heated by the waste heat from the other. Both are covered with wooden chambers provided with vertically sliding doors, the former being lead-lined and having a leaden flue with a good draught. The pans might be round-bottomed, but square and flat bottoms are more economical of space and are more easily manipulated. The bullion is cast in slabs 12 in. square with 2-in. holes in them; 20 or more of these are suspended by S-shaped iron hooks from lead-sheathed iron rods, which rest on a lead-covered iron frame 3 ft. square, supported by four vertical iron rods (also enclosed in leaden pipes) from the roof of the chamber. These are secured by screws to a wooden frame resting upon the roof. The whole arrangement can be lifted by means of a windlass on the floor of the room. The acid is not allowed to touch the lead-covered iron rods; the suspending hooks dissolve rapidly, but are not costly to replace.

In this apparatus about 800 lb. of low-grade bullion (containing 25 per cent. of Ag and 75 per cent. of Cu) may be treated every 24 hours in about 20 slabs weighing from 40 to 50 lb. each. About 2,000 lb. of strong sulphuric acid will be consumed in the operation, but 6,000 lb. will be required in all, 2,000 lb. being placed in each pan, and the remainder in a sheet-iron reservoir (afterwards used as a crystallising pan), where it is diluted to 60° B. and forms the mother-liquor for the crystallisation of the copper sulphate. As the bullion dissolves in the first pan under the action of heat, the acid consumed, is replaced by the diluted acid from the reservoir, in order that the concentration of the liquid may not cause the crystallisation of the copper sulphate. After three hours, 100 lb. of the bullion should be dissolved, and one-eighth of the diluted acid should have been spent; the frame with the suspended plates is then raised sufficiently to allow of the deposited powder of copper sulphate crystals (about 1 cb. ft. in bulk) being raked to the corners nearest the second pan. A slide, which forms part of the partition between the two pans, is raised, and the powder is raked into the second pan. The partition is then lowered again, diluted acid is introduced, and the operation is continued for another period of three hours, and so on, until after eight of such periods the parting should be complete. The copper sulphate in the second pan is stirred in with the strong sulphuric acid, in order to free it from silver sulphate, and is then taken out for further treatment. The silver is ultimately concentrated in the first solution, which is then siphoned into the crystallising pan (provided with a lead-lined flue for the fume), and the first pan, being left empty, is filled up with acid siphoned from the second pan. When all fume from the first pan has ceased, the sliding doors are opened, pieces of sheet-iron are placed on the pan, the remnants of the bullion are removed, and the frame is charged with a new batch of bullion for a fresh

run. The crystallising pan, which is still being used to work off the first batch, would then be required; it is therefore advisable to have two of these latter pans, which may be used alternately. Scraps of bullion too small to be suspended again are remelted. The hot silver solution in the crystallising pan is cooled by means of a jet of steam until it may be safely diluted down to 60° B. by means of about 500 lb. of water added in a small stream. The mixture is then allowed to cool, and the silver sulphate is gradually crystallised out in the ordinary way.—W. G. M.

## PATENTS.

*Ferro-Sodium Fluxes, Impts. in; more particularly those adapted for use in the Manufacture of Iron and Steel.* A. E. Tucker and T. V. Hughes, both of Birmingham. Eng. Pat. 14,222, June 26, 1896.

Oxide of iron, dry sodium carbonate, and dry powdered carbon, generally in the respective proportions of 100, 100, and 44 parts, are finely powdered, mixed, and made into blocks with a suitable binding material, such as 5 per cent. of tar. The blocks are dried at a low temperature and then heated sufficiently to reduce the oxides, but not to vaporise the sodium. The blocks of ferro-sodium so obtained are cooled, coated with paraffin wax to preserve them from the air, and are used chiefly to add to the bath of molten iron, after blowing, to remove the oxides therefrom.—A. W.

*Metals, Impts. in and connected with the Alloying of.* A. E. Tucker and T. V. Hughes, both of Birmingham. Eng. Pat. 14,223, June 26, 1896.

To prepare the alloying metal in a convenient form for admixture with the mother-metal, the oxide is mixed with carbon, and the two are ground together and made into blocks with tar or other binding material. These are slowly dried, and then heated until the oxide is reduced. The blocks of metal so obtained are protected from the air by coating with wax, and are added, when convenient, to the molten bath.—A. W.

*Gold Separating from other Materials, Impts. in Apparatus for.* W. H. Hyatt, Herne Hill. Eng. Pat. 16,932, July 20, 1896.

This invention relates to improvements in detail in the apparatus described in specification, Eng. Pat. 24,782 of 1894; this Journal, 1896, 119.—J. H. C.

*Metals [Gold, Copper], Improved Process for Extracting.* W. P. Thompson, Liverpool. From A. Sinding-Larsen, Christiania, Norway. Eng. Pat. 22,355, Oct. 8, 1896.

To extract the metals from ores containing sulphur, the raw material is pulverised, washed if necessary, and exposed to and agitated in a current of chlorine, or other halogen gas, free from air. If the subsequent treatment is dry the ore is heated while the chlorine is passing, and the volatile chlorides are passed into a series of receivers heated to temperatures corresponding to the condensation points of the various chlorides, so that the latter become separated one from the other. The chlorides are then dissolved separately in water and electrolysed. By the wet process the chlorinated ore is leached with water, the solution electrolysed, and the chlorine recovered for further use. Metallic iron is used to precipitate the copper, if present in quantity, and the iron chloride solution so obtained is again electrolysed to recover the chlorine.—A. W.

*Gold and other Precious Metals, Impts. in and relating to the Recovery of.* T. G. Bowick, London. Eng. Pat. 15,569, June 30, 1897.

In preference to running the ore, pulp, or slime containing the gold over stationary surfaces, it is carried over a series

of revolving cylinders, tables, or endless bands, so as to avoid the friction between the ore and the amalgamated plates. The surfaces of the cylinders, &c., consist, preferably, of amalgamated copper, and may be connected, if necessary, with the poles of an electric battery.—A. W.

*Copper, Metallic; Elimination of Arsenic from, Impts. in connection with.* B. Thomas and J. W. Thomas, both of Llanelly. Eng. Pat. 17,941, Aug. 13, 1896.

THE copper is melted in a reverberatory furnace, and is there subjected to the conjoint action of fluxes and air. For the former, soda ash is preferred as being cheap and effective, but sodium nitrate or a good black oxide of copper may be employed. About 1 to 1½ cwt. of flux is commonly required for a charge of 10 to 12 tons of copper. The air is introduced at a pressure of 35 lb. to 40 lb. per sq. in. by means of (¾ to 1 in.) iron piping protected by a silicious coat, and is delivered 3 or 4 ins. below the surface of the metal. The slag fuses and is removed from time to time; it contains 0·8–1 per cent. of Cu, which may be reduced to 0·25 per cent. by introducing it into the ore-smelting furnace. In some cases the copper may be removed from it by direct carbon-reduction. A special mixing machine is also described, by which the fluxes may be conveyed regularly by a screw into a hopper, through which they are carried on by and with the compressed air, and thus passed through the metal itself. By this process the arsenic in 10 or 14 tons of copper may be reduced from 1·25 to a mere trace in 12 hours. The copper may easily be brought up to 99·5 or 99·75 per cent., and even in the presence of bismuth the metal is tougher after treatment.

—W. G. M.

*Aluminium Alloys, Impts. in the Means for and Method of producing certain kinds of Metal (especially adapted for use in the Manufacture of the Tubes and other of the Component Parts of Cycles of all kinds, Autocars, and other Wheeled Vehicles, which Improvements are also applicable for other Industrial Purposes.* W. Van Wart, F. W. Popp, and J. J. Bradley, Birmingham. Eng. Pat. 19,640, Sept. 5, 1896.

THE mixture generally used consists of aluminium about 100 parts, copper 1 to 10, zinc ¼ to 6, tin ½ to 4, silver ¼ to 6, phosphorus ⅓ to 1. Sometimes the copper is omitted, from ½ to 4 of regulus of antimony being substituted. In the first case the copper is all melted, then the zinc and silver are added, then the aluminium, and finally the tin and phosphorus. In the second case the silver is melted first, then the aluminium is added gradually, then the zinc and regulus of antimony, and finally the tin and phosphorus.

—J. H. C.

*Steel or Iron, Annealing of; Impts. relating to the.* D. C. Dalzell, Handsworth, and A. Fairley, Birmingham. Eng. Pat. 22,976, Oct. 19, 1896.

IN the annealing of ("malleable") castings of iron or steel, the objects are coated over with a wash of red hematite ore, or with clay or lime, prior to placing them in the furnace, and the usual packing in hematite may then be dispensed with.—W. G. M.

*Toughening or Strengthening of Metal, Impts. in or relating to the; particularly applicable to Steel Tubes and Brazed Joints.* R. S. Lovelace, Henstridge, Somersetshire. Eng. Pat. 21,175, Sept. 24, 1896.

THE hot metal is quenched in a mixture of linseed oil, borax, soda, and india-rubber.—E. H. L.

*Blast Furnaces, Iron; Impts. in the Method of Working, so as to utilise the Gases evolved for producing Motive Power.* B. H. Thwaite and F. L. Gardner, both of London. Eng. Pat. 23,597, Oct. 23, 1896.

THIS is an extension of the principle of Eng. Pat. 15,684 of 1896. The gases from blast-furnaces may be utilised even at times when the furnace would ordinarily be shut down, by running it on fuel, sand, and limestone, whereby a vitreous material or slag would be produced (and no iron), and the plant depending upon the gas for its motive power would not be caused to stand idle. The value of the gas

is indicated by burning a small quantity in a motor and testing with a speed-indicator. The hot gases are passed through a number of tubes, to cool them before purification, and their heat may thus be given up for the warming of the air for cold-blast furnaces. The air for hot-blast furnaces may be heated by alternating stoves; but instead of using the furnace gases for this purpose, it is preferable to employ the latter as motive power, and to burn a cheaper fuel to operate the stoves. In this case, if the blast furnaces should from some cause cease to work, a gas supply may still be obtained by employing that from the coarser fuel.

—W. G. M.

*Alloys (Iron) [Non-Magnetic], Impts. in the Manufacture of.* R. A. Hadfield, Sheffield. Eng. Pat. 24,703, Nov. 4, 1896.

ALLOYS suitable for dynamo brackets, or for similar purposes, are made by melting together iron and carbon (commonly about 3½ per cent.) with other materials, to give a composition of 7–30 per cent. of Mn, and either 2½–8 per cent. of Si, or 2–8 per cent. of Al, or 1½–8 per cent. each of aluminium and silicon. Appropriate alloys may be made from No. 1 hematite pig, silicious pig, ferro-manganese, and aluminium to yield, e.g., 3½ per cent. of C, 13 per cent. of Mn, and 6 per cent. of Si; 3½ per cent. of C, 13 per cent. of Mn, and 4½ per cent. of Al; or 3½ per cent. of C, 13 per cent. of Mn, 6 per cent. of Si, and 2 per cent. of Al. The metals may be melted together, or they may be melted separately and then mixed. The more manganese added, the less magnetic will be the alloy, but the more difficult it will be to change the carbon from the combined into the graphitic form, as is necessary.—W. G. M.

*Steel, Manufacture of, by the Bessemer or Open-Hearth Process; Impts. in.* C. H. Foote, W. R. Walker, E. A. S. Clarke, all of Chicago, U.S.A. Eng. Pat. 8763, April 6, 1897.

THIS process relates mainly to the making of the final additions of carbon and manganese to the decarburised steel. The manganese is added direct from the spiegel blast furnace without remelting in cupolas. Two small smelting furnaces are employed, the duplication being provided as a safeguard against a breakdown of any part of the furnace. The spiegel may thus be made of any required grade, and should be conveyed from the furnace to the steel plant in a ladle sufficiently large to hold one or more casts of the furnace, and thus to serve as a mixer; or it may be carried in small ladles to a mixer. It is then tapped from the ladle or mixer in suitable quantities for use. The spiegel in the mixer is diluted with pig-iron, or is mixed with irons of such compositions that material having exactly the required analysis may be used in the steel-bath. In this way the nature of the spiegel is under perfect control, and may be altered at a moment's notice. But as the smelting of high-grade spiegel is expensive, owing to the costly nature of the ores to be used, it is recommended that a metal be prepared with 8–12 per cent. of Mn in the miniature furnace, by using cheap low manganese ores, and that it be brought up to the required percentage by the addition of ferro-manganese to the metal in the mixer, either in the molten condition or (preferably) in pieces the size of a hickory nut, which have been heated to a red heat. These fragments are best added in the runner leading to the mixer, so that a thorough incorporation may be effected. The ladle used for conveying the spiegel from the furnace should be provided with an oil or a gas-burner, or the metal should be covered with charcoal or coke dust, to retain the heat; and after the addition of the higher-grade ferro-manganese, a bar of wood should be introduced into the bath to ensure thorough incorporation of the whole.

—W. G. M.

*Metals (Copper, Iron, &c.), Impts. in or relating to Uniting or Welding.* J. Andrews, Allegheny, U.S.A. Eng. Pat. 8780, April 6, 1897.

A PROCESS for uniting copper or alloys thereof, to other metals, such as iron in plates, &c. The iron is first coated with a film of copper by cleaning and placing it in an acid solution of sulphate of copper, and is then clamped to the plate of copper to which it is to be welded. The whole is

heated, and the iron and copper plates, with the deposited copper between them, are united by pressure or by passing through rolls.—A. W.

*Melting and Casting Metal, Impts. in or relating to Apparatus for use in.* L. Rousseau, Paris. Eng. Pat. 9421, April 13, 1897. (Under Internat. Convention.)

THESE improvements have chiefly for their object a perfect combustion of gases from the fuel and utilisation of the heat produced; the air is admitted as much as possible in a direction opposite to that in which the gases travel.

—J. H. C.

*Composite Metal Plates, Impts. in the Manufacture of.* H. Wachwitz, Nuremberg. Eng. Pat. 11,550, June 16, 1897.

THIN sheets of copper (about 0.1 mm.) are laid on aluminium sheets (of about 10 mm.), and heated between red hot plates, and then rolled or pressed. The composite sheets thus produced, can be worked like sheet copper, brazed, tinned, or galvanised.—J. H. C.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A.)—ELECTRO-CHEMISTRY.

*Colloids, Electric Migration of.* Coehn. Zeits. für Elektrochem. 1897, 4, 63—66.

IN a former research, the author drew the conclusion from the fact that a coloured fluid followed the direction of the current during electrolysis, that coloured ions existed. A substance free to move, will move in or against the direction of the current if it be electrically charged. This is the case with the ions during electrolysis, as shown by a lecture experiment of Nernst's, in which the  $MnO_4$  ions, during electrolysis of potassium permanganate, move towards the anode; it is also true of fine suspended solid particles in water or in turpentine, their static charges carrying them towards the oppositely charged electrode, while the liquid particles move towards the other one.

The author and Euler have found that colloids—caramel, starch, and tannin—non-electrolytes, behave in a manner exactly similar to such solid particles, moving in water towards the anode; this fact has already been noticed in the case of tannin, and is the foundation of the process of electrical tanning.

Colloids in which electrolytic dissociation might possibly take place—ferrie hydroxide, for example—have also been investigated. Dialysed ferrie hydroxide had the last traces of chlorine removed from it by electrolysis with a silver anode, and was then submitted to the current between two layers of water. A dark layer moved from the anode, while a more rapid movement of a lighter-coloured layer took place towards the cathode. This layer would not pass a parchment membrane, and hence could not contain iron ions. The different behaviour of these electrolysable colloids from the others is being further investigated.—J. T. D.

### PATENTS.

*Acid-Proof, Electrical Non-conducting Articles, and Composition therefor: Impts. in.* W. Morrison, Montclair, New Jersey, U.S.A. Eng. Pat. 18,485, Aug. 20, 1896.

THIS composition for a new non-conducting acid-proof and acid-tight battery case, consists of asphaltum, gutta-percha, asbestos, and sulphur mixed and beaten together at a temperature of about 60° C. It can be readily moulded, and, possessing a polished surface, does not require any further treatment.—F. H. L.

*Secondary Battery [Lead] Plates, Impts. in Active Material for.* The Sussmann Electric Miners' Lamp Co., Ltd., and S. A. Rosenthal, London. Eng. Pat. 21,749, Oct. 1, 1896.

"ACTIVE material, for application to a lead conductor to form a secondary battery plate, consisting of a finely powdered lead oxide made into a stiff paste by intimate

mixture with a thin india-rubber solution, sulphate of ammonium solution, and, if desired, powdered inert material [asbestos, slag wool] . . ."—J. C. R.

*Electric Currents, Controlling the Direction of Flow of, or Retarding such Flow, and for like Purposes; An Improved Cell for.* [Aluminium Anodes.] W. P. Thompson, London. From Dr. Leo Gratz, Munich, Germany. Eng. Pat. 23,084, Oct. 17, 1896.

THIS invention has for its object a cell for controlling the direction of flow of electric currents, or retarding such flow, and for like purposes, and is based on the property possessed by an aluminium anode of strongly diminishing the flow of current in an electrolyte, which separates oxygen at the anode directly, or by means of secondary processes.

"This property of aluminium has been attributed to the formation of a very bad conducting layer on the anode, that is to say, of a resistance; but the correct explanation should be sought in the production of a kind of polarisation of very considerable extent, or of a condenser action; and measurements undertaken for this object have shown that the counter force resulting thereby amounts to 22—25 volts."

Claims: (1) "Cells having different resistances for the two directions of current flowing through them (choking cells), consisting of an electrode of aluminium or aluminium alloy arranged in an electrolyte which separates oxygen at the aluminium as anode, directly or by secondary processes (for example, alum solutions, alkali sulphate, alkali nitrate, caustic alkali solutions, acids), in connection with either (a) another electrode of carbon or any suitable base or noble metal (with the exception of platinum), or of a metal alloy that is not soluble by chemical action in the liquid used; or (b) any desired electrode in an electrolyte (acids, salts solution) which is divided from the former by a diaphragm . . ." Other (four) claims relate to applications of these "choking cells" for electrical purposes.

—J. C. R.

*Batteries, Electric Primary and Secondary; Impts. in.* V. Jeanty, Paris. Eng. Pat. 12,827, May 24, 1897. (Under Internat. Convention (France), Nov. 19, 1896.)

THE object is to separate the "depolarising liquid" from the "exciting liquid" without employing porous partitions. The electrodes are arranged horizontally in troughs, with the depolarising solution or oxide occupying the lower position.

Claims: (1) "In electrical batteries (primary or secondary) the provision of separate impervious baths of either circular or rectangular shape, arranged horizontally, and adapted to contain depolarising or any other suitable liquid, as well as one of the electrodes . . ."—J. C. R.

*Electric Accumulators [Lead: Active Material], Impts. in and relating to.* I. Celestre, Syracuse, Italy. Eng. Pat. 26,491, Nov. 23, 1896.

(1) "THE process of preparing active material for accumulator plates by means of simply sulphatug oxides of lead . . . and with the complete exclusion of all foreign substances, whether as an adhesive material or as a reacting material." ["Oxides of lead, either alone or mixed with electrolytic lead, are treated with a solution of sulphuric acid; the mass is then worked into a paste with carbonate or sulphate of lead, the quantity of the latter ingredient varying according to the degree of porosity which the mass is desired to possess . . ."] (2) "The use of carbonate or sulphate of lead in the preparation of this material, by means of which there may be obtained the degree of porosity desired." (3) "Frames for accumulator plates provided with curves of dilatation [so that the dilatation of the active material can take place without any hindrance] . . ."—J. C. R.

*Wood and other Cellular or Fibrous Substances, Improved [Electro-Capillary] Process and Apparatus for Treating or Saturating with Liquids.* L. A. Bretonneau and

A. L. C. Nodon, Paris, France. Eng. Pat. 13,242, May 28, 1897.

THE apparatus consists of a vat of brickwork cemented internally, the lower portion of which contains the anode and the solution with which it is desired to impregnate the wood or other substance. The wood, which only dips to a depth of a few centimetres into the liquid, rests on a support of felt or other porous material, which covers a perforated lead anode supported by a wooden floor resting on blocks. The bottom of the tank is sloped and provided with an opening through which it may be emptied. A porous partition covers the wood and ensures contact between it and a porous vessel resting on it, filled with pure water, and on the bottom of which is the cathode, which is preferably an iron plate. This vessel is supplied with water, which is constantly withdrawn by means of a siphon. The current density employed should not exceed one-third of an ampère for every square decimetre of material treated.

—G. H. R.

*Primary Batteries or Cells [Amalgams], Impts. in.* I. Kit-ée, Philadelphia, U.S.A. Eng. Pat. 14,508, June 15, 1897.

RELATES to the construction of a battery having as electrodes an alloy of mercury and a metal, as zinc, a metallic rod surrounded with "a high oxide of lead," and dilute sulphuric acid as electrolyte. Both electrodes are surrounded or enveloped by some inert porous material or cups, as wood or plaster of Paris.—J. C. R.

*Electric Batteries [Manganese], Impts. in.* L. W. Pullen, Camden, New Jersey, U.S.A. Eng. Pat. 16,969, July 6, 1897.

AN "electric battery having the cathode arranged in a depolarising mass, consisting of finely divided carbon [plumbago, coke], a salt of manganese [sulphate], and concentrated sulphuric acid uniformly distributed throughout said mixture."—J. C. R.

*Electric Accumulators [Lead], Impts. in or relating to the Electrodes of.* E. W. Jungner, Stockholm, Sweden. Eng. Pat. 16,362, July 10, 1897.

"IN positive electrodes of electric accumulators, in which the active support consists of metallic lead or lead alloy, and the electrolyte of a suitable acid, the method of covering the surface of the metal, by mechanical, chemical, or electrical means, with a conducting compact coating of peroxide of lead, between the molecules of which a suitable material ['paraffin'] is introduced for the purpose of binding the same together . . ."—J. C. R.

*New Galvanic Element [Zinc-Carbon].* C. D. Abel, London. From C. N. Sehnoff, St. Petersburg. Eng. Pat. 17,026, July 19, 1897.

(1) "A GALVANIC element with 'circulating depolarisation,' characterised by a depolarising mass, which is composed in such a manner that the oxygen of the depolariser becomes continuously regenerated by the production of exchange operations . . ." (2) "In the element specified in the first claim, the use of a diaphragm, which is only permeable to water and gases . . ."—J. C. R.

### (B).—ELECTRO-METALLURGY.

*Slimes, Battery; Treatment of.* J. R. Williams. Trans. Chem. and Metall. Soc. of S. Africa, July 17, 1897, 14—18.

THE first slimes-plant to be operated (that of the Crown Reef Gold Mining Co.) has been in use for 12 months, and, after several small troubles, is working successfully, having paid its way from the very first. The slimes may be passed through a large sand separator, but this is rarely required, as the proportion of sand leaving the tailings plant is negligible; the liquid then runs through a launder, in which milk of lime is added to precipitate the slimes (in a flocculent form). The lime must be neither in excess or in insufficient quantity; and the introduction of an automatic

lime feeder, invented by Seymour, has effected a saving at the rate of 1,200*l.* per annum in lime alone. The mixture passes through two settling pits, each 20 ft. by 20 ft., by 10 ft. deep, in which 80 to 90 per cent. of the slimes deposit, the overflow passing to another tank 40 ft. by 40 ft. by 10 ft., the effluent from which is practically clear. These pits come down to a point, forming an inverted pyramid, and are each connected with a centrifugal suction pump, which delivers the settled slimes into eight tanks for treatment, together with about 10 per cent. of the water originally contained in them, which cannot thus be separated. These tanks are 32 ft. in diameter, and 10 ft. deep, with conical bottoms, and are arranged in series of four. The first receives the sludge, which is allowed to settle in it, and the effluent is then drawn off. The sludge is then pumped into the second tank, a jet of cyanide solution being used to sluice it into the suction of the centrifugal pump, and the tank is then filled up with cyanide, the strength of the whole being made up to 0.01 per cent. of KCy. It is found that 80 per cent. of the gold is dissolved in passing thus through the pump; nevertheless the mixture is agitated by a circulation pump for two hours, and is then allowed to settle, and the solution is drawn off through a series of side-cocks (to which siphon pipes are preferable). The settled slimes are then pumped into a third tank, where they are agitated with a very weak solution of cyanide and allowed to settle, the resulting solution being used for the first treatment when transferring from the first to the second tanks. Then the residual slimes are finally pumped, together with still more dilute cyanide liquor, into the fourth tank, the liquid from this being used in transferring the material from the second to the third tank. The comparatively clear solution from the second tank is run into settling tanks 15 ft. in diameter and 5 ft. deep, and when perfectly clear is passed through the electrolytic precipitation boxes from below upwards. These boxes are 30 ft. long by 6 ft. wide by 4 ft. 9 ins. deep, and have iron and lead anodes; the effluent is used over again. In using this plant the gold tends to concentrate in the liquor, so that the solution passed to the precipitating vats assays 60 grs. The cost of treatment per ton is 3*s.* 9'<sup>05</sup>/<sub>d.</sub>, which is made up as follows:—

	d.
Management and European wages.....	9'44
Kaffirs and food.....	3'20
Electric light.....	0'40
Power.....	2'75
Cyanide.....	5'51
Lime.....	6'19
Lead foil.....	1'75
Oil and waste.....	0'89
Assaying.....	1'26
Sundries.....	0'63
Royalty.....	4'77
Maintenance (labour, 4'13 <i>d.</i> ; stores, 3'17 <i>d.</i> ).....	8'17

This estimate is based on two months' working (April and May), during which 6,640 tons were treated, with an assay value of 5.32 dwt., yielding 1,067 oz. of gold, with an actual extraction of 60.48 per cent., and giving a profit of 3,058*l.*

In regard to rate of precipitation by electrolysis, the result of an experiment by Butters, with a solution containing 2 dwt. 12 grs. of Au per ton, showed that the liquid, after successive periods of treatment of three hours each, assayed 1 dwt. 4 grs., 20, 12, 8, 4, 2, and 0.5 gr.; whilst after 24 hours only a trace of gold was left.—W. G. M.

*Nickel, The Electrolytic Separation of, from Solutions of the Sulphates and Chlorides.* F. Foerster. Zeits. f. Elektrochem. 4, 160—165.

THE author describes experiments undertaken in order to judge of the possibilities of the successful production of nickel, by electrolytic methods upon an industrial scale of operation.

*Electrolysis with Soluble Nickel Anodes.*—This is the method used in electro-plating with nickel, but only very thin coatings of nickel have been obtained.

If the electrolysis be continued, the deposit becomes scaly in character, and small lamellæ break away from the surface of the electrode and curl up.

The author has found that this difficulty can be overcome by use of a hot electrolyte. At temperatures ranging from 50° to 90° C., tough deposits of nickel of any desired thickness may be obtained from either the sulphate or the chloride salt solution. The former is, however, to be preferred. The solution used contained 145 grms. of commercial nickel sulphate per litre. A thick plate of nickel was used as anode, and a thinner sheet of nickel as cathode. The nickel used contained from 1.5 to 2.0 per cent. of impurities, chiefly iron and cobalt, with smaller amounts of carbon, silicon, copper, and manganese. The anode was covered with parchment paper in order to maintain a clear electrolyte. This parchment covering was not attacked in the hot sulphate solution; but in the chloride solution it quickly rotted, and was dispensed with altogether in later experiments. Circulation of the electrolyte was maintained during the deposition, and apparatus was used to supply the deficiency in water or acid caused by the evaporation at the high temperatures used. Current densities are all expressed in ampères per sq. decimetre. (1 ampère per sq. decimetre = 9.21 ampères per sq. foot.) Using the nickel sulphate solution of the concentration named at temperatures of from 50° to 90° C., and current densities varying from 0.50 to 2.5 ampères, satisfactory and bright deposits of a light grey or tin-white colour were obtained. The deposits increased in lightness of colour and in smoothness, with increasing current density.

From a more concentrated solution of nickel sulphate (= 100 grms. nickel per litre) a current of 0.50 ampère density deposited the metal in a dull and rough state, whilst from the same solution a current of between 2 and 2.5 ampères in density yielded the metal in a bright silvery-white form at the cathode. An equally good deposit can be obtained from the solution first named with a current of only 1 ampère in density. Bubbles of hydrogen at the surface of the cathode are sometimes the cause of irregularities and roughness in the deposit. The preliminary experiments led to the performance of one on a larger scale, in which 0.50 kilo. nickel was deposited upon a cathode of 2 sq. decimetres superficial area. The solution used, contained 160 grms. of nickel per litre; the current density employed was 1.5–2.0 ampères; the temperature was maintained at 60° C.; and the E.M.F. required, with the electrodes at a distance of 4 cm., was between 1.0 and 1.3 volts. The nickel obtained was exceedingly tough, and the author concludes that, using hot solution, the electrolytic deposition of nickel upon any scale of operations is possible. An analysis of the nickel deposited in these experiments, showed that practically the whole of the iron and cobalt contained in the crude nickel had passed over to the cathode with the nickel. The author considers that in the sulphate solution no separation of these three metals is possible by alterations of the E.M.F. and current density employed. Such a separation is, however, possible according to Basse and Selve, and also to Vortmann, if the solution of the nickel salt be treated with tartaric acid and excess of sodium hydrate. The character of some of the alloys of nickel and iron obtained in the attempts to deposit nickel electrolytically from solution containing much iron, are described by the author.

In the experiments made with the nickel chloride salt solution, the electrolysis of the cold solution yielded similar deposits to those obtained from the sulphate solution. Heating the solution does not solve the difficulty, since a deposit of green basic chloride makes its appearance under these conditions at the cathode. This formation is prevented by the addition of 0.25 gm. of hydrochloric acid per 100 c.c. of fluid to the electrolyte. On account of the loss that occurs during the electrolysis of the hot solution, it is necessary to add fresh acid from time to time. Under these conditions entirely satisfactory deposits of nickel were obtained from solution containing 5–12 grms. of metal per 100 c.c., at temperatures ranging from 50° to 90° C., by means of currents of from 0.70 to 3.0 ampères in density. The deposit was lighter in colour and tougher, the greater the current density and the degree of concentration of the electrolyte. At temperatures below 50° C., the deposit was brittle, and dark grey in colour. The use of an acid electrolyte causes a greater evolution of hydrogen than in the

previous case, and the tendency towards roughness in the deposit is consequently increased. One experiment, in which filtering cloth was used to envelop the anode in order to retain the slimes, yielded a very brittle, scaly deposit of only one half the expected weight. Both the electrolyte and deposit were found to contain carbon; and the unsatisfactory nature of the deposit was ascribed to the passage of organic matters from the cloth into the hot electrolyte.

*Electrolysis with Carbon Anodes.*—The experiments made with carbon as anode did not yield successful results. The carbon disintegrated in the hot nickel chloride solution, and the effects produced in the electrolyte and upon the deposit of nickel were similar to those just described above. The author intends to continue these experiments with other forms of carbon, and also with lead peroxide as anode in a nickel sulphate solution. The conditions governing the electrolytic deposition of cobalt will also receive attention.

—J. B. C. K.

## PATENTS.

*Quantity of Metal which a Galvanoplastic Bath should Deposit on the Object treated, Apparatus intended to determine.* J. Ducot, Paris, France. Eng. Pat. 18,537, Aug. 21, 1896.

THE amount of metal to be deposited is determined by an automatic apparatus by a system of double weighing. The apparatus consists of a balance lever resting on two supports and a knife edge; the left portion of the lever carries a fixed counterweight, which it passes through lengthwise so as to produce a progressive resistance during the second weighing. The right arm of the lever is a rack bar, on which moves a sliding counterpoise, whereby the weight of the object treated is counterbalanced. From the same arm, and near its centre, is suspended a rod carrying the pieces which dip in the bath. The left arm carries a pointer, which moves over a dial until a movable handle is reached, which has been set at the predetermined weight. On the pointer and the handle making contact, an electro magnet is actuated which breaks the circuit and stops the deposition, simultaneously ringing a bell. The fixing in point of the balance is facilitated by an indented piece, and compensation in the motion of the lever is assured by the placing out of centre of the fixed counterweight, and by an indented bar secured diagonally on the sliding counterpoise, and further by a spherical regulator above the balance knife edge.—G. H. R.

*Metals or Alloys, Impts. in or connected with the Obtaining of, by Electrolysis or Hydro-electro-chemical Action.* P. Marino, Brussels, Belgium. Eng. Pat. 27,776, Dec. 5, 1896.

THE electro-depositing bath for a single metal may be made by mixing two solutions of salts of different acids of the same metal so as to produce double decomposition, or better results may be obtained by replacing one of the solutions by a solution of less than one equivalent of the salts of one of the alkaline earth metals or of lead, so as to produce incomplete double decomposition and a precipitate which is removed by decantation or filtration. In the case of alloys, the bath is composed of a mixture of the solutions of two salts of the respective metals, or of the metals and the salt of the alkaline earth or of lead, prepared as already described. Either before or after the incomplete double decomposition a saline solution or a mixture of saline solutions may be added to any of the baths prepared by this method, or free organic acids or free boric acid may be added to such baths.—G. H. R.

*Anodes, Impts. in, for the Electro-Deposition of Nickel.* T. R. Canning, Birmingham. Eng. Pat. 28,285, Dec. 10, 1896.

THE improved anode is built up of blocks or cubes of nickel just as they come from the refiner, except that they are moulded with suitably shaped recesses on two opposite sides, so that when the blocks are built up into an anode, vertical holes are formed between superimposed layers which serve to hold connections of carbon or other suitable material. The blocks are retained in a frame lined with carbon, and provided with carbon lugs, and having a

lattice or wicker-work front and a hinged back, so that the anode may be raised, and any individual block replaced as required.—G. H. R.

*Zinc. Impts. in Electrolytes for the Deposition of, and for Use in Secondary Batteries.* H. Leitner, London. Eng. Pat. 1572, Jan. 20, 1897.

This electrolyte is an improvement on that described in Eng. Pat. 24,173, Nov. 1896, and is composed as follows:—

Concentrated solution of zinc sulphate .....	50 parts.
Sulphuric acid (pure) .....	10 "
Concentrated solution of manganese sulphate.....	10 "
Ammonia alum in a concentrated solution, in which also a further amount of zinc sulphate has been dissolved.....	30 "

Zinc sulphate must be added, if necessary, till the solution approaches concentration. The solution may also be prepared by taking 9 parts of water with 1 of concentrated sulphuric acid, adding to this 1 part of concentrated solution of manganese sulphate, and saturating the resulting solution with crystals of zinc sulphate and alum, preferably ammonia alum. The electrodes, as described in the previous patent, consist of peroxide of lead plates, and plates of lead or other suitable base, which have been coated with zinc in the foregoing electrolyte, and this coating preferably consists of zinc layers, the first being slightly amalgamated with mercury before the second is given.—G. H. R.

## XII.—FATS, OILS, AND SOAP.

*Oils, Lubricating.* F. Jean. Rev. de Chim. Ind. 1897, 8, [91], 193—196.

THE author considers that a lubricating oil should have a fairly constant viscosity at 50° and 100°, and that oils rendered viscous by the addition of soap should be proscribed altogether.—C. A. M.

*Cerotic Acid and Ceryl Alcohol.* R. Henriques. Ber. 1897, 30, [11], 1415—1418.

IN the course of his work on cold saponification (this Journal, 1896, 299), the author examined two specimens of Chinese wax obtained directly from China. Of these, one melted at 81·5° and had a radiating crystalline structure, whilst the other was more granular, and melted at 83°. Both contained ceryl cerotate as their chief constituent. After four crystallisations from petroleum ether, boiling from 115° to 135° C., this ester was obtained pure. Its melting point was 81·2° (Brodie, 82°), and its saponification number 73·6. The latter value was determined by dissolving 3 grms. of the ester in hot petroleum spirit, adding 25 c.c. of normal alcoholic soda, and either leaving for 24 hours in the cold or boiling for an hour under a reflux condenser. The excess of alkali was then titrated back with seminormal alcoholic HCl, since the aqueous acid was found to give erroneous results, owing to the ready decomposition of cerotic salts by water.

The formula given by Brodie for ceryl cerotate,  $C_{31}H_{53}O_2$ , corresponds to a saponification value of 71·1, whereas the author's saponification value corresponds to the formula  $C_{32}H_{55}O_2$ . Hence it was considered that Brodie's for-

mula was doubtful, as well as his formula for cerotic acid ( $C_{27}H_{51}O_2$ ) and ceryl alcohol ( $C_{27}H_{53}OH$ ). C. Hell and O. Hermanns (Ber. 13, 1721) also expressed doubt as to Brodie's formula for cerotic acid, and more recently Marie (Ann. Chim. Phys. 29, [7], 145) came to the conclusion that it should be  $C_{28}H_{53}O_2$ . To decide as to this point, the author prepared pure cerotic acid (see this Journal, 1890, 661) and ceryl acetate, and determined their saponification values. The pure ester was saponified, and the cerotic acid precipitated as the calcium salt, which was washed, dried, and extracted with acetone, the acid being liberated from the residual salt and purified by crystallisation from benzene or acetic acid. It melted at 78°·5 (Marie found 77°·5, uncorrected), and gave, as the mean of six determinations, a saponification number of 140·9. Hence its formula was  $C_{28}H_{53}O_2$ , which has by theory 141·4 for its saponification value.

The ceryl alcohol in the saponified ester was converted into the acetate by means of acetic anhydride, and this was purified by crystallisation from benzene. It then melted at 63°·5 and had a saponification value of 131·4, corresponding to the formula  $C_{26}H_{53}O_2$ , with a theoretical saponification value of 131·1. According to this the formula for ceryl alcohol is  $C_{26}H_{53}O$ , and for ceryl cerotate  $C_{26}H_{51}O_2$ .  
—C. A. M.

*Soaps, Disinfectant.* S. Rideal, Brit. Pharm. Conference, Aug. 1897. Pharm. J. 1897, [1416], 158—160.

AN oleic acid soap is stated to be preferable to one containing palmitic or stearic acid, as the sodium salts of the latter separate out on the addition of hot water. Superfatted soaps are practically useless for disinfectant purposes, since the free fat hinders the action of the disinfectant.

Sulphur and alkaline sulphides blend well with soap, but the former, even as milk of sulphur, is very slow in its action, on account of its insolubility. The principal objection to alkaline sulphides is, that a prominent feature of their antiseptic action is the gradual evolution of sulphuretted hydrogen. With regard to metallic soaps, if an internal effect is wished for, a metallic oleate soap will succeed, but if a local disinfectant or antiseptic action be required, a mixture must be used, such as a mercuric iodide soap (in which the mercury is incorporated in the form of the double iodide of mercury and potassium) or a zinc soap, in which the metal is added in the form of a neutral zincate solution, which will yield the metal in a soluble form to water. Carbolic and cresylic soaps, which are usually sold as of 10 per cent. strength, frequently contain much less of the disinfectant. All soaps of this form have a pronounced odour, and soaps containing homologues of cresol always possess a tarry odour, even when disguised by the addition of eucalyptus, gaultheria, or other scents. Ethereal oils have such a low antiseptic value that, to be effective, they require to be used in such quantities as are liable to cause serious irritation to the skin.

Different medicated soaps were examined bacteriologically in comparison with a curd soap containing 32·5 per cent. of water and 60·8 per cent. of fatty anhydrides, using for the experiments a 2 per cent. solution. Inoculation with active bouillon cultures gave results which are summarised in the following tables, a + sign indicating growth and a — sign sterility:—

### I.—*Bacillus Coli Communis* in Viscous Growth.

Time.	Curd Soap.	A Scented Curd Soap.	Carbolic, 10 per Cent.	New Disinfectants.		HgI <sub>2</sub> , 3 per Cent.	Formalin, 0·4 per Cent.
				A.	B.		
5 mins. ....	..	..	..	..	..	—	+
15 " .....	..	..	..	..	..	—	+
25 " .....	..	..	..	..	..	—	+
30 " .....	+	+	+	+	+	—	—
1 hour .....	+	+	+	+	+	—	—
1½ " .....	+	+	+	+	+	..	..
2½ hours .....	+	+	—	+	+	..	..
3½ " .....	+	+	—	+	(Much attenuated.)	..	..
4 " .....	—	—	—	—	—	—	..

II.—*Staphylococcus Pyogenes Aureus*.

Time.	Curd Soap.	A Scented Curd Soap.	Carbolic, 10 per Cent.	New Disinfectants.		HgI <sub>2</sub> , 3 per Cent.	Formalin, 0.4 per Cent.
				A.	B.		
10 mins. ....	+	+	—	+	+	—	+
20 " .....	+	+	—	+	(Alternated)	—	+
30 " .....	+	—	—	—	—	—	—
Between 1 and 4 hours	—	—	—	—	—	—	—

The soaps were tried as sold. The relative amounts of disinfectants present in the solutions of the same strength (2 per cent.) would be carbolic, 0.2 per cent., or 7 in 500 of phenol; A, 0.06 per cent., or 7 in 1,666 of phenol; B, 0.03 per cent., or 7 in 3,332 of phenol; HgI<sub>2</sub>, 0.06 per cent., or 7 in 1,666 of HgI<sub>2</sub>; formalin, 0.008 per cent., or 7 in 12,500 of formaldehyde.

It was further found by bacteriological tests that many of the so-called disinfectant soaps have little, if any, greater germicidal action than good curd soap itself.—A. S.

## PATENTS.

*Soap, Impts. in the Manufacture of, and in Frames used in the Manufacture of, and in the Method of Cutting or Slabbing.* H. Hadfield, Whaley Bridge, Chester. Eng. Pat. 19,903, Sept. 9, 1896.

In place of the ordinary frame with removable sides and ends, the patentee employs a frame cast in one piece, or built up in sections, and fitted with a false bottom capable of being raised or lowered by chains, bands, hydraulic pressure, &c. This is used in combination with an arrangement of cutting wires with which the soap comes in contact when raised from the frame, and by means of which it is cut into slabs, &c. Another cutting frame with the requisite number of wires, and provided with a longitudinal movement, completes the division into bars when the soap has been raised to a sufficient height.—C. A. M.

*Soap, Dry, or Soap Powder; Impts. in the Manufacture and Production of.* F. W. Wright and The United Alkali Co., Ltd., both of Liverpool. Eng. Pat. 23,025, Oct. 16, 1896.

A Mixture of ordinary soap with crude bicarbonate of soda (as obtained in the ammonia-soda process), dried either by the addition of anhydrous monocarbonate of soda or by gentle heat.—C. A. M.

*Soap, Impts. in the Manufacture of.* E. G. Scott, Liverpool. Eng. Pat. 26,285, Nov. 20, 1896.

THE improvement, which relates to the manufacture of soft soap, consists in separating the oil or oils into glycerin and fatty acids by means of superheated steam or otherwise, recovering the glycerin and saponifying the fatty acids.

—C. A. M.

*Fragrant Substances, Method of Producing Highly Concentrated Fat Solutions of.* H. Mack, Ulu-on-the-Danube. Eng. Pat. 8387, April 1, 1897.

A SOLUTION of the fragrant substance in alcohol is diluted with water and shaken up with a scentless fat or with vaselin, so as to extract the perfume. The fat or vaselin, with the fragrant substance in solution, is separated from the liquor, and mixed with a "pulverous" material, such as starch, for use as a washing substance.—C. A. M.

*Soap, Improved Process for Making.* R. Gesell, Berlin. Eng. Pat. 17,783, July 29, 1897.

SOAP mass mixed with pulverised wood fibres, impregnated with a suitable antiseptic and (or) perfume, together with pulverised bran, oatmeal, and asbestos, in suitable small proportions.—C. A. M.

## XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

## (A).—PIGMENTS, PAINTS.

*Paint Trials.* M. Toltz. Chem. News, 1897, 76, [1970], 104; and J. Assoc. Eng. Soc., June 1897. A paper read before the Civil Engineers' Society of St. Paul, Dec. 7, 1896.

THE author tested the following paints as to their comparative value for protecting iron surfaces:—True asphaltic varnish paints; so-called asphaltic varnishes of inferior qualities; black carbon paints, of which the vehicle is practically a varnish; iron oxide paints; and graphite and silica graphite paints. Red lead was not tested, as, although it is still used to a certain extent, it is generally mixed with graphite. To ascertain the resistance to moisture, a set of sheet-iron dishes, 12 ins. in diameter by 0.5 in. deep, were painted, the scale or skin being first carefully removed. Two dishes were coated with each kind of paint, one receiving one coat, and the other two coats, the first being allowed to dry at least a week before the second was laid on. When the paint was perfectly dry, a given amount of water was placed in the dishes and allowed to evaporate at the ordinary temperature, this being repeated until the dishes showed more or less rust. After most of the water had evaporated, there remained, at the junction around the edge, a thin film of water, which, in contact with the carbonic and other acids of the air, acted on the paint in such a way that the iron beneath it began to rust. In actual practice, the same thing happens, except that the rust extends under the paint, and does not show as plainly as on the dish. Only paints which will withstand this test, are stated to be desirable for the protection of iron and steel structures. The cheap asphaltum paints and iron oxide paints failed under this test. Sheet iron, coated with the various kinds of paints, was also exposed to a temperature of 220°–300° F., for the purpose of ascertaining whether they would keep their elasticity or become so brittle as to be easily removed from the surface.

As a result of the experiments made, it is stated that iron oxide paints are not very desirable, at least for the first coat or two, for iron or steel; but as a third coat, for the protection of the underlying paints, they may be recommended. However, as graphite paints in paste form, well ground and mixed with boiled linseed oil, do not cost very much more than the cheapest iron oxide paints, they are recommended in preference to the latter for the second or third coat, as, if properly applied, they withstand the action of moisture much better. Asphalt varnish paint or carbon paint is recommended for the first coat, but the surfaces of iron and steel must be as free from moisture as possible while the structures are being painted, otherwise there is great danger that the coating will not adhere very firmly, and the value of the paint will thus be nullified. This precaution is less important in the case of iron oxide or red-lead paints simply mixed with linseed oil, as the latter readily absorbs moisture, whilst carbon and asphalt paints do not; but the lack of this property in the two last-named paints is one of the principal reasons why they are

superior to any other class. The author describes in detail a system for efficiently protecting iron and steel structures by successive coats of paint.—A. S.

# PATENTS.

*Lead Sulphite for Use as a White Lead Pigment, A Process for the Manufacture of.* A. C. J. Charlier, Glasgow. Eng. Pat. 19,788, Sept. 8, 1896.

A CURRENT of sulphurous acid gas is led, at a pressure of 10 or 20 lb. per square inch, through a number of vessels containing finely ground lead oxide, made into a paste with water, and maintained at "the proper temperature" by means of steam coils and agitators. The operation may be conducted so as to produce either a basic or a normal sulphite of lead; and if the former, it may be neutralised with sulphuric acid in order to yield a mixture of sulphite and sulphate. If preferred, carbonic acid may also be introduced simultaneously into the vessels, when the resulting precipitate will consist of the carbonate as well as the sulphite. The advantages of the sulphite of lead are said to be that it is non-poisonous, and has greater covering power and body than any other white lead at present manufactured.—F. H. L.

*Zinc-White, Impts. in the Manufacture of.* H. H. Lake, London. From G. Harmegnies, Brussels. Eng. Pat. 23,716, Oct. 24, 1896.

WASH. zinc ("rag-picker's zinc") is dissolved in hydrochloric acid, the solution filtered, decomposed with the theoretical quantity of magnesia, and the oxide washed and dried. The process is stated to be more economical than the usual method of distillation in air, inasmuch as the hydrogen can be burnt, and the filtrates and washings containing magnesium chloride may be concentrated to a density of 1.4, and then heated to 250° C. to regenerate fresh acid and magnesia. Presence of lead in the original zinc is immaterial; but if the solution contain more than 0.5 per cent. of iron, it should be removed by means of zinc oxide.—F. H. L.

*Paint for Ships' Bottoms, An Improved.* G. L. Burnham, Providence, U.S.A. Eng. Pat. 2108, Jan. 26, 1897.

10 GALLS. of linseed oil are boiled for five hours at 315° C. with 8 oz. of litharge and 8 oz. of lead acetate. When cold, the varnish is diluted with oil of turpentine to working consistency; and it is then mixed with "1 pint of seaweed, which is first ground—while green and wet, just as it is picked from the seashore—with oil." The composition is stated to yield a smooth enamelled surface, and it is also claimed to be an effectual preventative against barnacles and worms.—F. H. L.

*Enamel Paint, and Method of Applying the same, An Improved.* F. Boyling, Brisbane, and C. L. Garland and A. Ogden, Sydney. Eng. Pat. 14,105, June 9, 1897.

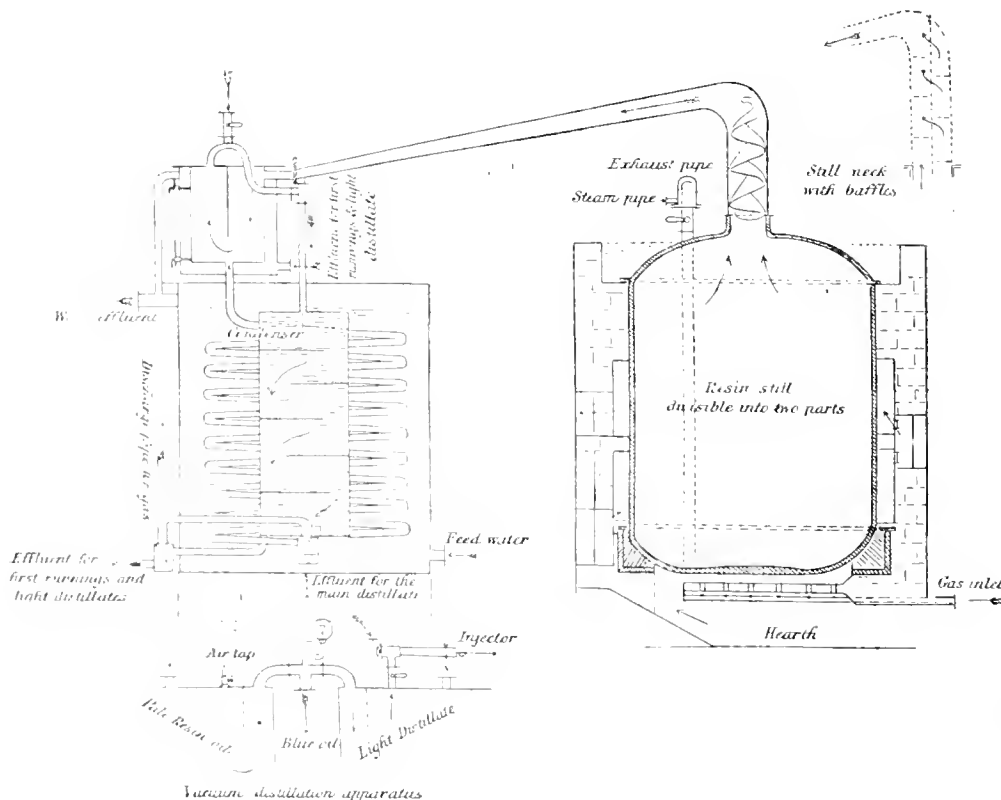

The desired pigment, suspended in gold size, is mixed with carriage varnish to a thin paste, about 20 per cent. of a 5 per cent. solution of shellac in methylated spirit introduced, and the whole thinned to working consistency with the carriage varnish already employed. For use on leather, 10 per cent. of raw linseed oil is added, and the material is stoved at 60° C.; but in the case of metal, the temperature should be about 120°. The composition may also be employed without stoving, like an ordinary paint, or as a coating for ships' bottoms.—F. H. L.

## (B.)—RESINS, VARNISHES.

*Crude Turpentine and Resin, Impts. in the Treatment of.* Fr. Boleg. Chem. Rev. Fett- u. Harz-Ind. 4, [12], 159–161; [13], 173–176; [14], 187–189; [15], 201–205; [16], 218–220.

*Resin Distillation.*—The best form of still is said to be a cylindrical vessel capable of holding 5 tons of resin when three-quarters full (73 by 92½ ins. without the lid dome), preferably in two parts, and made either of cast-iron or iron plate, with cast rounded bottom. The cast-iron lid is 12 to 14 ins. high, rounded, and attached by screwing. It is fitted with a manhole, safety-valve, and a central flanged

Fig. 1.

pipe, 8–10 ins. high and about 14 ins. inside diameter, to support the copper neck, which, in order to facilitate the production of thin oil free from resin, should be at least 40–60 ins. high, and be fitted with ladders extending up to the bend and causing the vapours to pursue a spiral course. The neck tapers down to a diameter of  $2\frac{1}{2}$ –3 ins. at its junction with the condenser. For the latter a simple worm condenser is insufficient for the production of better-class oil, and a double condenser is requisite, of the kind shown in the annexed figure, wherein the first runnings—acid water and strong-smelling light oils—can be passed through a separate apparatus to that used for the main distillate. Moreover, the pungent green oil coming over last of all must be led into an entirely separate condenser.

With this apparatus a simple fractional distillation is generally effected, and is usually sufficient. For special purposes, however, and particularly in the production of *drying oils*, a partial vacuum, equivalent to 15–25 (more rarely 50–60) c.m. of mercury, is produced by means of an exhaust attached to the receiver. This arrangement is also useful for certain purposes of rectification, 3–5 per cent. of fresh powdered lime being at the same time used to ensure sufficient decomposition of the distillate.

In large distilleries the only suitable method of firing, is to combine coal with resin gas. The bottom of the still is protected from the direct contact of the flame by means of a firebrick arch or dome, and the hearth must be long and broad, and not at too great a distance from the arch. A mixture of lump coal with nuts and smalls is recommended for firing, the proportion of the latter increasing as distillation progresses. The gas jets must be situated close under the arch, and adjoining the openings therein. By an intelligent use of gas-firing, as much as one-third of the coal bill can be saved, and a considerable quantity of resin spirit (pinolin) recovered. The best form of flue round the cylindrical part of the still, is one 6 ins. wide by 18 ins. high, running once forwards and once back, on either side, and closed with dampers.

The still being charged with resin, and the fire kindled, a saving of time is effected by pouring in from  $2\frac{1}{2}$  to 5 per

cent. of pale paraffin oil, of suitable density and boiling point, which will prevent the frothing up and boiling over, due to water in the resin, and will thus enable the still to be closed at once. This addition, moreover, ensures an additional 5 per cent. in the yield of pale distillate. The products obtained are: resin essence (pinolin) and acid water, 6–8 per cent.; pale resin oil, 50–55 per cent.; "blue" oil for refining or wagon-grease making, 20–15 per cent.; "green" oil for wagon-grease or carbolinum, 6–7 per cent.; gas, 5–7 per cent.; loss (and worthless residue), about 10 per cent.

If the still be charged overnight and the fire banked up under the melted resin, work can begin at 5 a.m., and the distillate will begin to run in about  $1\frac{1}{2}$  hour's time. By 8 p.m. (or two hours earlier when working with a vacuum) everything will have passed over except the green oil, which is transferred to a special still either the same night or early next day, and the resin still recharged at once with ready-melted resin, or opened and well aerated to prevent risk of explosion, and then filled as before. In this way the stills can be worked four times a week without night work, thus saving fuel, labour, and wear and tear. The residues from eight distillations are united and distilled for "green" oil in smaller cast-iron stills, the pitchy residue being used for making laquer for ironwork, shoemakers' pitch, &c.

*Treatment and Utilisation of the Resin Spirit (Pinolin).*—The rectification of the crude spirit is preferably carried out by the aid of direct and indirect steam, a vacuum, and a double condenser. This ensures a paler, purer, and milder product than by the ordinary method, and an increase of 5–7 per cent. in the yield. Instead of selling this spirit it can be advantageously worked up by treating it with direct steam and 3–3½ per cent. of soda lye of 36–40° B., at a temperature of 80–100° C., carefully removing the lye, washing with lukewarm water, and then mixing with 2 per cent. of sulphuric acid of 66° B. (at 15°–25° C.). After the acid has settled down—in 3 to 4 hours—another 2 per cent. of soda is added, to effect thorough neutralisation, and the spirit is finally rectified, like oil of turpentine, *in vacuo*, by direct and indirect steam, and  $\frac{1}{2}$  per cent. of soda or 3–5

Fig. 2.

per cent. of lime water. The resulting product is very similar to commercial oil of turpentine, and may be still nearer approximated thereto by an admixture of true oil of turpentine, essence from root-stock- or wood-tar oil, or crude turpentine, either before or during rectification. A considerably enhanced value is thus obtained, the product being fit to serve either as an adjunct to, or substitute for, oil of turpentine, and sure of a more ready sale than resin spirit of the ordinary quality.

No success has attended the attempts hitherto made to recover the washing lyes or the waste products therein, though the lye used for the second washing can be employed for the first washing of the succeeding batch of spirit.

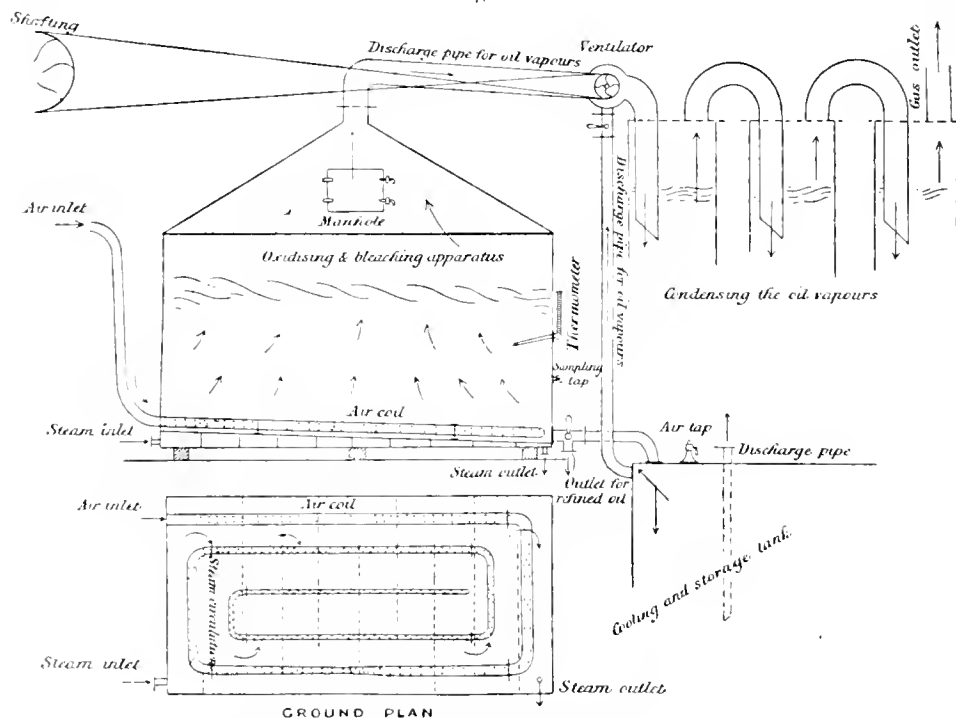

**Refining and Utilising the Resin Oils and Waste Products.**—The fractions refined are the pale yellow or "blonde" oil and the blue oil. When distilled in the apparatus already described, they will not require a preliminary rectification, since the percentage of saponifiable resin constituents does not exceed 10–14 per cent., as compared with 20–26 per cent. in the crude oils from the ordinary distillation methods.

The apparatus consists of a washing tank, 120 by 60 by 60 ins. (Fig. 2), and a bleaching tank of similar size (Fig. 3).

A 5-ton charge of "blonde" oil being placed in the former to allow the acid water to settle, about  $\frac{1}{4}$  part of hot water is added, and the whole boiled a short time by direct steam, to facilitate the operation. When freed from the acid water the oil is again boiled by direct steam, and treated with 4–5½ per cent. of soda lye of 36°–40° B. sprinkled over the surface, the heating being continued until a sample shows the oil to be free from resin and acid, whereupon the steam must be instantly shut off, or the product will assume a dark colour and turbidity due to dissolved resin soaps. For the same reason the steam coil should be at once lifted out of the liquid, by means of the stuffing-box arrangement *a, b* (Fig. 2), and cleaned by a short blast of steam before being used again. By taking this precaution a second vessel for the final washing may be dispensed with, and a clearer and paler product obtained.

At the end of an hour's time the water is drawn off, and the oil washed again by about 33 per cent. of water at 50°–60° C. and direct steam (the temperature not to exceed 105°) until a sample clarifies quickly. In case the operation does not require repeating, the oil, after the water has subsided, is drawn off into the bleaching and oxidising apparatus (Fig. 3), where it is warmed up to about 60° C. by indirect

Fig. 3.

steam, and in this condition treated for 2–3 hours with air blown in by a fan through a perforated coil, the evolved gases being removed by another fan at the top of the apparatus and conveyed to the condenser. The temperature of the oil is then raised to 115° C. in about an hour, and the treatment continued for a further 15–30 minutes, until the oil is debloomed and the vapours assume an odour of camphor or peppermint. In order to render the oil inodorous, it is necessary to continue exhausting the vapours until the temperature of the oil has fallen to about 30° C., and the addition of 10–15 per cent. of salt water during the bleaching process exerts a favourable influence, by preventing the renewed formation of oxide- and empyreumatic resins, which otherwise occurs, the formative substances being absorbed and removed by the brine. The oil thus treated will be found free from resin and acid, and suitable for the preparation of drying-oils for varnish-making.

In refining rectified blonde oil, the same treatment is applied, except that only 3–3½ per cent. of lye will be

needed, and that the final bleaching temperature should not exceed 105° C. Blue oil requires 3–4 per cent. of lye, and must be refined directly after distillation or rectification, in order that the product may be clear and not too dark.

Concerning the recovery of the waste products of the refining process, the acid water is united with that from the distillation and from the pinolin, and in small works is used to decompose the resin soap lyes. In large works, however, it is more advantageously purified, concentrated, and worked up in the manufacture of acetic acid, pyroligneous acid, or acetates. The resin soap lyes are boiled for about five minutes by direct steam, and left for an hour. The oil collecting on the surface is removed, to be returned to the washing tank, and the residue treated by blowing in steam and carbon dioxide (preferably liquid commercial) until the thick oil is separated from the residual (soda) lye. The former is either redistilled for refining or sold for making waggon grease, and the lye is causticised and used again. In smaller works the thick oil is separated by means of the

acid water in a similar manner, but in this case the residual liquor is valueless.

Some of these resin soap lyes can be utilised for facing certain common grades of paper, as also for cheap resin-curd and soft-soaps, disinfectants, and in the manufacture of water-glass; so that there is no waste. The light essences and vapours collected from the bleaching tank are mixed with the crude pinolin, to be decomposed into spirit and oil.—C. S.

**Varnish, Gold-coloured; for Tin-Plate.** Dingler's

Polyt. J. 1897, 305, [7], 168.

For the preparation of this varnish, 50 grms. of crystallised copper acetate are ground to a very fine powder in a porcelain mortar, and the powder is spread on a flat plate, and kept for some time in a warm place. The water of crystallisation and part of the acetic acid are thus volatilised, and the light-brown powder obtained, is triturated with oil of turpentine, and finally to the mixture is added with constant stirring, 150 grms. of copal oil varnish, warmed to 70° C. The copper salt, if it has been well ground, dissolves fairly well with stirring in a quarter of an hour, and the varnish is kept in a warm place for some days, with frequent agitation. The tin-plate is coated evenly with the varnish and then dried in an oven, and the tone of colour depends on the heating: a greenish colour first forms, changing on stronger heating to yellow and dark yellow, then to orange, and finally to reddish brown. The colour is fast to daylight, and better than the English gold lac with regard to fire. If the copal varnish used be of good quality, the varnished tin may be pressed and bent in any shape without injury to the coating. To produce a green colour, the metal is given five coatings, letting each one dry before the next is applied, and the varnished plate must be dried by only a mild heat.—A. S.

**Balsams, Resins, and Gum Resins.** K. Dieterich. Chem. Rev. Fett- u. Harz-Ind. 4, [15], 205, and [16], 215.

See under XXIII., page 829.

**PATENTS.**

**Manufacture of Sealing Wax, Impts. in the.** P. S. Watkins and P. J. Nunn, London. Eng. Pat. 15,180, June 24, 1897.

This patent refers more especially to the cheaper kinds of sealing wax, such as those used for bottles, &c., and the improvement consists in simply mixing the powdered ingredients together instead of melting them and casting the product into cakes or sticks, as is the usual custom.

—F. H. L.

**Compositions containing Nitrocellulose and in Articles treated therewith, Impts. in.** P. M. Justice, London. From "The Marsden Company," Philadelphia, U.S.A. Eng. Pat. 17,602, July 27, 1897.

For use as a waterproofing composition, 100 parts of a solution of nitrocellulose are mixed with 55 parts of linolin, and the whole spread over the desired material in the usual manner, or made into thin sheets by allowing it to dry on glass plates, from which it is ultimately stripped. As a flexible covering for leather, &c., 12 oz. of nitrocellulose are dissolved in 1 gall. of amyl acetate, 10 oz. of linolin, and 3 oz. of "corn oil" added, and finally some colouring matter, such as aniline black, introduced.—F. H. L.

**(C.)—INDIA-RUBBER, &c.**

**Rubber Hose, Mending Cracked.** Leipziger Färber Zeit. 46, [7], 312.

To mend cracked rubber hose, the damaged part, previously well cleaned and dried, is painted over with hot oil of turpentine. A thin sheet of gutta-percha, softened by heat, is put round it so that the edges meet, and is pressed against the hose with a knife blade. The edges are finally cemented together by touching the seam with a moderately hot iron rod.—I. S.

**Gutta-Percha.** J. A. Montpellier. Rev. de Chim. Ind.

1897, 8, [91], 250—204.

GUTTA-PERCHA was first introduced into Europe by Joseph d'Almeida in 1843. It is contained in the milky juice of

a variety of *Isonandra-gutta*, a tree belonging to the genus *Bassia butyracea*, which occurs principally in the Dutch Indies, Malacca, and the Malay Archipelago, where it attains a height of 40 feet.

The natives formerly extracted the juice by felling and barking the trees, but it is now collected in a similar manner to caoutchouc, by making incisions and collecting the exuding juice. This consists of an aqueous and a pasty portion, the latter constituting the gutta-percha. When sufficiently coagulated it is separated from the liquid portion by squeezing with the hands. In another method, now abandoned, the juice was first gently warmed for several days in order to evaporate part of the aqueous liquid.

In 1888, Serullas undertook a mission with the object of attempting to acclimatise the *isonandra* in different colonies and of cultivating it on a large scale. From experiments on samples forwarded by him, Jungfleisch found that gutta-percha was present in all parts of the tree, and that it could be extracted by means of a solvent, such as toluene. The method now used industrially as the outcome of these researches consists in digesting and extracting the dried and powdered leaves with some such solvent at 100°, and removing the solvent by means of the prolonged action of low pressure steam. The yield varies from 9 to 10·5 per cent., and the product is much purer than the ordinary commercial gutta-percha, which has a reddish colour, due to the presence of fragments of bark, earth, &c. Shortly after this process was brought out, an analogous method was proposed by Diédonné Rigolet, in which the leaves were extracted with carbon bisulphide in a special apparatus.

Crude gutta-percha is of very varying quality, the most esteemed varieties coming from Singapore and Borneo. Much of the commercial article is not derived from the *isonandra* alone, but has been mixed by the natives with the juice of similar trees, and in all cases it requires cleansing from particles of bark and dirt. This is most simply effected by dividing it in a machine, and washing it first in a current of cold water and then in one of hot, which causes the denser foreign bodies to fall to the bottom. The cleansed gutta-percha is then kneaded in a special apparatus heated by steam, where it agglomerates and loses most of the water taken up in the washing.

As thus obtained, the purified gutta-percha is of a brown colour, conducts heat badly, and is readily electrified by friction. Between 0 and 2° it is very tenacious, elastic, and fairly supple; between 25 and 30° its flexibility increases, and when the temperature reaches 50° it can be easily flattened out. From 100° to 110° it fuses to a paste, boils at 129°, and is decomposed at 130°, yielding, on distillation, colourless oils, consisting for the most part of isoprene and caoutchine, whilst a residue of carbon remains in the retort. It does not possess the elasticity of caoutchouc, but, on the other hand, unlike that substance, does not lose its elasticity at -10°. It also differs from caoutchouc (which is apparently structureless) in having a cellular structure, which becomes fibrous when subjected to tension. It is very porous, so that its density often appears to be less than that of water.

Its best solvents are carbon bisulphide, chloroform, and toluene in the cold. It is partially soluble in anhydrous ether and alcohol, and in benzene at 25 and higher. It is readily soluble in warm essence of turpentine from a solution in which it can be precipitated with alcohol. Sulphuric acid (monohydrate) attacks it in the cold, liberating sulphur dioxide. Fuming nitric acid has a very energetic action upon it, liberating nitrogen peroxide, and producing, according to Oudemans, among other substances, formic and hydrocyanic acids. Hydrochloric acid attacks it slowly, changing its colour to brown, and making it friable. As it is not attacked by hydrofluoric acid, it is used for the manufacture of vessels to hold solutions of that gas. It resists the attack of different ferments, and is unacted upon by alkaline or saline solutions. When obtained pure by dissolving it in chloroform or carbon bisulphide, filtering, and allowing the solvent to evaporate, it is white or greyish-white and opaque, but under the combined action of light and air it alters, turning yellowish, hardening, increasing in weight, and becoming more soluble in alcohol. This

appears to be a process of oxidation, which is favoured by a suitable temperature (25—30°), and a fine state of division. It does not take place when the gutta-percha is immersed in water.

The first chemical re-search on gutta-percha was made by Payen in 1851, who found it to consist of three proximate constituents, which he named *gutta*, *albunc*, and *fluavile*.

—C. A. M.

#### PATENTS.

*Manufacture of India-rubber Substitutes as applied to the Covers or Jackets for Pneumatic Tyres, for Cycles, Carriages, and all Classes of Vehicles, Impts. in the.* J. Cooper, London. Eng. Pat. 17,387, Aug. 6, 1896.

This material consists of india-rubber 6 lb., gutta-percha 2 lb., magnesium carbonate 6 lb., antimony sulphide 2 lb., and shellac &c., together with sufficient sulphur and lime to vulcanize. If the composition is to be used for the manufacture of belts or packing, only one-half of the above mentioned amount of gutta-percha is employed.

—F. H. L.

*Gutta-Percha from the Leaves and Twigs of the Ictandra Gutta and Kindred Plants, Improved Process and Apparatus for the Extraction of.* Siemens Bros. and Co., Westminster, and E. F. A. Obach, Old Charlton. Eng. Pat. 19,046, Aug. 28, 1896.

THE stems and twigs are crushed in such a manner as not to produce any dust, and then extracted with light hydrocarbons of the paraffin series in steam-jacketed vessels fitted with inverted condensers. The extracts and washings are cooled to precipitate the gutta, and the latter is finally washed with fresh solvent till colourless. Melted paraffin wax can also be used as the extracting agent, for, on cooling, the gutta remains imbedded in the solidified hydrocarbon and protected from the air, so that it is convenient to handle. Separation is then effected by dissolving out the paraffin by means of petroleum spirit.—F. H. L.

*Elastic Filling, An Improved, more especially applicable for Cycle Tyres, Cycle-Handles, Cushions, and the like, and in the Method of Manufacturing the same.* J. Desbordes, Berlin. Eng. Pat. 8905, April 7, 1897.

It is proposed to fill tyres and saddle-cushions of bicycles, and cushions generally with a gelatinous or glutinous substance which has been transformed into a spongy or foamy condition by mechanical or other treatment. For this purpose 25 parts of gelatin are liquefied by heating, 25 parts of glycerin and  $\frac{1}{2}$  part of formaldehyde added to it, and this mixture, after being stirred or beaten into a frothy mass, is filled into the above-mentioned articles. Or, it is cast into appropriate moulds and the solidified castings are then provided with a tightly-closing cover of india-rubber or leather.—C. O. W.

*Extracting and Purifying Gutta Percha, Impts. in.* W. Ramsay, London. Eng. Pat. 17,936, July 30, 1897.

THE essential feature of this invention consists in the substitution of rosin oil for the toluene which is often employed in the extraction and purification of gutta-percha, *viz.*, Eng. Pat. 651, 1896 (this Journal, 1897, 521). The leaves, &c. are washed in alkali and water, extracted with rosin oil in a closed vessel at 80 to 130° C., the gums precipitated from their solution by acetone, and the latter recovered by distillation.—F. H. L.

### XIV.—TANNING, LEATHER, GLUE, SIZE.

#### PATENTS.

*Leather, a Substitute for, and Process of Manufacturing the same and other Analogous Substances.* From F. Billing and A. Letalle, Birmingham. Eng. Pat. 22,965, Oct. 16, 1896.

THE substitute is prepared by immersing sheets of cotton wool or other suitable fibrous material in a solution of gelatin and methylated spirits or naphtha which has been mixed in the form of spray by means of a suitable apparatus. The composition may be made supple by the addition of

treacle, glycerin, or like substances. It is dried and subjected to the action of a solution to coagulate the gelatin. Formalin, alum, tannic acid, or a mixture of such substances may be used. The product is dried and embossed with patterns between engraved plates, in imitation of morocco or other leather.—J. T. W.

*Tanning Process, An Improved.* From A. M. Clark. By Les Fils de F. P. Heurich, Schlettstadt. Eng. Pat. 24,812, Nov. 5, 1896.

THIS is a rapid tanning process in which naphthalene is added to the weak liquors. The hides are suspended successively in three tanning liquors containing naphthalene, of the respective specific gravities 1.2°, 2°, and 3° B. They are then transferred to a drum with a strong liquor of 15° B. also containing naphthalene. Five kilos. of naphthalene are used for about 17,600 gallons of liquor. The action of the naphthalene causes the grain to remain soft, and a thick ox hide can be tanned in 50 hours.—J. T. W.

*Tanning, Impts. in Processes of.* C. S. Dolley, Philadelphia, U.S.A. Eng. Pat. 12,099, May 15, 1897.

HIDES or skins, prepared in the usual way for tanning, are subjected to the action of an aqueous solution of formaldehyde, of a strength gradually increasing from 3 to 10 per cent. About one hour's treatment completes the process. Or, the hides are exposed in a close chamber to gaseous formaldehyde, either by itself or in conjunction with aqueous or alcoholic vapours.—C. O. W.

*Blood and other Albuminous Matter, Impts. in the Treatment of, both Animal and Vegetable, for Use in Manufacture and the Arts.* P. G. Sanford, London. Eng. Pat. 12,449, May 20, 1897.

THE invention consists in the treatment of animal or vegetable albuminous matter with ammonium fluoride, or ammonium, sodium, or potassium borofluoride.—C. O. W.

*Grease or Fatty Matter, Impts. in the Method of and Apparatus for Removing, from Sheep Skins and other Leather and the like.* W. Sagar, sen., A. P. Sagar, and W. Sagar, jun., Colue. Eng. Pat. 13,778, June 4, 1897.

A SPECIAL form of extraction plant for degreasing sheep skins and the like with suitable solvents at moderate temperatures and without undue waste of solvent.—C. O. W.

### XV.—MANURES, Etc.

*Mineral Phosphates [Manures], Estimation of Lime Aluminu, and Iron in.* L. Lindet. Comptes Rend. 125, [4], 246.

See under XXIII., page 828.

### XVI.—SUGAR, STARCH, GUM, Etc.

*Molasses, Commercial Analysis of.* M. Molhaut. Bull. Assoc. Belge de Chim. 11, [3], 86.

See under XXIII., page 830.

*Starch Manufactures, The Digestibility of certain By-Products of.* B. Schultze. Jahresbericht der agr. Vers. Station zu Breslau, 1896.

See under XVIII. A., page 820.

#### PATENT.

*Sugar, An Improved Process for Refining and Purifying.* G. Ranson, Phalempin, France. Eng. Pat. 19,815, Sept. 8, 1896. (See also this Journal, 1897, 688—689.)

THE syrup or sugar to be purified is made slightly alkaline with barium hydrate or sodium carbonate, and hydrogen peroxide added in the proportion of from  $\frac{1}{2}$  to 5 litres per 100 kilos. of sugar according to the colour of the product. The decolorisation is effected gradually. 100 grms. of finely powdered animal charcoal, from which all the phosphate has been removed by acid, to every 100 kilos. of sugar, is added, to expedite the liberation of oxygen

from the hydrogen peroxide so that the organic compounds capable of being decolorised may be oxidised. The excess of oxygen is removed from the syrup by adding hydrosulphites of aluminium, barium, &c., or an aqueous solution of hydrosulphurous acid, or by producing this acid in a nascent condition in the syrup.

To prepare the hydrosulphites of aluminium, barium, &c., the corresponding "bisulphate" (2 bisulphite) is placed in a vessel capable of being hermetically closed, the bottom of which contains powdered or granulated zinc. The reduction is allowed to proceed for 30 minutes, the liquid cooled, decanted, and added to the syrup. A solution of hydrosulphurous acid may be made by adding 20 grms. of zinc powder to a solution of sulphurous acid containing 100 to 200 grms. of acid per litre. To prepare nascent hydrosulphurous acid, sulphurous acid gas is passed into the syrup until the acidity is 0.1 to 0.2 gm. per litre, then 16 grms. of zinc powder are added for each 100 litres of syrup and the whole is stirred.

The two periods of oxidation and reduction leave an excess of sulphite in the juice, which is converted into sulphate by adding the necessary quantity of hydrogen peroxide. The temperature of the mixture is then raised to 78° C. and the syrup filtered. The heated mass being thus freed from solid substances, the excess of sulphurous acid escapes as soon as the liquid boils, becoming thereby alkaline and preventing inversion.

In purifying sugars by acid treatment the syrup is saturated at a temperature below 50° C. with sulphurous acid. The organic matter is decomposed, and the alkaline salts converted into sulphites, which latter are oxidised to sulphates by treatment with hydrogen peroxide. The syrup is filtered, and again saturated with sulphurous acid. 10 to 50 grms. of zinc powder to each litre of syrup are added, and the whole mixed for 15 to 20 minutes; nascent hydrosulphurous acid is formed, which effects decolorisation very energetically. The temperature is raised to 75° C. before filtering, because at this point the hydrosulphurous acid is decomposed, taking oxygen from the organic matter in the syrup. The peroxide of hydrogen must then be added in the same manner as in the first-mentioned alkaline process.

*Barley, The Cell-Wall dissolving Enzyme of.* F. Reinitzer. Wochenschr. f. Brau. 1897, **14**, 304—307. From Hoppe-Seyler's Zeits. f. Physiolog. Chem. 1897, **23**, 175.

THE author considers that the cystase which, according to Brown and Morris, is present in germinating barley, does not exist. The barley only develops diastase, which is able to dissolve cellulose or hemicellulose. The diastase of germinating barley possesses the property of dissolving certain very easily hydrolysable hemicelluloses, and by warming to 60° C. the author finds this property is weakened but not completely annulled. The hemicelluloses, which are easily hydrolysed, are very widely distributed in the vegetable kingdom: they connect the cell walls of the mealy portion

of the barley: they form the middle layers in the parenchyma of the potato tuber and carrot, and the walls of the young parenchymatous cells of germinating maize. There are also numerous hemicelluloses which are not attacked by the diastase of germinating barley. The walls of the aleurone granules of barley contain, besides small quantities of cellulose, a large amount of certain hemicelluloses. The grains in which these hemicelluloses are stored up as reserve material, in the form of the thickening of the cell walls, show, on germination, an enzyme different from malt diastase, and which might be known as cystase.—J. L. B.

*Diastase, The Solvent Action of, on Ungelatinised Starch.* E. v. Sigmond. Wochenschr. f. Brau. 1897, **14**, 412.

A REPERITION of Lintner's investigations (this Journal, 1890, 402) on the same subject, and carried out in the same way, the object being to determine the comparative resisting power of the starches (purified) from various cereals, to the solvent action of cold-water extract of malt, at temperatures ranging from 30—65° C. In the first place, it is stated that Lintner's *modus operandi* leads to unsatisfactory results, on account of the starch tending to form partially gelatinised lumps. A continuous stirring of the mash is essential in preventing this "lumping." The author's results differ from Lintner's, chiefly in the order of stability of the various starches. Thus maize starch is found to be far more readily dissolved than rice starch at 60 and 65° C.; whilst Lintner brackets the two as being equally resistant. Similarly, in opposition to Lintner, the author finds that rye starch is considerably less stable at 55 and 60° C. than wheaten starch.—H. T. P.

*Caroubinase: A New Hydrolytic Enzyme.* M. J. Effront. Comptes Rend. 1897, **125**, 116—118.

THE carbohydrate isolated from the seed of *serotonia siligua* (this Journal, 1897, 749) is readily hydrolysed by dilute acids and by the enzyme caroubinase. This enzyme is formed during the germination of the seed of the caroubi, and the transformation of the carbohydrate (caroubin) and the secretion of the enzyme may be observed on allowing the isolated embryo of the seed to germinate in the presence of caroubin. The liquefaction and absorption of the latter take place much more rapidly when chlorophyll is formed in the plant. Caroubinase acts energetically at 40°, and its action increases with a rise in the temperature to 45°—50°, which may be regarded as the optimum temperature; at 70° its action becomes very feeble, and at 80° the enzyme is destroyed. Its action is very feeble in a neutral medium, and is accelerated by the addition of 0.01 to 0.03 c.c. of formic acid to 100 c.c. of the liquid.—A. K. M.

*Cider, Salicylic Acid and Calcium Sulphite as Preservatives of.* E. H. S. Bailey and C. M. Palmer. Kansas University Quarterly, 1897, **6**, [3], 111—116.

IN order to determine the preservative action of salicylic acid and calcium sulphite, the following experiments were made:—Salicylic acid, in quantities varying from 1 part in 500 to 1 part in 20,000, was added to separate lots of fresh cider, which were then set aside at temperatures ranging from 12° to 22°. Portions of the cider were distilled at the intervals given in the table at the head of the next page, and the alcohol determined. With the last of these determinations the acidity was also estimated, and the acid was again determined two months later.

*Hydromel ["Mead"], or Honey Wine.* J. Graftiau. Bull. Assoc. Belge des Chim. **11**, [3], 82—97.

SINCE honey contains on an average between 80 and 85 per cent. of fermentable sugars, 1 kilo. will yield 480 c.c. of alcohol, and, consequently, to obtain 1 litre of alcohol, 2.08 kilos. of 80 per cent. honey must be taken; so that to prepare 100 litres of honey wort it is necessary to employ  $x$  2.08 kilos. of honey,  $x$  representing the percentage by

—A. K. M.

volume of alcohol desired in the finished hydromel. Moreover, owing to the absence of materials suitable for the nutrition of yeast, it is necessary to add a yeast food similar to that prepared for the purpose by Gâstine (*Comptes Rend.* 109, 479; this Journal, 1889, 910); otherwise the fermentation will be incomplete. There is no direct evidence that the ancients made or did not make any additions for this purpose; but their honey was less pure, and the fermenting vessels were put to other uses; hence a sufficiency of yeast food might easily be present. An addition of tartaric acid, to supply the requisite acidity for the development of the yeast, and of tannin for clarifying and preserving the wine, is also advantageous. Other conditions necessary to the normal course of fermentation are: pure water, clean vessels, absence of bad smells, the use of high-class yeast, maintenance at suitable temperature, and a sufficient degree of aeration.

From fermentations made on a small scale by the author at May in 1895–1896, with a wort containing 25 per cent. of honey and 5 grms. of Gâstine's yeast food per litre, the temperature being maintained at 25° C. (except one sample, kept at 10° C.), it appears that honey wort, whether sterilised or not, becomes infested with mould and ferments if exposed to the air; that cold restricts the fermentation; that the flavouring influence of the different yeasts employed was in this case masked by a bitterness of unknown origin, and not observed on other occasions; and that the proportion of honey was too low: the worts containing an addition of dried raisins or an extra amount of heather honey (30

per cent. in all) giving the best results—a circumstance explicable by the residual extract imparting fulness to the flavour.

In making a hydromel from honey and raisins, the yeast was prepared by exposing 500 grms. of white sultana raisins in 750 c.c. of sterile water to a temperature of 20°–25° C. for five days, with due precautions against infection. The wort was obtained by adding 5 kilos. of the same raisins and 22.5 kilos. of white honey to sufficient warm water to make a total volume of about 70 litres, which, after the solution of the honey, was pitched with the above leaven, and left to ferment at 20°–25° C. in closed vessels. At the end of three weeks, fermentation had subsided, and the first racking was performed, the pulp being pressed and the runnings returned to the bulk. Fermentation then proceeded actively for another week, and gradually terminated, whereupon 5 grms. of tannin were mixed in with the liquid, which was then bunged and placed in a cellar, where, after a second racking, it remained for a year, and was bottled. The resulting hydromel was between Madeira and Champagne in colour, full, of very fine flavour, and contained 13 per cent. of alcohol.

The author recommends the addition of honey to the juice of several varieties of fruit too poor in sugar to produce beverages rich in alcohol though containing an ample supply of yeast food, and he gives the following particulars of the sugar content of each, with the amount of honey to be added per 100 litres of juice:—

	Apple.	Pear.	Plum.	Sweet berry.	Strawberry.	Raspberry.	"Myrtle."	Large Gooseberry.	Small Gooseberry.	Raisins.
Sugar..... Per Cent.	10.18	18	6.5	10	6.5	4	5	7	6.5	15
Added honey..... Kilos.	20	12	23	20	23	26	25	23	23	15

He has also prepared a hydromel with malt wort, 2 litres; honey, 5 kilos; water, 15 litres; tartaric acid, 15 grms., which fermented satisfactorily, and yielded a very good beverage.—C.S.

*Wine, Presence of Acarina (Mites) in.* L. Mathieu. *Comptes Rend.* 1897, 125, [8], 100–101.

TROUSSART (*Comptes Rend.* 1897, 364) has pointed out that the sediment of wines produced from dried grapes

occasionally contains the remains of an acarina (*Carpoglyphus passalorum*). The author has frequently observed such remains, entire or fragmentary, in wines of undoubted purity (i.e., not produced from raisins), especially in white wines grown in the Champagne and Bordeaux districts. Two species of these mites have been identified (*Glyciphagus cursor*, Gervais, and *Tiroglyphus farinae*, de Gyer), being found in considerable numbers, and multiplying freely, in the growth of mould developed on the

corks of bottles stored horizontally in a dark situation. In a test tube, containing 2–3 drops of wine, these mites also develop rapidly, being able apparently to utilise directly the extractives of the wine for their sustenance. The remains of 50 mites, when macerated for several months with  $\frac{1}{10}$  litre of wine, did not impair its flavour in the least. The author concludes that the presence of nearina in a wine does not necessarily indicate its production from raisins. He is of opinion that their presence in the storage cellar may possibly bring about the dissemination of, and contamination of the wines with, *Mycoderma vini*.—H. T. P.

**Wine that has lost its Colour ("Casse"), Absorption of Oxygen in.** J. Laborde. *Comptes Rend.* 125, [4], 248.

WHEN wines that have deteriorated in, or lost colour ("casse") are repeatedly agitated by the injection of a known volume of air, absorption continues during four to eight days, and then ceases, the amount of oxygen taken up and of  $\text{CO}_2$  formed, being in three instances as follows:—

Sample.	O absorbed per Litre.	$\text{CO}_2$ formed per Litre.	Ratio ( $\frac{\text{O}}{\text{CO}_2}$ )
No. 1	C.c. 50.8	C.c. 32.4	0.563
" 2	" 81.0	" 38.0	0.717
" 3	" 110.2	" 63.8	0.758

The  $\frac{\text{CO}_2}{\text{O}}$  ratio, which is variable, and is greatest in the initial stage with wines much off colour, is always less than unity.

The effects of "casse" may be artificially produced by inoculations with leucase or with diastatic liquid from *Botrytis cinerea* (this Journal, 1897, 156), and this liquid is itself capable of absorbing 49.6 c.c. of oxygen and producing 13.8 c.c. of  $\text{CO}_2$  per litre—i.e., it acts very similarly to wine off colour, and, like the oxydase of the latter, thereby loses its oxidising power, probably as a result of the combustion of its elements.

Heat decreases the activity of the oxydase, the absorption of oxygen being found to be reduced to the normal when a wine liable to much deterioration through "casse" was heated in bottle to  $75^\circ\text{C}$ ., though at  $60^\circ\text{C}$ . the oxydase remained unaffected.

In the proposed remedial  $\text{SO}_2$  treatment (Bonffard), the absorption of oxygen remains practically the same as before, and since it is found that some of the  $\text{SO}_2$  is still unoxidised when absorption has ceased, it would appear that oxydase has a superior affinity for oxygen, and also that the undoubted efficacy of the  $\text{SO}_2$  is neither due to its oxidisability nor to destruction of the oxydase.—C. S.

See under XXIII., page 830.

## PATENTS.

**Pure Yeasts, A New or Improved Method of and Apparatus for the Manufacture of.** G. E. Jacquemin, Malzéville, France. Eng. Pat. 21,011, Sept. 22, 1896.

ABOUT a hectolitre of wort, or other fermentable liquid containing matter suitable for the nutrition of yeast, is carefully sterilised, cooled to  $28^\circ\text{--}30^\circ\text{C}$ ., and passed into a second sterilised vessel employed for the production of the first yeast. The selected pure yeast is introduced at the opening of the thermometer, the latter replaced, and the contents of the vessel aerated. When the fermentation is proceeding actively, the liquor is run into a third receiver of larger capacity than the second; sterilised wort is subsequently added and no augmentation of yeast effected. This product is aerated for about 12 hours, and a certain quantity drawn off into a fourth receiver, which is supplied with sterilised wort. In this way a third yeast is obtained, which, as soon as made, is directed according to the requirements of

manufacture into fermentation vats. The quantity of liquor containing yeast taken from the third receiver is replaced by an equal volume of sterilised wort.—J. L. B.

**Fruit Juices (Fruit and Grape Wines), Process for the Production of Non-Alcoholic or Feebly Alcoholic, which may be Kept or Preserved without Change.** H. Müller-Thurgau, Waedensweil, Switzerland. Eng. Pat. 978, Jan. 13, 1897.

AFTER the fruit juice, freed from skins and stones, is heated to  $60$  or  $70^\circ\text{C}$ . for half an hour in a closed vessel, it passes into a sterilised settling vat; the juice is then filtered, and sterilised by heating to  $60\text{--}70^\circ\text{C}$ . If the product is to be naturally coloured, the juice is heated and passed through a receiver containing the skins, the subsequent treatment being the same as above. On the other hand, the juice and skins are heated together, the latter separated, and the filtered liquor sterilised. Should a small amount of alcohol be necessary, fermentation is allowed to proceed to the desired extent prior to the first heating.

—J. L. B.

**Wine, Beer, and Other Liquids; Protecting Bottles and their Contents against Injury or Loss during the Operation of Sterilising or Pasteurising; A Method or Means of.** C. Ameye, Issegheem, Belgium. Eng. Pat. 16,091, July 6, 1897.

A DOUBLE wire, bent over in the form of a hook at one end, is suspended inside the neck of the bottle before the cork is inserted; the minute passage thus formed permits the escape of steam, carbonic acid, &c., and prevents the accumulation of pressure within the bottle. After sterilisation is finished, the wire is withdrawn and the cork pushed home.—L. A.

## XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A.)—FOODS.

**Lupin Seeds, The Proteids of.** T. B. Osborne and G. F. Campbell. *J. Amer. Chem. Soc.* 1897, 19, 454–482.

BOTH the yellow and blue lupin have long been cultivated in Europe, on account of their readiness to flourish on sandy or gravelly soils. By their help, poor or "worn out" land has been rendered fit for agricultural purposes, as these plants furnish much fodder, and when ploughed in green, they rapidly impregnate the soil with humus.

Ritthausen (*J. Prakt. Chem.* 103, 78; *ibid.*, New Series, 24, 222, and 26, 442) found the characteristic proteid of yellow and blue lupin seed to be conglutin; his preparation from the yellow lupin contained 1 per cent. of sulphur, whilst that from the blue variety contained 0.5 per cent.; in other respects the two conglutins were similar. This author also obtained a body which he believed to be legumin.

The authors find that both yellow and blue lupin seeds contain very little proteid matter soluble in water, that of the yellow lupin amounting to 0.37 per cent. A part of this consists of proteose, but whether the remainder is albumin or a globulin soluble in very dilute salt solutions, was not determined. Peptone is not contained in the freshly ground seed, but is formed in small quantity after prolonged contact with water. The greater portion of the proteid matter contained in these seeds is soluble in saline solutions, the yellow lupin yielding 26.2 per cent. of conglutin. Preparations from the blue lupin are usually much purer than those from the yellow, for the latter contain a considerable quantity of a substance containing sulphur, from which conglutin may be separated by fractional precipitation of dilute salt solutions. This explains why Ritthausen's conglutin (*loc. cit.*) from the yellow lupin contained twice as much sulphur as that from the blue lupin. When purified, no difference in properties and reactions could be detected between preparations from the two seeds.

The conglutin from the yellow and blue lupin were found to contain carbon, 50.91, 51.13; hydrogen, 6.88, 6.86;

nitrogen, 17.93, 18.11; sulphur, 0.52, 0.32; oxygen, 23.76, 24.58 per cent. respectively. Conglutin is easily soluble in sodium chloride solutions containing above 5 per cent. of salt. On dilution it is precipitated. In a salt solution it is apparently unaffected by prolonged heating in a boiling water bath; but, on standing, a solid opalescent jelly is formed, which becomes clear and fluid on again heating. Unlike other globulins, conglutin does not yield insoluble (coagulated) products by washing with alcohol after drying.

The preparation of proteid soluble in 0.2 per cent. potash, gave the following numbers on analysis:—Carbon, 51.40; hydrogen, 6.79; nitrogen, 16.13; sulphur, 1.03; oxygen, 24.35 per cent. Owing to the insolubility of this substance in any medium but alkalis, and the difficulty of making pure preparations, nothing further was learned respecting it.

—J. L. B.

*Starch Manufacture, The Digestibility of certain By-Products of.* B. Schmitze. Jahresbericht der agr. Vers.-Station zu Breslau, 1896.

By artificial digestion with gastric juice and pancreas secretion, it was found that 98 per cent. of the proteids of gluten meal, obtained in the manufacture of wheat starch, and 76 per cent. of the proteids of molasses pulp (89 per cent. of potato pulp and 20 per cent. of molasses) were rendered soluble. These two substances are therefore useful foods.

—A. L. S.

*Cow Pea, The Proteids of the (Vigna Catjang).* T. B. Osborne and G. F. Campbell. J. Amer. Chem. Soc. 1897, **19**, 491—500.

As a result of these experiments the authors conclude that the principal proteid of the cow pea is a globulin, much resembling the legumin of the pea and vetch, but differing from them in composition and properties. It is named vigin. On analysis this proteid was found to contain carbon, 52.64; hydrogen, 6.95; nitrogen, 17.25; sulphur, 0.50; oxygen, 22.66. Besides vigin, the cow pea contains a globulin having the composition and—so far as could be determined—the properties of phaseolin, which occurs in the kidney bean (*Phaseolus vulgaris*), and the adzuki bean (*P. radiatus*).

The cow pea contains also a third globulin, soluble in very dilute salt solutions, which could only be partially precipitated by dialysis in water, but completely, in the coagulated form by dialysis in alcohol. This substance closely resembles in properties and composition, bodies obtained from several other leguminous seeds. On analysis this substance gave: carbon, 53.25; hydrogen, 7.07; nitrogen, 16.36; sulphur, 1.11; oxygen, 22.21 per cent.

—J. L. B.

*Adzuki Bean, Proteid of the White Poddled (Phaseolus Radiatus).* T. Osborne and F. Campbell. J. Amer. Chem. Soc. 1897, **19**, 509—513.

By treating the meal of this bean with 10 per cent. sodium chloride solution, and saturating the extract with ammonium sulphate, the authors have isolated a globulin, the sodium chloride solution of which, on dilution with water, and dialysis, yielded three fractions. The analysis of these preparations showed that fractional precipitation had brought about no separation, and that the globulin is identical in composition with phaseolin derived from the white bean (*P. vulgaris*). The phaseolin from adzuki bean was found to contain carbon, 52.56; hydrogen, 6.97; nitrogen, 16.45; sulphur, 0.57; oxygen, 23.45 per cent. The reactions of this globulin are identical with those of the phaseolin from the white bean.

Another proteid not precipitated by ammonium sulphate was obtained; it had the composition: carbon, 53.97; hydrogen, 7.01; nitrogen, 16.31; sulphur, 0.88; oxygen, 21.83. Proteids of similar composition, and obtained in a like manner, are found in the pea, vetch, and cow pea, and the authors believe that there is evidence of a distinct globulin which can only partly be removed from its solution by dialysis in water, but is wholly separated in a coagulated form by dialysis in alcohol.—J. L. B.

*Sunflower Seed, The Proteids of the.* T. B. Osborne and G. F. Campbell. J. Amer. Chem. Soc. 1897, **19**, 487—494.

RITTHAUSEN (Pflüger's Archiv, 1880, **21**, 89) found that by extracting sunflower meal free from oil, with very dilute alkali a proteid was obtained which, according to the authors, closely resembles the globulin edestin (this Journal, 1896, 665). By extracting sunflower meal in a Squibbs percolator with alcohol of 0.820 sp. gr., an acid was isolated, which the authors affirm to be helianthotannic acid. The meal residue was air-dried, and treated with 10 per cent. sodium chloride solution. The filtered extract was saturated with ammonium sulphate, and from the precipitated proteid a substance was obtained which, on analysis, gave the numbers: carbon, 51.54; hydrogen, 6.99; nitrogen, 18.58; sulphur, 1.00; oxygen, 21.71. This preparation, both in composition and in its behaviour towards reagents, resembles edestin, and it is concluded that this is the principal proteid present in the seed.—J. L. B.

*Globulin, Effect of Minute Quantities of Acid on the Solubility of, in Salt Solutions.* T. B. Osborne and G. F. Campbell. J. Amer. Chem. Soc. 1897, **19**, 482—487.

THE authors have obtained a globulin from the castor seed, part of which was soluble and part insoluble in a solution of sodium chloride. By further treatment of the soluble portion with brine, two fractions were obtained, the one not precipitated by saturation with salt, the other insoluble in saturated brine. Two fractions were also derived from the portion of the original globulin, insoluble in 10 per cent. solution of sodium chloride. These four fractions had practically the same composition, but behaved differently towards certain reagents. When treated with a quantity of acid too small to be detected with litmus or by analysis, changes were produced in the fractions soluble in saturated salt solutions; and products resulted having the same general properties as those exhibited by the fractions insoluble in saturated brine. Similar results were obtained by acting on edestin—the proteid of the hemp seed—with very small quantities of acetic acid. The same change apparently takes place by keeping the proteid for a long time in a dry condition.

It is evident that this change to a condition in which the globulin is precipitated by salt, is an intermediate step towards the development of the insoluble form—the so-called "albuminate" of Weyl; and the authors note that by treatment with warm common salt solution the insoluble matter can be changed into the form soluble in cold salt solution, and precipitable by saturation with common salt.

Attention is drawn to the fact that the only animal globulin obtained from an acid tissue is myosin, and that this substance is not only readily precipitated by saturating with salt, but that it quickly and spontaneously changes to the insoluble form, known as syntonin.—J. L. B.

## (B.)—SANITATION; WATER PURIFICATION.

*Arsenical Poisoning by Wall Papers, The Cause of.* T. Holas. J. Soc. Arts, **45**, 1897, 1101.

It has long been recognised that arsenical wall papers do serious mischief, but the work of Gosio and of Emmerling seems to have cleared up that mystery which has surrounded the matter. Certain moulds, including the very common *muco mucedo*, have a remarkable property of decomposing arsenical compounds, with the evolution of volatile products containing arsenic, and the highly poisonous character of

volatile arsenical compounds, coming into the system by way of the respiratory organs, is well known. Arsenious acid is, even in small quantities, a highly antiseptic substance and poisonous to moulds: so the throwing off of the arsenic in a volatile form may be an effort of nature to cast out the poison. The arsenical copper greens, and other colouring matters containing arsenic, are still used, and, paradoxical as it may appear, it is by no means improbable that the most dangerous wall papers are those containing a mere trace of arsenic, since when the quantity is large the moulds cannot exist. Traces of arsenic may come into wall papers from the imperfect washing of vessels used to contain the more highly arsenical colours. Now that boracic acid is very cheap, the old and perhaps forgotten suggestion of Bolley to use a precipitated borate of copper as a green pigment in place of the arsenical green deserves attention. Bolley's green is prepared by taking two parts of blue vitriol (crystallised cupric sulphate) and three parts of borax in separate quantities of cold water and mixing; after which the precipitate is washed and dried. Dyed and printed fabrics now very frequently contain traces of arsenic.

**Waste Acid from Metal Works.** Public Health Engineer, Oct. 2, 1897, 415.

See under X., page 801.

#### PATENTS.

**Filtering Apparatus [Water].** W. Defries, 4, Danes Inn, Strand, London. Eng. Pat. 19,039, Aug. 28, 1896.

THE filter is provided or connected with an air-tight chamber for the filtered water, and with a pump arranged to exhaust air and draw water from the chamber. The pump lever may be arranged to also work a second pump to supply water to the filter, &c., a ball-cock being employed to regulate the supply.—R. A.

**Filtering Liquids [Water], Impts. in and connected with Apparatus for.** W. Reeves and The Reeves Patent Filters Co., Ltd., both of 39, Victoria Street, Westminster. Eng. Pat. 21,805, Oct. 2, 1896.

THE filter can be divided into an upper and a lower chamber (the latter containing the filtering medium) by means of a removable water-tight division or valve. When it is necessary to cleanse the filter, the valve is closed, and the upper chamber is filled with water, which passes through a valve-controlled pipe to the bottom of the lower chamber, then upward through the filtering medium, and is discharged through an overflow pipe at the top of the lower chamber.

—R. A.

**Tobacco, or of the Smoke therefrom, for the purpose of Increasing its Salubrious Effect on the Smoker, and in means therefor: Impts. in the Treatment of.** E. T. C. Weiher, Romford, Essex. Eng. Pat. 22,192, Oct. 6, 1896.

THE tobacco, the paper for making cigarettes, or a porous plug for inserting in a pipe, is sprayed with a mixture, in stated proportions, of the following ingredients: benzoic acid, tannic acid, essences of cinnamon, myrrh, juniper, aniseed, and elder flower; benzoin and spirits of wine. In the case of the plugs, borax and alum are first added thereto.—R. S.

**Tanks and Filters for Precipitation and Filtration Purposes, and in the Appliances and Fittings arranged for use in the same: Impts. in the Construction of.** H. L. Himmell, Manchester. Eng. Pat. 22,503, Oct. 10, 1896.

THE tank described is oblong in shape and divided into compartments by transverse weir walls. Attached to each weir wall by brackets is a vertical scum plate, which dips below the surface of the liquid and keeps back floating matters. The sewage enters the first compartment from a distributing trough (which extends from side to side, and is provided with openings at intervals), flows from compartment to compartment under the scum plates and over the weir walls, and has its exit through a channel containing a strainer formed of parallel bars or plates, on which filter cloth may be stretched.—L. A.

**Filters, Impts. in [Water], and in Materials or Compositions for Filtering.** G. S. Marris, Islington Stamping Works, Ladywood, Birmingham, and W. J. George, 39, Cambridge Street, Birmingham. Eng. Pat. 21,051, Oct. 28, 1896.

IS a filter having the filtering material in the form of a thin disc, the disc is secured to the tubular opening between the upper and lower chambers of the filter by means of a flanged ring fixed by a bayonet joint, &c.; or, when the disc is of large size, it is supported and clamped on a flange and cross-bar by a perforated disc pressed down by a screw nut. The discs are made of an intimate mixture of cellulose or woody fibre, and animal or vegetable charcoal in fine powder, the mixture being treated by processes similar to those used in the manufacture of porous or unsized paper. The filtering material is thus obtained in the form of a tissue, which is preferably covered on both sides with unsized paper, and cut into discs.—R. A.

**Purification of Water in Open Vessels, Impts. in Means for.** A. Dervaux, 17, Rue Faidherbe, Lille, France. Eng. Pat. 6511, March 12, 1897.

FOR purifying water containing bicarbonate of lime, the water is passed through an upright vessel so as to form a downward current, and steam is led into the water at the bottom of the current so as to pass upwards through the same, the supply of water or steam being regulated so that the steam condenses before reaching the upper end of the column of water in the vessel. In the apparatus described the regulation is effected by a float or areometer, placed within the vessel and connected to the water- or steam-supply-cock.—R. A.

#### (C).—DISINFECTANTS.

##### PATENTS.

**Formic Aldehyde Vapours, Impts. in the Production of.** J. J. A. Trillat, Paris. Eng. Pat. 19,711, Feb. 5, 1896. (Under Internat. Convention.)

INSTEAD of directly transforming methyl alcohol into formic aldehyde by means of the apparatus described in Eng. Pat. 17,177 (this Journal, 1897, 695), the same apparatus may be used to vaporise formalin solution or to project it in a fine state of division into the air. To vaporise the solution, a rapid current of steam, carbonic acid, or compressed air may be employed, and a mineral salt, e.g. calcium chloride, may be dissolved in the solution, thus allowing it to be heated above 100° C. For spraying the solution, any of the means already in use for the treatment of vines by copper solution may be utilised. The vapours are preferably warmed in any suitable way, and then scattered into the atmosphere to be disinfected, by means of a revolving fan.—L. A.

**Aromatic Fluoro Compounds, A Process for the Production of.** F. Valentiner, Leipzig, Germany. Eng. Pat. 9827, April 17, 1897.

AS an example of the method employed, the patentee gives the following details:—10 kilos. of phenetidine, dissolved in 22 kilos. of hydrochloric acid and 20 litres of water, are diazotised with 5.11 kilos. of sodium nitrite, and the resulting diazo chloride solution is decomposed with 30 kilos. of hydrofluoric acid. After separating the oil, it is distilled with steam and fractionated. The pure product is a yellow liquid smelling pleasantly of aniseed. It melts at 17° C. and boils at 197° C.—T. A. L.

**Disinfection by Means of Formaldehyde, Impts. in or relating to.** W. Loebinger, Berlin. Eng. Pat. 17,464, July 24, 1897.

Porous plates of plaster of Paris or earthenware are soaked in formaldehyde solution and suspended in the space to be disinfected, or the solution may be placed in porous flasks similarly suspended.—L. A.

# XIX.—PAPER, PASTEBOARD, Etc.

## PATENT.

*Waterproof Paper, Fabric, and the like: A Process for the Manufacture of.* A. Scheufelen, Oberleuninggen, Wurtemberg, Germany. Eng. Pat. 11,795, May 12, 1897.

THERE is claimed "the process of manufacturing waterproof paper, fabric, and the like, consisting in fixing compounds of casein on the fibres by means of formic aldehyde."

# XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Molybdic Anhydride, Reduction of, by Hydrogen, and the Preparation of Pure Molybdenum.* M. Guichard. Comptes Rend. 1897, 125, 105—106.

MOLYBDENUM dioxide, heated in a current of hydrogen, begins to lose oxygen at about 500°, but the reduction is very slow; at 550° the reduction is very distinct, and at about 600° the metallic state is reached in a few hours; no intermediate oxide is produced. Molybdic anhydride,  $\text{MoO}_3$ , is completely reduced to the metallic state in about  $3\frac{1}{2}$  hours. An oxide of the formula  $\text{Mo}_2\text{O}_3$  is not produced, and where the reduction is incomplete, the product is a mixture of dioxide and metal. In fact, there appear to be only two anhydrous oxides of molybdenum, namely,  $\text{MoO}_3$  and  $\text{Mo}_2\text{O}_3$ .—A. K. M.

*Cerium, The Purification of.* Wyrouboff and A. Verneuil. Rev. de Chim. Ind. 1897, 8, [91], 210—212.

CERIUM differs from its allied metals in having a higher oxide,  $\text{Ce}_2\text{O}_3$ , which readily forms basic salts. On this depends Mosander's method of purification—treatment with chlorine in presence of alkali—as also Debray's method of fusion with nitre. The authors consider that both these methods, which are usually considered the most satisfactory ones, are not calculated to readily yield pure cerium; for, they point out, there exists an intermediate oxide,  $\text{Ce}_2\text{O}_3$  ( $=\text{Ce}_2\text{O}_3 \cdot 3\text{CeO}$ ), which is very stable, and also forms basic salts, and that in presence of lanthanum and didymium, more basic than cerium, a still more stable complex oxide is produced of the type  $\text{Ce}_2\text{O}_3 \cdot 3\text{MO}$ , in which  $\text{M} = \text{Ce} + \text{La} + \text{Di}$ . Thus, in Mosander's method, the prolonged action of chlorine does not prevent the formation of the intermediate complex oxide, whilst in Debray's process it is produced on the first application of heat.

After studying the conditions under which the intermediate oxide splits up into the constituents  $\text{Ce}_2\text{O}_3$ , forming basic insoluble salts, and  $\text{CeO} + \text{LaO} + \text{DiO}$ , giving neutral soluble salts, the authors have worked out the following method of purification:—The oxides left on moderately igniting the mixed oxalates are dissolved in hot nitric acid, which causes partial reduction, and formation of the intermediate oxide. The liquid is evaporated to syrupy consistence, dissolved in water, and ammonium nitrate (to 5 per cent.) added to the hot solution. The intermediate oxide is immediately dissociated, the oxide  $\text{Ce}_2\text{O}_3$  being precipitated as the basic salt  $(\text{Ce}_2\text{O}_3)_2\text{N}_2\text{O}_3$ , whilst the protoxides remain in solution. When washed with a 5 per cent. solution of ammonium nitrate, the precipitate is quite free from didymia, lanthana, and yttria. The remainder of the cerium (25 per cent.) can be recovered by adding oxalic acid to the filtrate, igniting the oxalates, and repeating the above process.

When the mixed oxides contain more than 50 per cent. of ceria, the oxalates should be dissolved in nitric acid, and hydrogen peroxide and ammonia added. The brown peroxide is transformed into the yellow ceroso-ceric hydroxide by boiling, and this, when washed, is dissolved in nitric acid and the purification carried out as before. The precipitate is still impure, as the whole of any thorium present in the original oxides is simultaneously thrown down. The cerium obtained from the filtrate, however, is quite free from it, and in any case it may be removed by a preliminary treatment of the oxalates or nitrates, as neutral as possible, with a con-

centrated solution of ammonium carbonate containing ammonia, which readily dissolves the thorium salt. Two treatments remove all but about 1 per cent., and this may be separated by crystallising the sulphates from a solution not containing free sulphuric acid, when the thorium sulphate accumulates in the mother-liquor, forming with cerium an exceedingly soluble double sulphate. Iron is removed by precipitating cerium nitrate or chloride from hot acid solution with oxalic acid; or by dehydrating the sulphate at 400—450°, which leaves the iron in an insoluble state.—C. A. M.

*Ammonio-Citrate of Bismuth, Examination of Trade Samples of.* W. G. Stratton. Brit. Pharm. Conf. (through Pharm. J. 1897, 59, 157).

THE examination of 11 samples of the official *Liquor Bismuthi et Ammonii citratis* derived from different sources, showed that great variation existed among them, notably in the amount of ammonia and of citric acid, as shown in the following table:—

—	Sp. Gr.	Per Cent. Bi.	Per Cent. $\text{NH}_3$	Per Cent. $\text{C}_6\text{H}_5\text{O}_7$	Impurities.
Theoretical	1.070	4.375	..	3.956	
1	1.070	4.377	1.048	3.910	Nitrates
2	1.063	4.167	0.927	3.427	
3	1.135	4.476	3.535	14.209	..
4	1.070	4.748	0.746	3.647	
5	1.073	4.585	0.807	4.109	
6	1.073	4.548	0.871	3.817	
7	1.072	4.285	0.991	4.232	..
8	1.150	5.552	3.777	14.736	..
9	1.070	2.968	2.034	6.126	..
10	1.122	5.164	3.200	11.426	..
11	1.020	1.944	0.686	2.663	..

The large excess of ammonium citrate is probably added in some cases to render the solution more stable.—J. O. B.

*Menthol Carbonate, Preparation of.* H. Erdmann. J. für prakt. Chem. 1897, [13] and [14], 43.

THE pyridine method is stated to be very suitable for the preparation of menthol carbonate. 30 grms. of menthol are dissolved in 30 c.c. of chloroform, and 25 c.c. of anhydrous pyridine added. The mixture is cooled by means of a freezing mixture, and 55 c.c. of a chloroformic solution of phosgene (containing 10 grms. of phosgene) slowly added with occasional shaking. After standing one day in the cold, the whole is steamed, thus getting rid of the pyridine and traces of unchanged menthol. In the residue is obtained a nearly quantitative yield of crystalline menthol carbonate, which is washed with hot water and dissolved in a large quantity of hot alcohol. The menthol carbonate, being only slightly soluble in alcohol, separates out on cooling, in the form of long, white prisms, with a constant melting point of 105° C.—A. S.

*Tropeines of the Triacetone-amine Series.* C. Harries. Annalen, 296, 328—343.

$\alpha$ -VINYLDIACETONAMINE yields—on methylation, extraction with ether, and treatment with alkali, and subsequently with mandelic acid—a tropeine without physiological action on the eye.

The corresponding compound of  $\beta$ -vinyl diacetonealkamine is prepared in a similar manner; the methylation is carried out as in the case of the  $\alpha$ -compound, but the methylated base is easily purified, distillation of the petroleum ether extract being sufficient to obtain it in crystalline scales. The aqueous solution is strongly alkaline; the base forms a crystalline hydrochloride, eldoroaurate and platinate. Conversion into the tropeine takes place more rapidly than with the  $\alpha$ -compound. The oil separated by sodium carbonate, crystallises, and is purified by recrystallisation from boiling petroleum ether. So prepared, the tropeine forms small hexagonal prisms, which sinter at 108° and melt at 113°, and are almost insoluble in cold water.

The alkaloid placed on the pupil of the eye causes dilation; the maximum effect in man is observed after 40 minutes, and disappears after about an hour and a half.

—A. C. W.

**Rhodinol,  $C_{10}H_{17}$ , Oil; Preparation and Properties of the Pure.** H. Erdmann and E. Erdmann. J. Prakt. Chem. 1897, **56**, 1-5.

RHODINOLDIPHENYLURETHANE is a well crystallised compound (H. Erdmann and Huth, this Journal, 1896, 292) melting at  $82^{\circ}$  (not at  $84^{\circ}$ , loc. cit.). It is, however, not possible to prepare pure rhodinol from this substance, the diphenylamine formed in its decomposition being very difficult to remove. Pure rhodinol was obtained by the addition of sodium chloride to rhodinolphthalate of silver,  $C_{10}H_{17}O.CO.C_6H_4.CO.OAg$ , and decomposition of the resulting sodium salt by alkali. It is a liquid with a very pleasant smell of roses; it cannot be distilled under ordinary pressure without injury to its odour; under 16 mm. pressure it boils at  $110^{\circ}5-111^{\circ}$ . The specific gravity at  $16^{\circ}$  is 0.8812, referred to water at  $4^{\circ}$ . Warm rhodinol dissolves lithium and calcium chlorides; the compound with the latter salt crystallises, but cannot be used for the isolation of the alcohol, because impurities readily prevent its crystallisation, and when decomposed by water, chlorine compounds are formed.

If one drop of rhodinol be diluted with 5 c.c. of alcohol, and 10 drops of concentrated sulphuric acid added without shaking, the acid sinks, and takes an intense orange-yellow colour; on gently moving the vessel, the colour turns to reddish-violet at the surface of contact of the liquids. Linalool shows a similar reaction, the colour being less stable, and rapidly turning brown. Citronellol gives a feebler coloration of a bluish tint.—A. C. W.

**Rhodinol,  $C_{10}H_{17}$ , Oil; Occurrence and Detection of, in Essential Oils.** H. Erdmann and P. Huth. J. Prakt. Chem. 1897, **56**, 27-42.

THE smell, boiling point, and the sulphuric acid test (see preceding abstract) indicate the probable presence of rhodinol in an essential oil. 1 grm. of oil is heated on the boiling-water bath for 2 hours with 1.5 grm. of diphenylcarbamine chloride and 1.35 grm. of pyridine; the mixture is distilled with steam, and after about 1 litre of water has passed over, the residue, which solidifies on cooling, is crystallised from 30 times its weight of alcohol. In the presence of much citronellol it is more difficult to isolate pure rhodinoldiphenylurethane; crystals are obtained melting between  $40^{\circ}$  and  $50^{\circ}C$ , and apparently a molecular compound of the urethanes of the two alcohols. Only after repeated recrystallisation is the rhodinol compound obtained of the right melting point,  $82^{\circ}C$ . Under these circumstances it is of advantage to cool the alcoholic solution of the urethane to  $20^{\circ}$ . If sufficient quantities of a natural oil are under investigation, it is better to distil, and subject the fraction coming over at the boiling point of rhodinol to the treatment with diphenylcarbamine chloride and pyridine. If the oil contain no rhodinol, diphenylamine passes over with the steam as an oil, which soon solidifies. Unaltered carbamine chloride is not found in the residue after steam-distillation. Rhodinol was found in the following essential oils: Turkish and German rose oils, French, Réunion and Syrian geranium oils, ginger grass oil, oil of lemons, Turkish palmarosa oil, oil of Néroli bigarade, and Portuguese oil of Néroli. The yields were very different: the Néroli oils contain very little free rhodinol; 5 grms. of Turkish rose oil, on the contrary, gave 8.3 grms. of crude urethane, which, on recrystallisation, became 4.4 grms. of almost pure rhodinoldiphenylurethane. The rose oils, when not previously fractionated, showed a peculiar behaviour; very little passes over with the steam, but the urethane has a very low melting point and great solubility; this is not entirely due to the presence of citronellol, which these oils only contain in small quantity. Perhaps they contain a third alcohol which is capable of forming a crystalline urethane.

—A. C. W.

**Tertiary *p*-Butyltoluene [Artificial Musk] and its Nitro Derivatives.** M. Białobrzęski. Ber. 1897, **30**, [13], 1773-1776.

ACCORDING to the researches of Baur (this Journal, 1891, 1024, and 1894, 1218), the same tertiary butyltoluene,  $C_6H_4(CH_3).C(CH_3)_3$ , is obtained by the action of aluminium

chloride and toluene on isobutylchloride, isobutylbromide, and tertiary butylbromide. By the oxidation of this hydrocarbon (in which the butyl group occupies the meta position) with dilute nitric acid, Baur obtained *m*-butylbenzoic acid and isophthalic acid. The trinitro derivative of *m*-butyltoluene, as is well known, is the artificial musk.

By substituting ferric chloride for aluminium chloride, the author has obtained, by the action of toluene on tertiary butylchloride and isobutylchloride, a butyltoluene (b. pt.  $189^{\circ}$ —190, sp. gr. 0.8784 at  $0^{\circ}$ , 0.8611 at  $23^{\circ}$ ), which refuses to be nitrated beyond the dimtro stage—

The suspicion that the butyltoluene thus prepared was not identical with the *m*-butyltoluene obtained by Baur, was confirmed by oxidising it with chromic acid, when *p*-butylbenzoic acid of melting point  $164^{\circ}$  was formed, and this, on being heated with dilute nitric acid in a sealed tube, was converted into terephthalic acid. It therefore follows that by the action of toluene on tertiary butylchloride, *m*-butyltoluene is formed in the presence of aluminium chloride, whilst *p*-butyltoluene is formed in the presence of ferric chloride. And since in the latter hydrocarbon the para position is already occupied, it is impossible to introduce more than two nitro groups, or to prepare artificial musk from it.—J. S.

**"Dulcine," or Paraphenyltol Carbamide.** R. Raggeri. Ann. del. Lab. Chim. Centr. delle Gabelle, III., 138.

**Carbon Bisdiphide, Estimation of, in Alcohol, Carbon Tetrachloride, &c. Purification of Commercial Carbon Tetrachloride, and a New Reaction for the same.** W. Schmitz-Dumont. Chem. Zeit. 1897, **21**, [50], 487 and 516.

See under XXIII., page 829.

## PATENTS.

**Condensation Product [Anti-neuralgic] from Vanillin and *p*-Phenetidine, Preparation of.** C. Goldschmidt, Frankfurt-on-Maine, Germany. Eng. Pat. 14,954, July 6, 1896.

THE preparation of a condensation product—

by heating vanillin with *p*-phenetidine at  $140^{\circ}C$ , is claimed. The product melts at  $97^{\circ}C$ , dissolves in cold water, is only slightly poisonous, and exerts, it is claimed, an anti-neuralgic and soporific action.—A. C. W.

**Hair Lotions, A New or Improved Manufacture of.** J. Herbst, Munchelberg, Germany. Eng. Pat. 17421, Aug. 6, 1896.

THE constituents of the lotions claimed, are, a solution of quinine in benzene, tincture of cantharides, balsam of Peru, gum benzoin, castor oil, and alcohol.—A. C. W.

**Oxy-Camphor, Improved Manufacture of.** O. Imray, London. Farbwerke vorm. Meister Lucius and Brüning, Höchst a/Main, Germany. Eng. Pat. 18,035, Aug. 14, 1896.

THE manufacture of an oxy-camphor—

by reduction of camphor quinone in acid, neutral, or alkaline solution, is claimed. The substance melts at  $203^{\circ}$ — $205^{\circ}C$ , and is tolerably soluble in water.—A. C. W.

**Oxygen, Extracting, from the Air; Process and Apparatus for.** A. F. de Villepigue, Rue de la Victoire, Paris; V. Fourrier, Rue Caumartin, Paris, and G. Shenton, Copthall House, Copthall Avenue, London. Eng. Pat. 19,044, Aug. 28, 1896.

THE air is dialysed through a series of "membranes of tissue" treated with caoutchouc, the proportion of oxygen in the air being increased by the consecutive passages of the air

through the membranes, until it becomes sufficiently pure for practical purposes. The apparatus employed, consists of a spoked wheel mounted on a tubular arbor, the centre of which communicates with one of the hollow spokes of the wheel; a series of bellows arranged round the periphery of the wheel, the fixed walls of these bellows being constructed of "a membrane of tissue" treated with caoutchouc, and so arranged that one of the bellows communicates with the above-mentioned hollow spoke, and the following bellows communicates with the atmosphere, the bellows being connected one with the other by convenient tubes. Two drums are mounted over the wheel, against the periphery of which they press in order to consecutively compress the bellows.

—R. A.

concentrated sulphuric acid, and then with the same substance, or its mixture with ethyl sulphuric acid, at 100°—140° C.

Each of four vessels, A, B, C, and D, is charged with the ethyl sulphuric acid, the contents of A being diluted with 35 per cent., of B with 22 per cent., and of C with 10 per cent. of water, whilst the acid in D is undiluted. The vapours of alcohol, ether, and water pass from each vessel into the one above; ether and water alone are evolved from D; these are condensed. The process is continuous, a current of acid flowing down the series, diluted in A, B, and C by a constant stream of water. The vessels may be heated, as by a steam coil in each vessel having its inlet and outlet *St*. This process is claimed as described.—A. C. W.

**Acetosulphanilate Salts [Antipyretics], Manufacture of Pure.** F. Hoffmann, La Roche and Co., Basle, Switzerland. Eng. Pat. 29,417, Dec. 22, 1896.

The patent claims the alkaline acetosulphanilates and the process for their manufacture, which consists in boiling sodium sulphanilate with glacial acetic acid, distilling off excess of acid, dissolving in a little water, filtering from sulphanilic acid, precipitating and washing with strong alcohol.—A. C. W.

**Thorium Oxide, New or Improved Process for Obtaining, and for Enriching Monazite Sands.** W. Buddens, Berlin, Germany. Eng. Pat. 9996, April 21, 1897.

The process, the various stages and modifications of which are described in the 12 claims, is substantially as follows:—The sand, crushed to such a fineness that the grains are  $\frac{1}{2}$  mm. in diameter, is introduced into molten potash or soda at 400°—500° C.; water is added, dissolving the alkaline phosphate and excess of hydrate. The washed residue is made somewhat alkaline and stirred with water; the lighter oxides are suspended and washed away from

**Ether from Gases containing Ethylene, Obtaining, and Apparatus therefor.** P. Fritzsche, Essen, Germany. Eng. Pat. 20,225, Sept. 12, 1896.

When gases containing ethylene—purified coal-gas, coke-oven gases or oil-gases—are passed through a series of wash bottles containing concentrated sulphuric acid, the hydrocarbons of high molecular weight are mainly absorbed in the first bottle, and their absorption hinders that of ethylene. Moreover, ethylene combines slowly with sulphuric acid at ordinary temperatures, the most favourable temperature is 110°—120°, at which the decomposition of the resulting ethylsulphuric acid is slight. The patentee claims the method for obtaining ethylsulphuric acid, which consists in treating gases containing ethylene with cold

ferrous titanate and zircon. These oxides are allowed to settle, and treated with an acid (sulphurous acid), which will dissolve the greater part of the ceria, leaving all the thoria.—A. C. W.

**Tribenzoyl-gallic Acid, Process for the Production of.** L. Landshoff and P. Meyer, Grünau, Germany. Eng. Pat. 10,041, April 22, 1897.

The claim is for the process, which consists in shaking an alkaline solution of gallic acid with benzoylchloride, boiling with water, and purification by recrystallisation. Tribenzoyl-gallic acid is insoluble in water, fairly soluble in hot alcohol, less in cold; is not decomposed by exposure to air or treatment with water.—A. C. W.

**Alkoxyated Phenols, A Process for the Production of Indifferent (Neutral) Compounds of.** L. Lederer, Munich, Germany. Eng. Pat. 12,963, May 25, 1897.

The patentee claims the process for the production of neutral esters of alkoxyated phenols, which consists in causing alkoxyated phenols in the presence of potassium carbonate or their compounds with potassium carbonate (this Journal, 1897, 758) to react with phosgene, chloro-carbonic esters, acid chlorides, &c. By the introduction of radicals, so as to neutralise the OH group, in the alkoxyated phenols, it is said, "their therapeutic usefulness is increased."—A. C. W.

**Ointment, Unguent, or Salve, A New.** J. C. Mewburn, London. From The Chemische Fabrik von Hayden Gesellschaft mit beschränkter Haftung, Radebeul, near Dresden, Germany. Eng. Pat. 16,869, July 16, 1897.

The claim is for "an ointment, unguent, or salve of which the characteristic feature or element is a soluble form or modification of silver in the proportion of 1 to 30 per cent. of the silver to 70 to 99 per cent. of a suitable grease or carrier."—C. A. M.

*Therapeutical Compounds [Bismuth Oxiodide and Tannin], Manufacture of New.* Society of Chemical Industry in Basle, Switzerland. Eng. Pat. 17,402, July 23, 1897.

IN this patent are claimed compounds of bismuth oxyiodide with tannin, another tannic acid or a compound of formic aldehyde with tannin, and the process for obtaining these substances, which consists in dissolving one or two molecules of a bismuth salt in dilute acid, adding sodium acetate and a solution of one molecule of tannin and one or two molecules of potassium iodide, and treating the precipitate with sodium bicarbonate.—A. C. W.

## XXI.—PHOTOGRAPHY.

*Photographic Plates, Action of Metals and other Substances on.* W. J. Russell. Proc. Roy. Soc. 1897, 61, 424—433.

Zinc, laid on a photographic plate in the dark for a week or more, acts on the plate so that, when developed, a dark picture of the zinc is obtained. The metal must be clean, and if it be rubbed with coarse sand-paper the picture shows every scratch made. Other metals produce similar results, mercury being the most active, while magnesium, cadmium, zinc, nickel, aluminium, pewter, fusible metal, lead, bismuth, tin, cobalt, antimony, follow in order. Moisture has no influence on these results, but the action is much stronger and more rapid at high than at low temperatures. Other bodies were also found to produce these results—copal varnish, in a high degree, wood of various kinds, charcoal, printing ink of some kinds, strawboard, and certain brown papers. Among liquids, methylated spirit, turpentine, and oil of cloves gave slight effect; other liquids tried were without action.

Contact is not necessary for the production of these effects; and the action will take place, not only through air, but through screens of various materials, such as celluloid, gelatin, gutta-percha tissues, collodion, parchment and vegetable parchment, gold-beaters' skin, tracing paper, &c. Glass, however, is opaque to the action, and different writing papers show great differences in regard to it. Gelatin may be coloured, or paper may be painted with colours or with Indian ink, without any effect on their transmissive powers.

Further experiments are in progress with the view of discovering the cause of these phenomena.—J. T. D.

*Silver in Silver-plating Solutions, Estimation of.* T. J. Baker. Chem. News, 1897, 76, 167.

See under XXIII., page 828.

## PATENTS.

*Ornamenting Objects of Metal, Porcelain, or the like by Photography: A Process for.* T. Häusermann, Vienna. Eng. Pat. 14,927, July 6, 1896.

THE patent claims "a process for ornamenting objects of metal or porcelain in colours from brown to black, consisting in coating such objects with chrome glue, then exposing the same to light by the aid of a negative or template pattern, and, after washing, heating to 300—400° C."—A. C. W.

*Permanent Photographs on China and other Vitreous Surfaces, A New or Improved Method or Process of Producing.* J. Slater, Burslem. Eng. Pat. 21,681, Sept. 23, 1896.

A GLASS plate is coated with nitrocellulose, 100 grains, alcohol, 2½ oz., and ether, 10 oz.; and sensitised in gum arabic, 100 grains; sugar, 60; potassium bichromate, 80 grains; methylated spirit, 1 oz.; and water, 7 oz. It is exposed under a positive, dusted over with enamel colours "in accordance with the lights and shades or natural colouring of the object photographed," washed till free from bichromate, stripped from the support, and laid on the plaque. This is fired as usual, then painted and again fired, and a second film, prepared and dusted exactly as before, superimposed on the image, and burnt a third time. Additional

films can be adjusted on the enamel and also burnt in, if so desired. It is claimed that the pictures possess a more life-like tone and a better finish than such as are produced in the ordinary manner.—F. H. L.

*Hypsulphites [Thiosulphates], New or Improved Process for removing from Photographs Negatives and Prints.* P. Mercier, Paris. Eng. Pat. 12,482, May 20, 1897.

TO remove hypsulphites (thiosulphates) after fixing, this patent claims the use of solutions of alkaline bromides or iodides, with or without the addition of alkaline substances (sodium carbonate); also of an aqueous solution of bromine or iodine, mixed with an alkaline solution and decolorised by heating or other means.—A. C. W.

*Prints similar to Photographic Prints, An Improved Chemical Method of Producing.* H. Soar and J. W. Cooper, London. Eng. Pat. 13,751, June 4, 1897.

IN prints prepared by this process, the material of which the image is formed consists of a metal deposited by purely chemical means instead of by the action of light. This is effected by bringing together, under pressure, a damp sheet of paper containing a salt of some easily reducible metal (such as the gelatino-chloride "printing-out" papers of commerce), and a specially prepared metallic block (made of zinc, bronze, &c.) in which the shadows of the picture are represented by bare metal, whilst the lights are protected by a resist. In presence of the moisture, a reaction between the zinc and the salt of silver sets in, determining the precipitation of the latter metal in the pores of the paper. Other substances besides silver may also be employed, provided they will yield a coloured deposit: salts of gold, lead, nickel, or iron may either be introduced into the emulsion with which the paper is coated, or they may be added to the water with which it is damped.

The plate is prepared by any of the known photo-engraving methods, carrying the process up to the point where it is, in the ordinary way, ready for immersion in the acid bath. A block may also be produced in bichromated gelatin on a glass or similar non-metallic support, being developed in bronze or other metallic powder by "dusting-on." Or, a metallic plate may be coated with a resist and engraved or otherwise cut through mechanically, to give the necessary design.—F. H. L.

## XXII.—EXPLOSIVES, MATCHES, Etc.

### PATENTS.

*Explosive Compounds for Blasting Purposes, Impts. in.* J. C. Hamilton, Arnsdale, Lancaster. Eng. Pat. 22,162, Oct. 6, 1896.

OXALATE of urea (about 15 per cent.) is added to the explosive—either black gunpowder or nitroglycerin class; this addition is said to render these flameless, or reduce the amount of flame during combustion.—W. M.

*Denitrating Acid which has been used in the Nitroglycerin Manufacture, An Improved Process for.* G. Kynoch and Co., Ltd., and A. T. Cocking, Wlinton, Staffordshire. Eng. Pat. 22,718, Oct. 13, 1896.

IN this invention the waste acid is allowed to flow from a reservoir into a small vessel in which some hot water has been placed. The mixture of acid and water generates sufficient heat to start the decomposition of the nitrated bodies in the acid, and the heat is maintained by the decomposition of these bodies. The purified acid is allowed to flow out of the small vessel, the proper rate of in- and outflow being found by experiment.—W. M.

*Explosives, Improved Manufacture of.* M. Bielefeldt, Wittenburg, Saxony. Eng. Pat. 18,634, Aug. 14, 1896.

THE claim is for an explosive composed preferably in the following proportions: ammonium nitrate 100 parts, potassium nitrate 4·5 parts, and resin 5·5 parts, the ingredients of which have been intimately mixed and then heated until only the resin begins to melt.—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

## APPARATUS, ETC.

*Boiling-Point Apparatus, for Use with Low- and High-Boiling Solvents.* H. C. Jones, Amer. Chem. J. 19, 581—597.

The stopper is placed in the neck of A, the side-tube corked, and the vessel weighed; the solvent is put in (in quantity just enough to avoid boiling over from inside to outside of the platinum cylinder) and the whole re-weighed. The cork carrying the thermometer is substituted for the stopper, the vessel inserted in the jacket and pushed down till the bottom is in contact with the gauze, and connection made with the condenser. Heat is applied till the liquid boils, the flame regulated so as to secure active and regular boiling, and after sufficient time the thermometer read with a hand lens. The apparatus is allowed to cool somewhat, the substance to be investigated added from a weighed tube either through the condenser or by removing the thermometer, and the boiling point of the solution now determined.

The advantages of this apparatus, beyond its simplicity, and ease of construction and of manipulation, are, that it minimises the effect of radiation, prevents the condensed solvent from touching the thermometer till it has been reheated, and renders an outer vapour jacket unnecessary. The results obtained by it show that it meets all practical demands.—J. T. D.

*Motor, New Laboratory Water.* H. Tryller. Ber. 1897, 30, 1729—1731.

The author describes a new laboratory motor, which he claims can be more easily regulated, and which uses less water than the well known Kube motor. When working

at a low speed it produces no noise whatever, whilst at high speed it is free from vibrations, which are so apt to throw off the driving cord.

The construction of the motor may be gathered from the accompanying figures. A is a shallow cylinder 100 mm.

great resistance offered by the wire gauze B causes the disc to rotate.—J. S.

*Extraction Apparatus, A New.* E. Diepolder. Ber. 1897, 30, [13], 1797—1798.

The new extraction apparatus, which is an improved form of that devised by Schwarz (Zeits. Anal. Chem. 23, 369; this Journal, 1884, 648), is shown in the accompanying

Fig. I.

Fig. II.

Fig. III.

figure. The tall, narrow cylinder A, Fig. I., contains the liquid to be extracted, and has sealed into it the heat exit tube F, the longer limb of which must be so arranged as

not to act as a siphon. The surface of the liquid to be extracted must be quite free of the opening to F. The solvent is then poured into A, and when sufficient has run over into the flask B the open end of A is closed by means of a split cork. When B is heated, the vapour of the solvent rises up through D, is condensed in the spherical Soxhlet's condenser, and passes down through E. When the hydrostatic pressure of the condensed solvent in the central tube becomes sufficiently great, the solvent passes up through the liquid, extracting the soluble matter on the way, and flows over into the flask B.

In order to distribute the solvent better, the lower end of the tube E may be provided with several small openings.

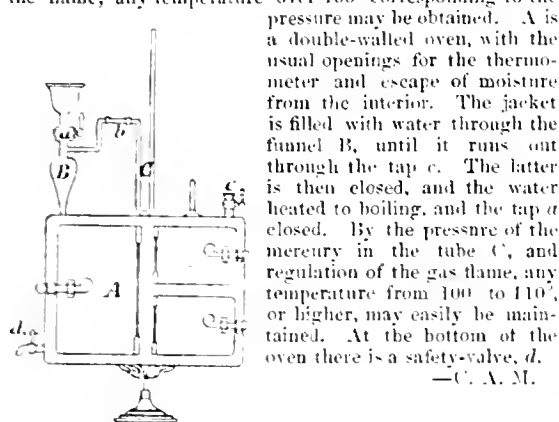

Fig. 11, represents a plan of the apparatus with the tube E in a central position, whilst in Fig. 111, it is shown at the side, with an upward bend at the lower end, in order to allow the use of a Witt's stirrer to facilitate the mixing of both liquids.

The apparatus as shown is for solvents which are specifically lighter than the liquid to be extracted. If denser solvents are employed, the tube F must be continued to the bottom of the vessel A, whilst E dips just under the surface of the liquid.

By heating or cooling the vessel A, the extraction may be conducted at any required temperature.—J. S.

*Hot-Water Oven, A New, for Temperatures over 100° C.*  
F. Gantter. *Forschungs. Ber.* 1897, 4, [6], 154—155.

The tube from which the steam escapes is connected with a barometer tube containing mercury, so that by regulating the flame, any temperature over 100° corresponding to the pressure may be obtained. A is a double-walled oven, with the usual openings for the thermometer and escape of moisture from the interior. The jacket is filled with water through the funnel B, until it runs out through the tap c. The latter is then closed, and the water heated to boiling, and the tap a closed. By the pressure of the mercury in the tube C, and regulation of the gas flame, any temperature from 100° to 110°, or higher, may easily be maintained. At the bottom of the oven there is a safety-valve, d.

### INORGANIC CHEMISTRY.— QUANTITATIVE.

*Copper Sulphide, Solubility of, in Fused Alkali Polysulphides.* E. Prost and A. van de Castele. *Bull. Assoc. Belge des Chim.* 11, [3], 99—102.

The summary of the experimental results detailed in this article is as follows:—

1. The amount of copper which can be converted into soluble sulpho salt by fusing a salt of copper with an alkaline carbonate and sulphur, increases rapidly with the proportion of flux used.

2. The action is more energetic when potassium carbonate is used instead of sodium carbonate in the flux (26 grms. of the latter, along with sulphur, converting 65.6 per cent. of 0.1 grm. of copper into a soluble sulpho salt, whereas 26 grms. of the former converted 98.2 per cent. of the 0.1 grm. of copper).

3. The quantity of copper converted into sulpho salt appears to be inversely proportional to the duration of the fusion, at least within certain limits. The maximum is in all cases quickly attained.

4. The presence in considerable proportion of a metal like tin, susceptible of being converted into a sulpho salt, appears to diminish the action of the alkaline sulphur flux on the copper.

5. Methods of separation in which copper is brought to the state of sulphide by fusion with alkali polysulphide, and subsequently determined after elimination by means of water of the sulpho salts of the metals of the sixth group, are to be regarded with suspicion. In certain cases under such conditions the qualitative detection of copper is not possible.—C. S.

*Tin, Analysis of.* E. Prost and A. van de Castele. *Bull. Assoc. Belge des Chim.* 11, [3], 103—112.

With the idea of reducing the complexity of the ordinary methods of analysing tin, and of estimating in the one sample the arsenic, antimony, lead, copper, bismuth, and iron present, the authors propose to utilise the fact applied by Clarke (*Chem. News*, 21, 124) in the estimation of tin, arsenic, and antimony in alloys, *viz.*, that if a solution containing these metals be treated with hydrogen sulphide in presence of oxalic acid, only the two last-named will be precipitated; copper and bismuth are also precipitated, but lead not completely.

The method consists in dissolving 30 grms. of tin at a gentle heat, in nitrohydrochloric acid, neutralising almost completely with potassium hydroxide and adding 130 grms. of oxalic acid in solution. After making up the volume of the liquid to about a litre, a current of hydrogen sulphide is passed for at least two hours, at a temperature of 70°—80° C. The brownish-black precipitate, containing all the arsenic, antimony, copper, and bismuth present, as well as a little tin and some of the lead, is washed and treated, at water-bath temperature, with sodium sulphide to remove the sulphides of arsenic, antimony, and (stannic) tin (solution S), the residue is washed with salt water to prevent it from escaping in the colloidal state, and is then dissolved in nitric acid (solution P).

The original filtrate, which must be kept concentrated and warm, to prevent the deposition of stannic sulphide, contains part of the lead in addition to the iron; it is now treated with potassium hydrate until the stannic hydrate first formed is dissolved. Under the influence of the heat, a white metastannic compound is also thrown down, and, after washing by decantation, may (1) be dissolved along with the iron by very dilute hydrochloric acid, leaving behind the lead sulphide (P<sup>1</sup>). The tin is thrown down from this solution by hydrogen sulphide, and the iron estimated in the filtrate. Another method (2) of dealing with the metastannic precipitate is to wash it with salt water on a filter and fuse it, after drying, with sodium carbonate and sulphur. On taking up the mass with water the sulphides of lead and iron are left and, after dissolving in nitric acid, are added to the solution P. This is then evaporated along with sulphuric acid to convert the lead into sulphate (contaminated slightly with tin). Bismuth and copper are thrown down from the filtrate by hydrogen sulphide, then purified from tin by means of sodium sulphide, re-dissolved in nitric acid, and estimated as sulphide and oxide respectively, or in any other way. Iron is estimated in the final filtrate. The residue from (1) is treated as above, except as regards the iron.

The solution S is decomposed by hydrochloric acid, the reprecipitated sulphides being filtered, washed, and flushed into a basin, dried on the water-bath, and the tin and antimony dissolved out by concentrated hydrochloric acid, leaving behind arsenic sulphide, from which, on solution in bromine water, the arsenic is precipitated in the usual manner as ammonio-magnesian arseniate, the filtrate being tested for antimony by hydrogen sulphide. The antimony is separated from tin in the above solution by nearly neutralising with KHO, then adding 10 grms. of oxalic acid and passing hydrogen sulphide. For checking the result, the precipitate may be dissolved in HCl and the antimony thrown down by a rod of tin in a platinum basin.

The tabulated results of analyses performed in the above manner on tin containing known quantities of the foreign metals in question, show that the method is accurate to within 0.001—0.005 per cent. (of total substance) in all cases except lead, where the amount escaping detection is somewhat higher, *viz.*, 0.008 to 0.013 per cent.—C. S.

*Silver in Silver-plating Solutions. Estimation of.*T. J. Baker. Chem. News, 1897, **76**, [1975], 167.

When estimating silver in residues, precautions must be taken to separate the copper cyanide and other impurities precipitated along with the silver chloride. To avoid this and also the formation of small globules of silver adhering to the crucible, when the impure silver chloride is fused with sodium carbonate and nitre, the following method is suggested:—Precipitate all the silver as cyanide, together with copper cyanide and other impurities, by boiling 50 c.c. of the solution with a slight excess of nitric acid. Wash and dry the precipitate, burn the filter-paper, and wrap up the ash together with the precipitate, in assay lead. Compress into a small bulk and cupel, employing the usual precautions of duplicate assays and checks. The method is said to give good results.—A. S.

*Electro-plating and Gilding Solutions, Note on the Assay of.* A. H. Allen. Chem. News, 1897, [1978], 199.

Is the article of which the above is an abstract, T. J. Baker appears to suggest that the existing methods of analysis for the assay of plating solutions are imperfect. The author gives a method, proposed by him some 20 years ago, which he thinks better than that described by Baker.

20—50 c.c. of the plating solution are largely diluted with water and the whole raised to boiling. Sulphuretted hydrogen is passed through or ammonium sulphide gradually added. The precipitate of silver sulphide, probably contaminated with copper and zinc, is filtered off, washed, and rinsed off the filter into a flask or beaker. It is then treated with an excess of bromine water, and if any sulphur appears to have separated, a drop of bromine should be added to ensure complete oxidation. Boiling water is then added, and the silver bromide filtered off, washed, dried, fused, and weighed. 188 parts by weight of the precipitate represent 100 of metallic silver.

For the determination of the precious metal contained in the solution of the double cyanide of gold and potassium used for electro-gilding, the following method is recommended:—A measured quantity of the solution is cautiously concentrated to a syrupy consistence, in a porcelain crucible. A few grms. of pure red lead or litharge are then added, and the evaporation continued to complete dryness. The crucible is covered and raised to a moderate red heat for a short time. The resulting button of metallic lead is separated from the slag, and the gold contained in it is separated either by cupellation or by treatment with pure nitric acid.

Electro-silvering solutions may be assayed in a precisely similar manner; but in this case the silver must be recovered by cupellation, since the nitric acid treatment is of course inadmissible.—A. S.

*Mineral Phosphates. Estimation of Lime, Alumina, and Iron in.* L. Lindet. Comptes Rend. **125**, [4], 245—247.

To avoid the inconveniences attendant on the usual methods of removing the citric acid from the ammoniacal liquid remaining after the precipitation of ammonio-magnesium phosphate, the author proposes to utilise Villiers' method of oxidising organic substances by nitric acid in presence of a manganese salt (Comptes Rend. **124**, 1349; see page 832). To this end, the liquid is saturated with nitric acid, and there are then added 0.5 grm. of manganese nitrate or sulphate, and about 50 c.c. of nitric acid per 20 grms. of citric acid, the mixture being gently warmed and nitric acid added at intervals, as the reaction slackens, until the evolution of gas ceases. The citric acid will thereby be decomposed, and iron and alumina may then be thrown down by ammonia, and separated from manganese in the usual manner.

Vanadyl dichloride, being more energetic, may be used in place of manganese salts, 0.1 grm. sufficing to oxidise 20 grms. of citric acid. The ammonium hypovanadate thrown down with the iron and alumina is insoluble under the conditions prevailing. In place of separating it from the two latter, the weight may be deducted from that of the calcined precipitate, to which end a 1 per cent. solution of

the dichloride is used, and is titrated by precipitating 10 c.c. of the liquid by ammonia in presence of a determined quantity of ferric oxide.

Whichever oxidising agent be employed, lime can be estimated in the usual manner after the separation of the iron and alumina.—C. S.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*Raw and Boiled Milk, Reagents distinguishing between.*R. Dupouy. Bull. Soc. Pharm. Bordeaux, March 1897; Analyst, 1897, **22**, [257], 211.

*Guaiacol*.—Add to 1 c.c. of the sample of milk, an equal volume of a 1 per cent. aqueous solution of guaiacol, and then one drop of ordinary commercial hydrogen peroxide. An immediate yellow colour is produced with raw milk, whilst with boiled milk the mixture remains colourless.

*Hydroquinone*.—1 c.c. of a freshly prepared 10 per cent. aqueous solution, mixed with 3 c.c. of raw milk and 15 drops of hydrogen peroxide, gives an immediate rose coloration, and the mixture, after standing for 3 or 4 minutes, deposits green crystals of quinhydrone,  $C_{12}H_{10}O_4$ .

*Pyrocatechol*.—1 c.c. of raw milk, when mixed with an equal volume of a 10 per cent. aqueous solution of pyrocatechol, gives a yellowish-brown colour after the addition of a drop of hydrogen peroxide.

*$\alpha$ -Naphthol*.—An aqueous solution of the reagent gives a violet-blue colour with raw milk, after the addition of a drop of hydrogen peroxide.  *$\beta$ -Naphthol* does not give this reaction.

*Paraphenylenediamine*.—This reagent gives a very sensitive reaction, and can be used with watered and skimmed milks, which, with the preceding reagents, give the colorations, but with less intensity than normal milk. Several centigrams of the reagent are dissolved in 1 c.c. of water, and to the cooled solution an equal volume of milk and one drop of hydrogen peroxide are added. A very dark violet colour is produced with raw milk.—A. S.

*"Dulcine," or Paraphenetol Carbamide.* R. Raggeri.

Ann. del. Lab. Chim. Centr. delle Gabelle III., 138—145.

PARAPHENETOL has been introduced into commerce as a sweetening material under the various names of suciole and dulcine, especially as it has been shown that even repeated doses are innocuous to the human organism.

The first method adopted for the detection of this substance, was proposed by Berlinerblau and modified by Morpurgo, but Thoms subsequently affirmed that the reaction was not characteristic of paraphenetol-carbamide, as phenetidine salts and phenacetine equally give the same result. The method proposed by the author is as follows:—A fragment of the substance is heated in a porcelain dish with a 6 per cent. solution of silver nitrate, or with a 5 per cent. solution of mercuric chloride, operating with 2 c.c.; the whole is evaporated to dryness on a water-bath, when a brilliant violet coloration is produced, which becomes more marked if the residue is heated to 160°, especially if mercuric chloride be used. In the case of foodstuffs, the process proposed by Morpurgo for the extraction of the dulcine, gives satisfactory results. While the paper was in course of preparation, a somewhat similar method, namely, by using mercuric nitrate, was proposed by Jorissen (this Journal, 1896, 620); the author has investigated this method, and finds that 0.01 grm. of dulcine gives a very marked, but 0.001 grm. a slight but sensible reaction.

—V. H. V.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Acetylene, Method of Estimating.* Chavastelon. Comptes Rend. **125**, [4], 245—246.

The action of acetylene on an excess of silver nitrate resulting in the liberation of nitric acid, according to the equation:  $C_2H_2 + 3AgNO_3 = C_2Ag_2.NO_3Ag + 2HNO_3$  (Comptes Rend. 1897, [21], 1264), the weight or volume of acetylene taking part in the reaction can be determined by titrating the free acid, provided the gases associated with acetylene (in mixtures) are inert towards nitric acid, and are

not themselves acid in character. The only data necessary in the calculation are: the volume, temperature, and pressure of the acetylene or mixed gas, and the final volume and acidity of the liquid.

The operation may be performed in a Ruoult eudiometer, 20 c.c. of a 10 per cent. solution of silver nitrate sufficing for a 60 c.c. eudiometer, distilled water being afterwards run in until the pressure is balanced.

The method is also applicable to acetylides of the formula  $R.C \equiv C.H$ , the reaction in such case being expressed by  $R.C \equiv C.H + 2AgNO_3 = R.C \equiv C.Ag.NO_3 + HNO_3$ .  
—C. S.

*Carbon Bisulphide, Estimation of, in Alcohol, Carbon Tetrachloride, &c. Purification of Commercial Carbon Tetrachloride, and a New Reaction for the same.* W. Schmitz-Dumont. Chem. Zeit. 1897, 21, 487-488 and 510-511.

For the quantitative estimation of carbon bisulphide the following methods have been recommended: (1) Combining with triethylphosphine and weighing the red compound  $P(C_2H_5)_3CS_2$  (Ber. 1880, 13, 1732). (2) Converting into potassium xanthate, and estimating as copper xanthate by titration with copper acetate. (3) Converting into potassium xanthate, precipitating with copper sulphate in an acetic acid solution and igniting as copper oxide. (4) Converting into potassium xanthate, adding lead nitrate to form lead sulphide and weighing as lead sulphate. (5) Converting into lead sulphide and thiocyanate by the addition of a saturated solution of lead acetate (1 vol.), and alcohol saturated with ammonia (10 vols.). (6) Passing in the form of gas over red-hot copper and determining the sulphur in the resulting sulphide (Ber. 2, 741). (7) Passing the gas mixed with hydrocarbons (coal gas) over finely divided and moderately heated platinum and absorbing the hydrogen sulphide in lead solution. (8) Converting into iron sulphide by heating in a sealed tube with a solution of iron chloride and strong ammonia and estimating the sulphur as barium sulphate (this Journal, 1884, 235). (9) Conversion into phenylhydrazine phenylthiocarbazine by the addition of phenylhydrazine (Ber. 24, 788; this Journal, 1891, 578).

For the estimation of carbon bisulphide in alcohol, the method based on the conversion into xanthate appeared to be the most suitable. To increase its accuracy when dealing with small quantities of carbon bisulphide, the sulphur in the xanthate solution was oxidised into sulphuric acid and weighed as barium sulphate. For this purpose finely powdered potassium permanganate was added to a hot alkaline solution of the xanthate until it assumed a permanent red colour. The excess was then removed by acidifying the solution with hydrochloric acid and adding oxalic acid. The presence of manganese did not interfere with the precipitation of the barium sulphate. On applying the method to the estimation of carbon bisulphide in alcohol, it was found that the formation of potassium xanthate was not quantitative, it being impossible to free the alcoholic distillate entirely from carbon bisulphide. Better results were obtained by using metallic salts in conjunction with the xanthic acid reagent. Test analyses made with lead acetate yielded 98.8 per cent. of the carbon bisulphide originally present in the sample operated upon.

The method devised by the author is based upon the following reaction, which gives quantitative results:—

The process is as follows:—10 c.c. of the alcohol are heated with 50 c.c. of an alcoholic solution of silver nitrate (5 per cent.) and 5 c.c. of aniline in a covered beaker for half an hour at 50°–60°. The silver sulphide is collected on a small asbestos filter, washed with alcohol and ether, and fused in a platinum crucible with about 10 times the quantity of a mixture of sodium carbonate (1 part) and potassium nitrate (2 parts). The mass is then dissolved in water, acidified with nitric acid, filtered, and precipitated

with barium nitrate. This process, when applied to carbon tetrachloride, gave equally good results. The author has examined a number of samples of carbon tetrachloride procured by him as being pure productions, in all of which carbon bisulphide was detected, as much as 4 per cent. being found in some cases.

For the purification of carbon tetrachloride prepared from carbon bisulphide, the following method is recommended. About one and a half times the quantity of potash necessary to form the xanthate is dissolved in an equal weight of water. The solution is mixed with 100 c.c. of alcohol, and added to one litre of carbon tetrachloride. The mixture is heated for half an hour to 50–60 with frequent agitation. It is then shaken up with water to remove the xanthate, and the aqueous solution separated from the carbon tetrachloride. This operation is repeated twice with half the quantity of potash. To remove the last traces of alcohol, the product is washed with 500 c.c. of water. It is then dehydrated with solid potash and distilled over paraffin, which retains carbon trichloride, if present. The distillate was found to be quite free from carbon bisulphide. It had a boiling point of 76.3 at 769 mm. (76.5° according to Regnault and Main, and 76.7° according to Thorpe).

On treating carbon tetrachloride with phenylhydrazine to remove carbon bisulphide, and allowing the mixture to remain quiescent at the ordinary temperature, a gradual separation of crystals in the form of long, lustrous needles took place. On warming, the crystals formed more rapidly in the shape of mucous laminae. They proved to be a basic hydrochloride of phenylhydrazine.—D. B.

*Linseed Oil, Investigation of.* H. Amsel. Zeits. für angew. Chem. 1897, 12, 369–370. (See this Journal, 1895, 605 and 814.)

A RECENTLY published paper on linseed oil, by Lippert, confirms the applicability of the author's method, but to prevent misunderstanding, Amsel wishes to make it clear that his saponification number and "water-reaction" only apply to perfectly clear oils and varnishes. Fresh or insufficiently clarified preparations must either be filtered or be allowed to settle until clear. The presence of resin (colophony) is not shown by the addition of water to the alcoholic soap solution (water-reaction); this treatment only produces a cloudiness when mineral and resin oils are present in the sample. Colophony may, however, be detected by the acid value which for pure linseed oil always lies below 3, whilst for colophony the author has found it to vary between 162 and 172.

These methods are not applicable to thickened oils.

The author points out that, although the drying of linseed oil and varnishes is influenced by light and temperature, it forms, if carried out under uniform conditions and in conjunction with other tests, such as the iodine number, a good indication as to the purity of the preparation.

—J. T. C.

*Balsams, Resins and Gum Resins.* K. Dieterich. Chem. Rev. Fett- u. Harz-Ind. 4, [15], 205–208; [16], 215–218.

*A. Cold and Fractional Saponification.*—By the successive action of  $\frac{1}{2}$ -normal alcoholic caustic potash and of aqueous caustic potash of corresponding standard, each during 24 hours in the cold, the complete saponification values of the following substances were obtained:—Peruvian balsam, 260–270; Tacamahaca, 19.6–40.6; Singuis draconis, 95.2–122.2; Euphorbium, 85–91; Laetucarium Anglicum, 75.6; L. Germanicum, 166.6–313.6; Ammoniacum, 148–162; Bdellium, 46.2–81.3; Galbanum, 113.4–141.4; Gamboge, 124.6–128.6. Venice turpentine, asafetida, and olibanum remain unsaponified, and myrrh and tacamahaca are doubtful.

The advantages claimed for this cold method are, that the treatment with alcoholic potash by itself gives the resin number; the resins may be examined in their natural state; the detection of adulterants is facilitated, and no decomposition products are formed.

*B. Acid Number.*—In the resins devoid of esters the presence of the so-called resinolic acids complicates the

titration, by combining a further quantity of alkali on prolonged standing. The author therefore prefers to determine the acid number by back titration, and proceeds by dissolving 1 gram. of substance in 50 c.c. of petroleum spirit (sp. gr. 0.700) and acting on the solution with 50 c.c. of  $\frac{1}{2}$  normal alcoholic potash for 24 hours at room temperature, then titrating back, with or without the addition of 500 c.c. of water. The following results were obtained:—*Colophony*: Estimation of the acid number by back titration has the advantage that the alkali solution serves both to fix the resin acid and also as a solvent, but no addition of water must be made, or otherwise decomposition sets in, and the results give too low a figure. Acid number, 160–170. *Dammar*: without water, 20–30; with, 20–25. Direct titration gives inferior results. *Gumiacum*: the high colour of the solution renders dilution with water necessary. Acid number, 89.6 (direct, 23–24). *Mastic*: the lye suffices as solvent. Acid number (with water): Levantine varieties, 44.8–53.2; Bombay grades, 109.2–113.4. *Olibanum*: no solvent required, but the time of the operation is extended to 48 hours, the acid number then being 12.0–50.4. This is higher if colophony or sandarac has been added, and when these are suspected, no water should be used in the titration, or results will be below the truth. *Dammar* reduces the ester number and saponification value. *Sandarac*: results of direct titration unreliable. No solvent is needed, but water should be used. Acid number, 91–105. *Asafetida*: the conditions resemble those for olibanum. The use of a solvent is objectionable, leading to a loss of volatile constituents. Acid number, direct (alcoholic extract), 11–82; back titration, 68–77. *Ammoniacum* and *Galbanum* require special treatment to obviate loss of volatile matter, 0.5 gram, being placed in a flask with a little water and distilled by direct steam, until 500 c.c. have passed over into the receiver, which contains 40 c.c. of  $\frac{1}{2}$  N aqueous caustic potash. The liquid is then titrated back. Acid numbers: ammoniacum 112–212.8, galbanum 73.50–114.20, those kinds exhibiting the highest number being best suited for pharmaceutical purposes.

In general, the author considers that the drugs themselves should be examined and not merely extracts; furthermore, that back titration and cold saponification afford the most reliable means of attaining the respective objects in view, and that whilst the methods borrowed from fat analysis are generally suitable for all resins, they require to be specially modified in each case. To ensure accuracy, it is desirable to ascertain the acid number and saponification by separate experiments, and the ester number by difference. All results should be referred to the undried drug in its natural condition. The iodine number of the resins is unimportant and sometimes leads to wrong conclusions. Dilution is advisable in all titrations, though care is necessary in adding water, decompositions being sometimes occasioned thereby. In saponification, the fractional cold system is alone capable of giving accurate results. The acid and ester numbers are only valuable in cases where acids or esters are respectively present, *i.e.* ester numbers for copal, dammar, and sandarac are useless. Finally, the conditions prescribed in methods of examination should be strictly adhered to, or concordant results cannot be expected.

The methods proposed are, briefly, as follows:—

*A. Balsams*.—*B. Copaiva*: (a) Acid number.—Dissolve 1 gram. in 200 c.c. absolute alcohol, and titrate with  $\frac{1}{2}$  N alcoholic potash, with phenolphthalein indicator, multiplying result by 5.6. (b) Saponification value.—Dissolve 1 gram. in alcohol, add 20 c.c.  $\frac{1}{2}$  N alcoholic potash, and heat for an hour under inverted condenser. Dilute with 100 c.c. of absolute alcohol, and, when cold, titrate back with  $\frac{1}{2}$  N  $\text{H}_2\text{SO}_4$ . (c) Ester number.—by difference.

*Bal. Peruannum*.—The acid and ester numbers are determined as above, but for the saponification value 1 gram. of substance is exposed to the action of 50 c.c. petroleum spirit (sp. gr. 0.700) and 50 c.c.  $\frac{1}{2}$  N alcoholic potash, for 24 hours at room temperature, in a closed flask, then shaken up with 300 c.c. of water and titrated back with  $\frac{1}{2}$  N  $\text{H}_2\text{SO}_4$ . By warming 1 gram. of the balsam with ether, washing on a filter until the solvent runs away clear and

has ceased to extract, and then drying at 100° C., the percentage insoluble in ether is obtained. To determine the cinnamene present, the ethereal extract is shaken up once with 20 c.c. of 2 per cent. caustic soda, and separated in a funnel, the ethereal solution being then left to evaporate spontaneously and kept all night in the desiccator; the mean of the weighings after 12 and 24 hours gives the weight of cinnamene. The resin ester is thrown down from the alkaline liquid, from the last operation, by dilute  $\text{HCl}$ , filtered, washed under the aspirator until free from chlorine, and dried at 80° till constant. Both the percentage of the ester and its ratio towards the cinnamene should be calculated.

*Bal. Tolutanum*.—Acid number, ester number, and saponification value determined as for *B. copaiva*, except that for the latter test, 96 per cent. alcohol is used for solution and dilution.

*B. Resins*.—*Benzoin*: In addition to the acid, ester, and saponification values, the ash is estimated by incinerating 1 gram., and calcining until the weight is constant. *Colophony*: For the acid number determination, 25 c.c. of  $\frac{1}{2}$  N alcoholic potash are used to 1 gram. of resin, without any other solvent. No water must be added before titrating. The specific gravity is estimated by immersion in six standard solutions of common salt, ranging in density from 1.075 to 1.080, or by the Mohr-Westphal balance.—C. S.

*Molasses, Commercial Analysis of*.—Molhaat. Bull. Assoc. Belge des Chim. 11, [37], 86–88.

Owing to the various changes that have taken place in the methods of manufacture the analytical processes hitherto in use are no longer suitable; the density, for example, giving no indication of the nature of the product; polarisation being unreliable, by reason of the presence of optically active substances other than saccharose, and the Clerget method inapplicable when saccharose, glucose, and raffinose are simultaneously present.

In order to afford the distiller an insight into the probable yield of alcohol obtainable from the molasses, and thus obviate further litigation on the interpretation of the terms "sound, pure, and merchantable," the author proposes to imitate the Denamur method for the commercial analysis of glucose, based on the determination of the fermentable matter in the sample. To this end, 100 grms. of molasses are dissolved in about 200 c.c. of hot water, and boiled along with 1.2–1.5 c.c. of ordinary sulphuric acid, to drive off volatile matters ( $\text{HNO}_3$ ,  $\text{SO}_2$ , &c.). After filtering and washing with hot water, the filtrate is made up to 1 litre, the density (Balling) estimated, and 500 c.c. of the liquid pitched with 25 to 30 grms. of yeast, for fermentation at 28° to 30° C. during 24 hours. The alcohol and carbon dioxide being then driven off by heat, the volume of residual liquid is made up again to 500 c.c., and the difference of density (Ball.) between this and the original solution gives the amount of fermentable matter. To check the result the alcohol may be estimated by distillation.

—C. S.

*Sweet Wines, Determination of Glycerin in*. G. Fabris. Ann. del. Lab. Chim. Centr. delle Gabelle III., 225, 23.

The determination of glycerin in wines, presents considerable practical difficulties, especially in those kinds which contain 15–20 grms. of sugar per 100 c.c., such as Malaga, Samos, and others. Various methods have been proposed, but that of most frequent use and ready application is based upon the elimination of the sugar by means of lime, though this method is not free from defect, since the separated glycerin contains small quantities of sugar, colouring matters, as also of nitrogenous and mineral substances. Though it would appear that the proportion of glycerin found would exceed that present, yet as a matter of fact the error due to the above impurities is greatly exceeded by the errors due to other causes, especially in wine rich in sugar. Such errors arise from the bulky nature of the lime precipitate, the subsequent dilution with alcohol, the loss of glycerin in the evaporation of the alcoholic extracts, &c.

With a view of investigating the question, the author made imitation mixtures containing known proportions of glycerin, invert sugar, alcohol, and caramel; for such mix-

tures the German official method gave satisfactory results, but certain observations on the application of the method, as suggested by practice, in the analysis of wines containing 10—20 per cent. of sugar, and highly coloured, such as red Malaga, are considered by the author to be not wholly unnecessary. Thus the results of experience showed that 10 grms. of lime, and not milk of lime, should be added to each 100 c.c. of wine, and 200 c.c. instead of 100 c.c. of alcohol should be added, and the precipitate obtained should be washed with at least 200 c.c. of alcohol to extract the glycerin as completely as possible. But the great disadvantage of the German method is the time required. The author has examined that proposed by Lecco (Ber. 1892, 2094), and a somewhat similar method has been used in the Italian laboratory for some time past; in both cases satisfactory results are obtained if certain precautions are adopted, especially the cessation of the evaporation of the mixture of wine and lime when it has become of the consistency of sludge: if the evaporation is carried beyond this point there is a considerable loss of glycerin.—V. II. V.

*Soap, Analysis of.* R. Moreschini. Ann. del Lab. Chim. Centr. delle Gabelle III, 107—118.

In the course of commercial practice in the analysis of soaps, the following problems are presented. Firstly to determine the materials, and secondly the proportions in which they were originally mixed; the latter problem is, however, almost impossible, owing to the similarity of the composition of such materials. The author succeeded in obtaining from an Italian manufacturer the specifications of five kinds of soap used commercially under the names of (1) mottled, (2) extra green, (3) green, first quality, (4) yellow, first quality, and (5) yellow, third quality. In the samples not containing resin, determinations were made of the proportion of fatty acids, their acid and iodine values, as also of the Reichert value; for those containing resin, the method proposed by Gladding for its estimation was found to give satisfactory results. The values calculated from the known acidity and iodine numbers of the oils used in manufacture are compared with those found on analysis, and the conclusion is drawn that the methods applied give results sufficiently approximate for the purpose.—V. H. V.

*Caffeine, Determination of in Coffee.* E. Tassilly. Bull. Soc. Chim. 17, [15], 76].

REVIEWING the various methods which have been suggested for the determination of caffeine in coffee, the author classes them according to the solvent employed for extraction. The first group includes those in which chloroform is the solvent; the second, those extracted by means of hot water; and the third, those in which the solution of an organic salt furnishes the menstruum.

In the first group the process of *Commaille* is the oldest: as modified by *Cazenave* this consists in extracting a mixture of coffee and slaked lime, by digestion with chloroform. *Petit* has shown that in order to obtain the whole of the alkaloid in the case of tea, the mixture of the two powders must first be moistened to ensure the subsequent removal of all the caffeine. *Grandval* and *Lajour* treat the coffee first with ammoniacal ether, and then extract with chloroform by digestion.

In the second group, the process of *Domergue* and *Nicolas* consists in precipitating an aqueous infusion of coffee with mercuric acetate. The filtrate, mixed with sand and magnesia, is evaporated to dryness. The dry residue is then exhausted with chloroform. *Deorkovitch* makes three infusions, followed by two decoctions, giving a litre of aqueous extract in all from each 10 grms. of coffee taken. This is precipitated with baryta and filtered, the filtrate is washed with petroleum ether; then extracted with chloroform. *Guillot* merely exhausts the substance with successive boilings and washes out the alkaloid with chloroform.

In the third group, *Herlaut's* method consists in the use of a solution of sodium benzoate as a solvent, the coffee having first been mixed with lime. The caffeine is removed from the extract by shaking out with chloroform. *Gorges* prefers simple lixiviation with salicylate of sodium.

After adversely criticising each of these processes *seriatim*, the author proposes the method given below. —J. O. B.

*Caffeine in Coffee, New Method of Estimating.* E. Tassily.  
Bull. Soc. Chim., 1897, **17**, [15], 706.

Five grams. of powdered coffee are treated with three successive volumes, each of 200 c.c. of boiling water, infusion being prolonged for 10 minutes in each case. After decantation, another 200 c.c. of water are added to the residue and the mixture is heated until the liquid begins to be coloured; this is then decanted and the process repeated with another similar quantity of water, so that the volume of the total aqueous extract is 1 litre. This liquid is divided into equal volumes, each of 500 c.c. These are evaporated to dryness on the water-bath, then treated with 1 or 2 c.c. of 10 per cent. sulphuric acid, thoroughly stirred, and then extracted with small quantities of boiling water on filters, until the filtrates cease to give a precipitate with a solution of tannin, or a red coloration with Gaucher's test.

From these slightly acid solutions the caffeine may be extracted in two ways. In operating, as indicated, on 10 grms. of coffee, it is as well to treat one 500 c.c. by the first process given below, and the other by the second. Of the two, the latter is to be preferred as the alkaloid is obtained from it in a perfectly pure condition.

(1.) The solution is evaporated to dryness on the water-bath, adding, at the last, 20 grms. of washed sand, and 2 grms. of calcined magnesia. The dry mixture is transferred to an extractor and treated with 100 grms. of chloroform until exhausted, which will be in three or four hours. The solvent is then distilled off, and the residue weighed after drying at 100° C.

(2.) The other 500 c.c. is made faintly alkaline with ammonia, and extracted with several successive portions of chloroform until nothing more is removed by that solvent. The chloroform is then distilled to a small bulk, the residue decanted into a tared dish, evaporated and weighed. The latter method invariably gives slightly higher figures than that in which the solvent is employed hot.

The following are comparative results obtained by the author with various processes, on the same samples of coffee, previously dried at 110° C.:—

	New Caledonia.	Liberia.	Mocha.
New process (cold chloroform)	1'44	1'40	1'48
" " (hot) "	1'36	1'34	1'48
Dörmegis and Nicholas' process	1'34	1'34	1'45
Gargès' "	1'40	1'36	1'45
Herlaut's "	1'40	1'35	1'43
Delecour's "	1'40	1'37	1'42
Dworkovitch's "	1'40	1'35	1'45

The author has assured himself that every trace of caffeine is removed by his method, and also that no loss of alkaloid occurs: a known amount of caffeine added to one of the two portions of the liquid, after infusion being found again within the limit of experimental error.

—J. O. B.

## XXIV.—SCIENTIFIC &amp; TECHNICAL NOTES.

*Iron Chloride, Hydrolysis of.* W. Spring. Chem. Zeit.  
1897, **21**, [66], 651.

It is stated that ferric chloride in aqueous solution does not change directly into colloidal ferric hydrate and hydrochloric acid, but that an intermediate decomposition first takes place, similar to that of the vapour at a high temperature and resulting in ferrous chloride and chlorine. The chlorine set free, reacts with the water with formation of electrically neutral hydrochloric acid and active oxygen, and the latter combines with the ferrous chloride, forming, so long as the temperature undergoes, no change, equal proportions of ferric hydrate, hydrochloric acid, ferric chloride and water.

—A. S.

*Acetylene, The Formation of Mixed Hydrates of.* De Forerand and S. Thomas. *Comptes Rend.* 1897, **125**, 109—111.

By the interaction of acetylene, water and carbon tetrachloride at 0° and under a pressure of about 20 atmospheres, a crystalline product is obtained, which is stable at 5° and at a pressure scarcely above that of the atmosphere; at a higher temperature it decomposes with evolution of acetylene. It is assumed to be a mixed hydrate of acetylene and carbon tetrachloride. Similar mixed hydrates have also been obtained by employing other halogen derivatives in the place of the carbon tetrachloride, and crystals have also been obtained with other gases, namely,  $C_2H_2$ ,  $CO_2$ ,  $SO_2$ , in the place of acetylene.—A. K. M.

*Ethylene, Synthesis of: Action of Nickel upon Ethylene.* P. Sabatier and J. B. Senderens. *Comptes Rend.* **124**, 1358.

When a slow current of pure ethylene is passed over the surface of nickel reduced by hydrogen, and heated to above 320° C., the gases obtained after removing traces of undecomposed ethylene by means of bromine are found to consist of a mixture of ethane, formene, and hydrogen, with possibly an infinitesimal trace of higher hydrocarbons.

—J. O. B.

*"Active" Oxygen (the so-called) and Peroxide Formation.* C. Engler and W. Wild. *Ber.* 1897, **30**, [12], 1669—1681.

In the oxidations produced by free oxygen, it has been frequently observed that a second substance present, which is entirely unattacked by ordinary oxygen, is energetically oxidised. Many explanations of these phenomena have been given: change of oxygen into ozone and antozone (Schonbein), existence of oppositely charged atoms in the oxygen molecule (Brodie and Clausius), formation of free oxygen atoms, &c. M. Tschube supposed that in the oxidation of zinc there occurs the process represented by the following equation:—

and showed that the amount of hydrogen peroxide produced agreed with this hypothesis, which, however, only explains such oxidations as proceed in the presence of water.

Vau't Hoff and Jorissen have shown that the spontaneously oxidisable substance renders capable of oxidation exactly as much oxygen as it itself absorbs; they assume that the oxygen molecule splits up into atoms of different electrical charges, one of which is by preference absorbed by each substance present; and Ewan, on this hypothesis, has found that ordinary oxygen must be already slightly dissociated in this way.

The authors put forward the hypothesis that "in spontaneous oxidations not single oxygen atoms but whole molecules are taken up, the double union of the atoms in the molecule being disturbed, with formation of peroxides of the type—

These compounds give up (like hydrogen peroxide) one oxygen atom to another oxidisable substance, thus passing into ordinary oxides.—A. C. W.

*Aldehydes, Synthesis of Aromatic.* L. Gattermann and J. A. Koch. *Ber.* **30**, 1622—1624.

The method consists in acting on toluene and its homologues with hydrochloric acid and carbonic oxide in presence of aluminium chloride and cuprous chloride. A current of carbonic oxide and hydrochloric acid is passed through a mixture of 30 grms. of toluene, 45 grms. of finely powdered freshly prepared aluminium chloride, and 5 grms. of cuprous chloride, at a temperature of 20—25° C. with good agitation. The carbonic oxide passes through at

the rate of 3 litres per hour, whilst the hydrochloric acid is passed through at half that rate. The dark viscid product of the reaction is poured on to ice, the oil separated, and the aldehyde and unaltered toluene blown over with steam. The distillate is treated with sodium bisulphite, separated from unaltered toluene (about 8 grms.), the aqueous solution decomposed with anhydrous soda, and the aldehyde again blown over with steam. After taking up with ether and evaporating off, about 20—22 grms. of perfectly pure *p*-tolyl aldehyde remains; this, on oxidation, gives *p*-toluic acid. The method gives satisfactory results also with *o*-, *m*-, and *p*-xylene, ethylbenzene, mesitylene, and other substances.—T. A. L.

*Caffetannic Acid, The so-called (Glycosylcaffèic Acid), and its Successive Decomposition to Caffèic Acid, Vinylpyrocatechol and Pyrocatechol.* H. Kruiz-Krause. *Ber.* 1897, **30**, [12], 1617—1622.

The tannic acids of coffee and maté, on decomposition, yield sugars and dihydroxycinnamic acid (caffèic acid). Hoffmann states that this acid melts at about 213°, with browning and incipient decomposition; at 200°, however, it is quantitatively decomposed into carbon dioxide and vinylpyrocatechol,  $C_6H_3(OH)_2 \cdot C_2H_3[CH_2O : OH : 1 : 3 : 4]$ . The latter cannot be distilled *in vacuo* without a decomposition which produces pyrocatechol. The often observed formation of protocatechuic and acetic acids in the fusion of so-called tannic acids with potash, is explained by the following reaction of caffèic acid:—

—A. C. W.

*Caffetannic Acid.* Cazeneuve and Haddon. *Comptes Rend.* 1897, **124**, [25], 1458—1460.

CAFFETANNIC acid has usually ascribed to it the formula  $C_{15}H_{13}O_8$ , and is regarded as a glucoside formed by the addition of caffèic acid and mannitol, with elimination of  $H_2O$ . Preparing a solution of caffetannic acid according to the directions of Hlasiwetz, and treating this with phenylhydrazine and acetic acid, the author obtained yellow well-crystallised needles of an osazone, the analysis of which yielded results (C, 62·8; H, 5·9; N, 13·04 to 13·28) closely agreeing with those (C, 62·7; H, 5·5; N, 13·02) corresponding to the formula—

the osazone of a substance—

which should therefore be the formula of caffetannic acid. According to this, caffetannic acid must be regarded as formed from a molecule of caffèic acid and two molecules of a sugar,  $C_6H_{12}O_6$ , with elimination of  $2H_2O$ . The authors have this sugar under investigation.—J. T. D.

*Oxidation and Chlorination. A Method of [by the Aid of Salts of Manganese].* A. Villiers. *Comptes Rend.* **124**, 1349.

When an oxidisable body is placed in a medium capable of supplying oxygen, but under such conditions that oxidation does not take place, or proceeds but slowly, the addition of a trace of a salt of manganese brings about, or very materially accelerates the reaction. Thus if a mixture be made of equal volumes of saturated solution of oxalic acid, of hydrochloric acid, 25 per cent., and of nitric acid of the same strength, no gas is evolved even after prolonged contact. If, however, after raising the temperature of the mixture to boiling point, a trace of any salt of manganese be added, such as a few drops of solution of the sulphate, reaction takes place almost immediately, and the evolution of carbonic acid gas continues regularly, particularly if a few fragments of gas carbon be introduced into the liquid. If heating be continued, the whole of the oxalic acid is rapidly used up, and the process can be continued indefinitely by introducing more of that substance, and more nitric acid, to furnish the requisite oxygen. The

manganese salts appear to act as carriers of oxygen, probably by the formation of intermediate unstable oxy-salts; their behaviour may almost be compared with that of the oxidising ferments. It is possible that manganese, which is so widely distributed in the animal or vegetable organism, thus plays an important and hitherto unsuspected part in physiology, since its presence may be necessary for the oxidation of carbohydrates and nitrogenous bodies. In therapeutics too, the salts of manganese should prove useful in the treatment of those diseases, such as diabetes and arthritis, which arise from defective physiological oxidation.

Sucrose, glucose, and members of the fatty series are oxidised under like conditions in the same manner as oxalic acid; with substances of the aromatic series, however, even when they contain fatty bodies, oxidation does not result, but chloro-substitution bodies are formed. Thus when benzene or toluene are heated with aqueous solutions of nitric and hydrochloric acid, with a trace of a manganese salt added, reaction takes place slowly even in the cold; the lower surface of the liquid, which is in contact with the aqueous solution, is, in the course of a few days, so far altered that chloro-substitution products are formed, which being of a greater density, fall to the bottom. This method of chlorination promises to be useful for technical purposes. —J. O. B.

*Oxidations [Drying Oils], The Part played by Manganese in.* A. Lévache. *Comptes Rend.* 1897, **124**, [25], 1520—1521.

REFERRING to the paper of Villiers (see preceding abstract), the author points out that in 1883 he remarked on the effect of manganese in hastening the oxidation of drying oils, the same oil being completely oxidised in six hours when it contained a little manganese, while with lead it needed 24, and with iron 48. In all such actions the manganese probably acts simply as a carrier of oxygen; no doubt the action of all oxydases (see next abstract) is a similar one.—J. T. D.

*Oxidising Action of Salts of Manganese, and the Chemical Constitution of the Oxydases.* G. Berraud. *Comptes Rend.* **124**, 1355.

It is found that the salts of manganese, *per se*, act as carriers of oxygen. When introduced in aqueous solution together with a body capable of oxidation, such as hydroquinone, into a flask fitted with a stop-cock, and kept continually agitated for a prolonged period, by means of a water wheel, considerable diminution of the amount of oxygen in the atmosphere of the vessel is observed. This varies with the salt of manganese employed, as will be seen from the following results. The same quantity of hydroquinone and water were used in each case:—With nitrate, 1.5; sulphate, 1.6; chloride, 1.8; benzoate, 7.4; acetate, 15.3; salicylate, 15.7; lactate, 16.3; glucinate, 17.6; and succinate, 22.1 c.c.

It would appear that the salt of manganese in aqueous solution undergoes partial hydrolysis, with the formation of free acid and manganous oxide, thus:—

The manganous oxide thus formed, as is well known, is oxidised in the air, and the molecule of atmospheric oxygen thus split up leaves one atom free to combine with any oxidisable body:  $MnO + O_2 = MnO_2 + O$ .

It is found that a solution of hydroquinone containing manganous oxide in suspension gives at once, on exposure to the air, quinone and manganese dioxide. The dioxide so formed is again reduced in an acid solution, forming a manganous salt and a further quantity of quinone. Thus, a small amount of a salt of manganese may serve as a carrier of oxygen to an unlimited quantity of hydroquinone. The theory of hydrolysis of the salt is supported by the fact that the salts of the organic acids, having a high molecular weight, and a relatively low affinity for the metal, and which are therefore most easily hydrolysed, are those which act most energetically as oxidisers. It would seem, therefore, that in the case of oxydases—which are regarded as manganese compounds in which the albu-

minoids play the part of very feeble acids, having only just sufficient affinity for the metal to keep it in solution—the oxidising power is due to the manganese, the albuminoids giving to these ferments only their peculiar physical and chemical properties.—J. O. B.

*An Organic Substance rich in Manganese extracted from Woody Fibre.* G. Guérin. *Comptes Rend.* 1897, 311—312.

Sawdust is digested for 2—3 days with distilled water containing 1 per cent. of pure caustic potash. The brown solution obtained after filtering, when treated with a slight excess of hydrochloric acid, gives a voluminous precipitate, which can be easily washed by decantation with water containing a trace of hydrochloric acid to prevent dissociation. The product is then dissolved with a few drops of ammonia, reprecipitated with hydrochloric acid, washed as above, and dried. It forms a brown powder, and the particular sample examined from beech sawdust, did not contain any iron, but a considerable proportion of manganese, phosphorus, and sulphur, and gave the following percentage numbers on analysis:—C = 52.762, H = 5.04, N = 4.60, S = 0.666, P = 1.297, Mn = 0.402. The author considers it probable that manganese, combined in a nucleus, exists in all woody fibres.—T. A. L.

## PATENT.

*Plants, Leaves, and the like; Impts. in or relating to the Treatment and Preservation of.* A. J. Boulton, London. From R. L. and K. R. Kesterstein, Dresden. Eng. Pat. 14,825, June 18, 1897.

IN the treatment of the dry parts of plants, leaves, &c., so as to give them a life-like appearance, the ordinary process may be much shortened by a preliminary treatment with more or less diluted sulphuric acid, which thoroughly softens or dissolves the outer coating; the subsequent treatment with glycerin and dyestuff can then be effected simultaneously in the same bath, and the dyestuff being more perfectly absorbed a better result is obtained. The process then consists of (a) treatment with acid, (b) washing, (c) partly drying, (d) immersion in a bath of glycerin and dyestuff containing a salt of nitric acid, acetic acid, and gelatin, (e) drying sufficiently for (f) varnishing. If paint is to be applied as well as or instead of the dyestuff, it may be mixed with the varnish or applied just before.—L. A.

## EDUCATIONAL.

CONTINENTAL TECHNICAL SCHOOLS.—REPORT OF THE MANCHESTER DEPUTATION.

*Chem. Trade J.*, Oct. 2, 1897, 210.

IN pursuance of a resolution of the Technical Instruction Committee, confirmed by the Manchester City Council, a deputation, comprising Mr. Alderman Hoy, Mr. Alderman Crossfield, Mr. N. Bradley, Mr. Ivan Levinstein, Mr. John Craven, Mr. Charles Rowley, and Mr. J. H. Reynolds recently visited a number of institutions and schools on the Continent, devoted mainly to scientific and artistic instruction as applied to industrial and commercial pursuits. In their report to the Committee the deputation mention the fact that in 1891 a visit was paid to several of the more important technical schools in France, Germany, Austria, and Switzerland, and that a report was then issued showing the extent to which provision had been made for the supply of instruction of a scientific and technical character in aid of the commerce and of the industries of those countries. "In the meantime," the report proceeds, "the council has undertaken the responsibility of maintaining the technical and art schools of the city, and, with the purpose of giving full effect to that responsibility, has already not only greatly developed these institutions, but has embarked upon the erection of the largest technical school in the country, the proper equipment of which is a matter of the most serious concern and importance. The erection of the new school was begun in August 1895, and its completion, ready for the occupation, is confidently expected at an early date. The Committee therefore feel that it is high time the question of the equipment of the school was considered, especially in respect

of the important departments concerned with the textile industries, with the industrial application of chemistry, and of physics in relation to electrical engineering. . . . Your Committee felt that it would be the height of unwisdom, having in view the serious responsibility of equipping the new Municipal Technical School in Manchester so as to meet adequately and effectively the demands of a great industrial centre such as this, were they to neglect the opportunity of seeing what Continental countries have done of late, and what they are now doing in this regard. Especially is this a necessity with respect to the extraordinary development which has taken place within quite recent years in electrical science as applied to electrical engineering industries, and with the certainty of great extension in the near future. Hardly less important is the great textile industry in its various departments of spinning, weaving, designing, dyeing, and finishing, in some of which we find ourselves at a serious disadvantage (especially those in which chemistry plays a part) as compared with our foreign competitors. It has been found necessary in the dyeing and finishing schools abroad to discard mere laboratory methods, and to equip them on a scale approaching that of the works themselves, and analogous to the practice obtaining in the spinning and weaving schools, so as to give the students who are trained in them a real, practical, and effective knowledge of the processes employed." Reference is then made to what the deputation saw at Crefeld and in its well-equipped textile and dyeing schools. "Your deputation is convinced," says the report, "as a result of the inspection of the Crefeld School, that this district would gain materially by the development of our textile school in the new building on the same lines. 1. By the increase in the number and variety of the looms and of the goods woven upon them. 2. By the establishment of a school of tinctorial chemistry, and of practical dyeing and finishing upon an adequate scale, alike in respect of the completeness and the real efficiency of the machinery employed. 3. By the establishment, in actual touch with the other departments of the school, of a well-organised museum, replete with examples of ancient, mediæval, and modern productions of the best type of workmanship, colour, and design. It is to variety and excellence in these respects that Lancashire must look to maintain and increase its supremacy and reputation as a manufacturing centre." From Crefeld the deputation went to Aix-la-Chapelle, thence to Berlin, Darmstadt, Dresden, Vienna, and other places. After dwelling on the zeal shown by Germany in technical training, the deputation remark: "That Germany is in a prosperous condition, due to her successful manufacturing and commercial enterprise, was plainly evident on every hand in the extension of her cities—the making of new streets and the erection of fine, handsome buildings which is going on everywhere in her large towns. It is not less clear that the schools are the root and base of this surprising industrial development, and are the main contributors to this great economic result; it is no less certain that if we are to maintain our position as a great industrial community it must be by following and adopting the same methods. It is not, however, only in the domain of science that Germany is making great progress. In almost every town visited by the deputation fine industrial art museums were found, arranged with the express purpose of cultivating a knowledge of what has already been accomplished in the production of fine examples of colour, design, and workmanship. Every technical school has its special museum of objects applicable to its purposes. Notably was this the case in Berlin, Vienna, Nuremberg, Crefeld, and at Düsseldorf, in which latter place the Industrial Art Museum is said to be the finest in the Rhineland. These museums help to preserve and hand down the traditions of past achievement and excellence, and stimulate the desire to reach to as high or higher levels to-day." In concluding their report the deputation express their sense of the advantage, whatever the ultimate drawbacks, of a centralised bureaucratic administration, which, taking a careful survey of the educational and industrial needs, placed the schools here or there, as circumstances required, brought them into mutual relation, supplied ample means, and effectively assisted, without loss of time, the industrial advance. "Something might be lost of 'freedom, variety, and elasticity,'

and that loss might ultimately be serious in its effect upon individual initiative, upon which we as a nation so confidently relied. Which was the better policy the future could alone determine. It might, however, be safely asserted that it was high time the effort was made in this country to give to our youth the educational advantages, general and special, which were enjoyed by their rivals abroad. Exception had sometimes been taken to the size and cost of the new buildings now being erected by the Technical Instruction Committee for the Municipal Technical School, but the deputation, had returned from their visit doubly confirmed in their conviction that every foot of space would be needed, and that even when fully utilised and equipped it would fail to rival in amplitude of resource the splendid industrial schools of Germany and Switzerland.

#### COMMERCIAL READING ROOM AT THE IMPERIAL INSTITUTE.

A commercial reading room has been established at the Imperial Institute, and is open for the free use of the general public. It is supplied with the principal British commercial and technical publications, and a number of similar prominent Indian, colonial, and foreign periodicals. Visitors to the reading room can also consult a large collection of directories, almanacs, official year-books and hand-books, Government gazettes, diplomatic and foreign consular reports, market reports, prices current and statistics, trade circulars and catalogues, and an extensive collection of colonial and Indian maps. Inquiries relating to commercial and industrial matters, to emigration, &c., addressed personally, or by letter, to the Commercial Intelligence Department of the Institute, are promptly dealt with.

### New Books.

THE PRINCIPLES OF CHEMISTRY. By D. MENDELÉEFF. Translated from the Russian (Sixth Edition) by GEORGE KAMESKY, A.R.S.M., of the Royal Imperial Mint, St. Petersburg, &c. Edited by T. A. LAWSON, B.Sc., Ph.D. In two volumes. Longmans, Green, and Co., 39, Paternoster Row, London; also New York and Bombay. 1897. Price 36s.

Two 8vo volumes, containing preface to the English Translation and author's preface to the Sixth Russian Edition, tables of contents to Vols. I. and II., and in Vol. I. 621 pages of subject-matter and 78 illustrations; whilst in Vol. II., following the table of contents, there are 499 pages of subject-matter and 19 illustrations. Just preceding the table of contents in Vol. I. are two tables: Table I. The Distribution of the Elements in Groups and Series; and Table II. The Periodic System and Atomic Weights of the Elements. Forming a kind of frontispiece to Vol. II., is a Table showing the periodic dependence of the composition of the simplest compounds, and properties of the simple bodies upon the Atomic Weights of the Elements. At the end of Vol. II. are alphabetical indexes of authors and of subject-matter for the entire work. The contents of Vol. I. are given and subdivided as follows:—I. Water and its Compounds. II. Composition of Water. Hydrogen. III. Oxygen and the chief aspects of its Saline Combinations. IV. Ozone and Hydrogen Peroxide. Dalton's law. V. Nitrogen and Air. VI. The Compounds of Nitrogen with Hydrogen and Oxygen. VII. Molecules and Atoms. The Laws of Gay-Lussac and Avogadro-Gerhardt. VIII. Carbon and the Hydrocarbons. IX. Compounds of Carbon with Oxygen and Nitrogen. X. Sodium Chloride. Berthollet's Laws. Hydrochloric Acid. XI. The Halogens; Chlorine, Bromine, Iodine, and Fluorine. XII. Sodium. XIII. Potassium, Rubidium, Cesium, and Lithium. Spectrum Analysis. XIV. The Valency and Specific Heat of the Metals. Magnesium, Calcium, Strontium, Barium, and Beryllium. The Contents of Vol. II. are sketched as follows:—XV. The Grouping of the Elements and the Periodic Law. XVI. Zinc, Cadmium, and Mercury. XVII. Boron, Aluminium, and the Analogous Metals of the Third Group. XVIII. Silicon and the other Elements of the Fourth Group. XIX. Phosphorus

and the other Elements of the Fifth Group. XX. Sulphur, Selenium, and Tellurium. XXI. Chromium, Molybdenum, Tungsten, Uranium, and Manganese. XXII. Iron, Cobalt, and Nickel. XXIII. The Platinum Metals. XXIV. Copper, Silver, and Gold. Appendix:—I. An attempt to apply to Chemistry one of the Principles of Newton's Natural Philosophy. II. The Periodic Law of the Chemical Elements (The Faraday Lecture). III. Argon: A New Constituent of the Atmosphere.

**JAHRBUCH DER CHEMIE.** Bericht über die wichtigsten Fortschritte der reinen und angewandten Chemie. Unter Mitwirkung von H. BECKurts, C. A. BISCHOFF, E. F. DÜRRE, J. M. EDER, P. FRIEDLÄNDER, C. HAUSSERMANN, F. W. KÜSTER, J. LEWKOWITSCHE, M. MARCKER, F. RÖHMANN, K. SEIBERT. Herausgegeben von RICHARD MEYER (Braunschweig). VI. Jahrgang. 1896. Friedrich Vieweg und Sohn, Brunswick. 1897. Price M. 15. H. Grevel and Co., 33, King Street, Covent Garden, London, W.C.

8vo volume containing 525 pages of subject-matter, and alphabetical indexes of subject-matter and authors. The work commences with a short preface by the editor, Richard Meyer, and with regard to the subjects treated of, these are given as follows, and are contributed by the authors following the subjects numbered. I. Physical Chemistry (Küster). II. Inorganic Chemistry (Seibert). III. Organic Chemistry (Bischoff). IV. Physiological Chemistry (Röhmman). V. Pharmaceutical Chemistry (Beckurts). VI. Chemistry of Foodstuffs, &c. (Beckurts). VII. Agricultural Chemistry (Mäcker and Naumann). VIII. Metallurgy (Dürre). IX. Fuels and Explosives (C. Haussermann). X. Technology of the Carbohydrates and of Fermentation (Mäcker and Naumann). XI. Technology of the Fats and Petroleum (Lewkowitzsch). XII. Chemistry of Tar Products and Colours (Richard Meyer). XIII. Chemical Technology of Textile Fibres (Friedländer). Photography (Eder and Valenta).

**CHEMISCH-TECHNISCHES REPERTORIUM.** Uebersichtlicher Bericht über die neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der technischen und industriellen Chemie, mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 36. Jahrgang. 1897. Erstes Halbjahr. Zweite Hälfte. Mit in den Text gedruckten Illustrationen. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder, S.W., Schönebergerstrasse 26. London: H. Grevel and Co., 33, King Street, Covent Garden.

This number, for the second half-year of 1897, treats of the following subjects of Applied Chemistry:—Foodstuffs. Paper. Photography. Residual Matters. Manures. Disinfection and Sanitation. Soaps. Matches and Explosives. Preparation and Purification of Chemicals. Chemical Analysis. Apparatus. Machinery. Electro-technology. Thermo-technology. Adulteration of Trade Products, &c. New Books.

**ORGANIC CHEMISTRY FOR THE LABORATORY.** By W. A. NOYES, Ph.D., Professor of Chemistry in Rose Polytechnic Institute, Terre Haute. Ind. Chemical Publishing Co., Easton, Pa. 1897. Price 1.50 dols.

This small work is very similar to that of Fischer, Cohen, Gattermann, and others, to whom, indeed, the author acknowledges his indebtedness.

The subject-matter fills 240 pages, and there is an alphabetical index. The work may be defined as one of Organic Chemical Preparations, Reactions, and Separations. It is subdivided as follows:—Chapter I. Acids. II. Derivatives of Acids. III. Halogen Compounds. IV. Nitro Compounds. V. Amines. VI. Hydrazo. Azo. Diazo Compounds, &c. VII. Alcohols and Phenols. VIII. Aldehydes, Ketones, and their Derivatives. IX. Sulphonic Acids and Sulphine Compounds. X. Hydrocarbons. XI. Miscellaneous Compounds. XII. Qualitative Examination of Organic Compounds.

## Trade Report.

### OFFICIAL NOTICES.

#### ACETYLENE GAS.

The Explosives Department of the Home Office has recently had under consideration the question of the restrictions to be applied to the manufacture and keeping of acetylene gas, and has conducted various experiments with the object of gaining information on this matter. The results show conclusively that acetylene gas *per se*, when under a pressure of something less than two atmospheres, is violently explosive; whereas, at a pressure of less than one and a half atmospheres, it appears to be reasonably free from liability to explosion, provided it is not admixed with oxygen or atmospheric air.

For commercial and practical purposes, it is considered sufficient to allow a pressure of 20 ins. of water above that of the atmosphere (*i.e.*, roughly about  $1\frac{1}{2}$  atmospheres), and it is accordingly proposed to draw the safety line at this point, and to declare acetylene when subject to a higher pressure to be an "explosive" within the meaning of the Explosives Act, 1875.

In France and Germany, the authorities have fixed the limit of danger at  $1\frac{1}{2}$  and  $1\frac{1}{10}$  atmospheres respectively, and have imposed prohibitions or restrictions on the keeping or manufacture of the gas when it is at a higher pressure.

Whitehall.

5th October 1897.

#### EXPLOSIVES IN COAL MINES ORDER, 1897.

##### Memorandum.

1. Arrangements have now been completed for testing explosives (at the Home Office Testing Station, Royal Arsenal, Woolwich), with a view to their being admitted to the list of permitted explosives, which it is proposed to substitute for the list contained in the schedule to the above order. The explosives on the permitted list at present in force will have to be submitted to the test, and pay the fee accordingly.

2. Any person wishing to have an explosive tested must fill in the accompanying application form, and forward it, together with a fee of 25*s.*, to the Under Secretary of State, Home Office, Whitehall, S.W.

3. Instructions will then be given as to the samples to be sent for testing.

4. The samples will be tested in the order, so far as practicable, in which they are received; and notice of the day and hour of the test will be sent to the applicant, who will, on prior application, receive a permit authorising him (by or with a representative named by him) to be present at the test. The test is described in an appendix.

5. All explosives which pass the test will be put on the permitted list, but in the event of an explosive failing to pass the test, it will be open to the applicant to apply for a further trial, for which a further fee must be paid of 15*s.*

6. In this further trial the Secretary of State reserves a right to make any variation in the conditions of the test which may appear to him to be necessary to meet any special circumstances.

7. The permitted list is liable to revision from time to time, and explosives on the permitted list will be liable to occasional re-testing.

8. Applications from manufacturers, importers, mine owners, miners, and others interested, will be entertained for the re-testing of explosives on payment of a fee of 2*s.* for a minimum of 10 shots. Additional shots to be paid for *pro rata*.

9. If at any time an explosive is found in practical use to have caused explosions, or on examination or re-testing to be of bad manufacture, or otherwise likely to be dangerous, the Secretary of State reserves to himself the right, after such special inquiry as he may direct, of removing the explosive from the permitted list or of prohibiting its use when made by a particular manufacturer.

10. Facilities will be given for samples to be tested for experimental purposes in connection with the working out of new explosives for use in coal mines, on payment of fees to be determined in each case; but no explosive will be received for firing, even experimentally, which has not previously been placed on the list of authorised explosives issued by the Home Office.

V. D. MAENDIE, Colonel.

H.M. Chief Inspector of Explosives.

Home Office,

Whitehall, S.W.

8th October 1897.

## TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

NEW CUSTOMS TARIFF OF CANADA.

(Continued from page 796.)

No.	Article.	Rate of Duty.
339	Wool pulp .....	25 % <i>ad val.</i>
341	Vulcanised fibre and like material .....	25 % <i>ad val.</i>
372	Gold, silver, and aluminium leaf, Dutch metal leaf, bronze powder, and gold liquid paint.	25 % <i>ad val.</i>
<i>Minerals.</i>		
337	Asbestos in any form other than crude, and all manufactures thereof.	25 % <i>ad val.</i>
351	Plumbago, not ground or otherwise manufactured.	10 % <i>ad val.</i>
375	Plumbago, ground, and manufactures of, n.e.s., and foundry frames of all kinds.	25 % <i>ad val.</i>
413	Gunpowder.	Per lb. 0 8
414	Nitro-glycerin, giant powder, nitro and other explosives.	0 3
415	Glycerin, when imported by manufacturers of explosives, for use in the manufacture thereof in their own factories.	10 % <i>ad val.</i>
416	Torpedoes, fire-crackers, and fireworks of all kinds.	25 % <i>ad val.</i>
417	Fertilisers, compounded or manufactured.	10 % <i>ad val.</i>
418	Lamp wicks.	25 % <i>ad val.</i>
419	Photographic dry plates.	30 % <i>ad val.</i>
<i>Sugar, Syrups, and Molasses.</i>		
435	All sugar above number sixteen, Dutch standard, in colour, and all refined sugars of whatever kinds, grades, or standards.	Per lb. 0 1
436	Sugar, n.e.s., not above number sixteen, Dutch standard, in colour, sugar drainage, or pumpkins drained in transit, mahala or concentrated mahala, tank bottoms and sugar concrete (the usual packages in which imported to be free).	0 0½
437	Glucose or rape sugar, glucose syrup and corn syrup, or any syrups containing any admixture thereof.	0 0½
438	Sugar-candy, brown or white, and confectionery, including sweetened gums, candied peel, and popcorn.	0 0½ and 35 % <i>ad val.</i>
439	Maple sugar and maple syrup.	20 % <i>ad val.</i>
440	Syrups and molasses of all kinds, n.e.s., the product of the sugar cane or beet, n.e.s., and all imitations thereof or substitutes thereof.	Per lb. 0 0½
441	Molasses produced in the process of the manufacture of cane sugar from the juice of the cane without any admixture with any other ingredient, when imported in the original package in which it was placed at the point of production and not afterwards subjected to any process of treating or mixing, the package in which imported, when of wood, to be free.	
	(a) Testing by polariscope 40 degrees or over.	Per gall. 0 1½
	(b) When testing by polariscope less than 40 degrees and not less than 35 degrees.	0 1½
	And in addition thereto, 1 cent per gallon for each degree or fraction of a degree less than 40 degrees.	

## Schedule B.—Free Goods.

No.	Article.
462	Philosophical instruments and apparatus imported for use in universities, schools, and scientific societies.
461	Books on the application of science to industries of all kinds.
466	Books printed by any association for the promotion of science.
475	Models of inventions (but not those which can be fitted for use).
476	Aluminium in ingots, blocks, or bars, strips, sheets, or plates, alumina and chloride of aluminium, or chloraluma, sulphate of alumina and alum cake, and alum in bulk only, ground or unground.
477	Ambergris; ammonia, sulphate of sal ammoniac, and nitrate of ammonia; arsenic; bromine, largely pitch; cambric, cochineal, cyanide of potassium, and cyanogen or compound of bromine and potassium for reducing metals in mining operations; iodine, crude; kroylite or cryolite, mineral; oxalic acid; quinine, salts of; salt-petre; calcareous tufa; alizarine and artificial alizarine; aniline oil, crude; aniline salts and arsenate of aniline; annato, liquid or solid; aniline dyes and coal tar dyes in bulk or packages of not less than one pound weight.
478	Antimony salts; antimony, or regulus of, not ground, pulverised, or otherwise manufactured.
480	Asphalt, or asphaltum; bone pitch, crude only; and resin or rosin in packages of not less than one hundred pounds; and resin oil.
481	Bismuth, metallic, in its natural states; blood albumen and tannic acid.
485	Blast furnace slag.
488	Bones, crude, not manufactured, burned, calcined, ground, or steamed.
490	Boric acid and borax, ground or unground, in bulk of not less than 25 lb.
501	Celluloid, xylonite, or xyolite, in sheets and in lumps, blocks, or balls in the rough.
502	Chloride of lime, in packages of not less than 25 lb. weight; cobalt, ore of; oxide of cobalt, oxide of tin, and oxide of copper; copper, precipitate of, crude; dragon's blood; gypsum, crude (sulphate of lime); lava, unmanufactured; manganese, oxide of; phosphorus; litharge; saffron, saffron cake, safflower, and extract of; sulphate of iron (coppers); sulphate of copper (blue vitriol); sulphur and brimstone, crude or in roll or flower; tartar emetic and grey tartar; cream of tartar in crystals and argol or argols; verdigris, or sub-acetate of copper, dry; zinc, salts of, and tartaric acid crystals.
505	Clays, including China clay, fire-clay, and pipe-clay; gault, miter and sand.
506	Coal, anthracite and anthracite coal dust; coke.
507	Coal and pine pitch, and coal and pine tar of not less than 15 gallons.
510	Crucibles, clay or plumbago.
515	Drugs, crude such as bark, flowers, roots, beans, berries, balsams, bulbs, fruits, insects, grains, gums and gum resins, herbs, leaves, nuts, fruit and stem seeds—which are not edible and which are in a crude state and not advanced in value by refining or grinding or any other process of manufacture and not otherwise provided for; egg yolk; fuller's earth, in bulk only, not prepared for toilet or other purposes; lead, nitrate and acetate of, not ground; litmus and all lichens, prepared or not prepared; musk, in pods or in grain; roots, medicinal, viz.:—alkanet, crude, crushed or ground, acorn, calumba, folie digitalis, gentian, ginseng, jilap, ipocastanea, iris, orris root, liquorice, sarsaparilla, squills, taraxacum, rhubarb, and valerian, unground; vaccine and ivory vaccine points; gum chicle or sappato gum, crude; platinum and black oxide of copper, for use in the manufacture of chlorate; potash, chlorate of, not further prepared than ground, and free from admixture with any other substance; and bacteriological products or serum for subcutaneous injection.
517	Dyeing or tanning articles, in a crude state, used in dyeing or tanning, n.e.s.; berries for dyeing or used for composing dyes; turmeric, nut galls and extracts thereof; lac, crude, seed, button stick, and shell; indigo, indigo paste and extract of, and indigo auxiliary or zinc dust; persis, or extract of archill, and cudbear; terra japonica, gambier or cutch, extract of logwood, fustic, oak and oak bark, and quebracho; emuwood and sumac and extract thereof, tanner's bark, hemlock bark, and oak bark; ground logwood, ground fustic, patent prepared dyes, and ground oak bark; iron liquor, solutions of acetate or nitrate of iron for dyeing and calico printing; madder and munjeet or Indian madder, ground or prepared, and all extracts of; red liquor, a crude acetate of aluminium prepared from pyroligneous acid, for dyeing and calico printing.
520	Fertilisers, uncompound or unmanufactured, including phosphate rock, kainite or German potash salts, German mineral potash, bone dust, bone black, or charred bone and bone ash, fish offal or refuse, guano, and other animal or vegetable manures.

## VICTORIA.

## Classification of Articles in Customs Tariff.

The Board of Trade have received from the Department of Trade and Customs, Melbourne, a copy of Supplement No. 2 to the Customs Tariff Decisions, 1896, in which the following articles are classified as under:—

No.	Description of Articles.	Rate of Duty.
91	<i>Essence</i> —Lemon soluble, "Stevenson and Howells," contains 89.6 per cent. proof spirit.....	12s. per liquid gallon.
191	<i>Glassware</i> —Instruments of glass for testing brine, as glassware not otherwise enumerated.	25 ad val.
	<i>Glu. Marin</i> (pitch).....	Free.
	<i>Medicines</i> , &c.— Analgin and Arconin: are simple chemicals, and if not packed ready for retail sale or consumption, and not recommended.	Free.
285	Anti Streptococcus Serum.....	25 ad val.
285	Anti-Diphtheritic Serum.....	25 ad val.
285	Anti-Syphilitic Serum.....	25 ad val.
	Cale Glycerophosphas. Ingredients in chemical combination not packed ready for retail sale, and not recommended.	Free.
	Carniferin and Ferripyrim: are chemicals, and if not packed ready for retail sale or consumption, and not recommended.	Free.
285	Diuretin, in 1 oz. bottles, a compound not in chemical combination.	25 ad val.
	Ferri Glycerophosphas. Ingredients in chemical combination, and if not packed ready for retail sale or consumption, and not recommended.	Free.
	Jalap in and Lysidine, in 1 oz. bottles, not packed ready for retail sale or consumption, and not recommended.	Free.
	Lactophenin and Trional: are simple chemicals, and if not packed ready for retail sale or consumption, and not recommended.	Free.
	Pepsin Aseptic, in 1 oz. packets. "Parke, Davis and Co."	Free.
386	<i>Milk, Peptonised</i> —"Savory and Moore's," as milk, preserved.	2d. per lb.
	<i>Sheep Dip</i> —"Hatch's" Colonial Glycerin.....	Free.
	<i>Facoleum</i> , composed of vasoline and mineral oil.	Free.

## EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

## THE ADULTERATION OF SUMACH AND THE ESSENTIAL OILS OF LEMONS, &amp;c., IN ITALY.

*Bd. of Trade J., Oct. 1897, 458.*

A report, dated 7th September last, has been received at the Foreign Office from H.M. Consul at Palermo, enclosing translation of an Act which has been recently issued, but, on the above date, had not yet been put into force, concerning the adulteration of sumach and of the essential oils of lemon, &c.

The principal articles of the above Act read as follows:—Whoever manufactures, keeps in stock, or puts on sale essences of "agrumi" (i.e., of the citron family, e.g., essence of lemon, bergamot, &c.), or ground or powdered sumach, mixed with other substances, must indicate clearly the quantity and quality of the added matter, upon the receptacles in which they are contained, upon the way-bills, the invoices, and the registers which refer to the same.

Transgressors will be punished by a fine of from 100 to 500 lire, to which may be added, in case of a repetition of the offence, imprisonment not exceeding one month.

Article 2. Whoever sells essence of "agrumi," or ground or powdered sumach, which is impure, without the indications prescribed in the foregoing paragraph, or without otherwise letting the purchaser of the same know their quality, is punishable by a fine of from 200 to 1,000 lire, and, in the case of a second offence, by imprisonment not exceeding three months.

If the sale is made for foreign shipment the penalty is increased by one-half.

## WARNING TO INTENDING PURCHASERS OF RUBBER FORESTS IN BRAZIL.

*Bd. of Trade J., Oct. 1897, 388.*

The Foreign Office have received a report, dated 28th August last, from Mr. W. A. Churchill, H.M. Consul at Para, stating that he had received a letter from a British firm inquiring as to the possibility of their purchasing rubber forests with a view to successfully exploiting the rubber industry on a large scale.

Mr. Churchill continues as follows:—

"I made the necessary inquiries, and was universally informed that such an enterprise would be followed by at least failure, and that it has been attempted many times by Europeans and Americans, but invariably ended in disaster. I accordingly replied in this sense, and explained the reasons, the principal one being the climate, which in most of the swampy, inundated rubber districts is fatal to white men, besides being injurious to the natives."

H.M. Consul also states that it has come to his knowledge that several magnificent (pestilential) forests of rubber-bearing trees will be offered for sale in England by speculators, and therefore thinks such steps should be taken as may be considered necessary to warn the British public, adding: "I would most decidedly discourage anyone from investing in such an undertaking."

## BRITISH AND GERMAN DRUG TRADE.

*Foreign Office Reps., Annual Series, No. 1977; through Pharm. J.*

The British and German drug trade for 1895 and 1896 is dealt with in a recent report, which gives some very interesting figures tending to prove that, as far as direct trade between the two countries is concerned, Great Britain not only holds the foremost position, but is increasing her export, while that of Germany is decreasing. The exports of drugs and druggists' goods from Great Britain to Germany were 59,179,000 kilos, in 1895, and 61,863,800 in 1896, an increase of 2,384,800 kilos. British imports from Germany, however, during the two years were 42,520,600 kilos, in the former, and 41,791,400 kilos, in the latter year, a decrease of 729,200 kilos.

The German Chemical trade with England has also suffered more or less during the last year; still this branch is one of the most important ones for the trade of both countries. Only a few of the chemicals in which the London market specially participates are dealt with in the report, the first being sulphate of ammonia.

*Sulphate of Ammonia.*

Of the entire German export, 12,651 d.c.,\* 7,236 d.c. came to Great Britain, compared with 15,217 d.c. and 7,317 d.c. in the previous year. Over-production has caused this article to suffer a great fall in price, the English market price of sulphate of ammonia falling from 8*l.* 9*s.* per ton in January to 7*l.* 8*s.* in December 1896, the average price being 7*l.* 18*s.* per ton, as against 9*l.* 15*s.* in 1895, and 13*l.* 3*s.* in 1894.

*Aniline Products.*

The supply of aniline productions by Germany to foreign countries has considerably increased during the past year, though it did not attain the same increase as in 1895 compared with 1894.

*Cochineal.*

Cochineal has, in consequence of over-production, suffered a serious fall in price. The English deliveries in 1896 amounted to 3,275 serons (bales), compared with 2,457 in 1895.

*Glycerin.*

The import of refined glycerin into Germany has increased; 16,444 kilos. were imported in 1896, as against 13,768 in 1895. Of this, Great Britain sent 4,995 kilos. The export of refined glycerin amounted to 26,125 kilos, compared with 18,982 kilos. in 1895. Of this quantity Great Britain imported 5,903 kilos. The prices yield at present to the influence of the American market, but it seems probable that this will cease to be the case, as America will produce sufficient to supply her home demand.

\* Double centner = 100 kilos.

*Sulphate of Copper.*

The prices for sulphate of copper have steadily increased since April 1896, the whole year showing numbers as to the consumption and delivery which have never before been reached. The total deliveries in open market (German) amounted to 217,066 tons in 1896, an increase in the European consumption of 50 per cent. The market opened in January at a price of 40*l.* 11*s.* 3*d.*, reaching its highest point in June, 50*l.* 5*s.*, the concluding price of the year being 49*l.* 10*s.*

## MEXICAN IMPORT OF CHEMICAL PRODUCTS.

*Foreign Office Reps., Annual Series, No. 1985, p. 5 ; through Pharm. J.*

The Mexican import of chemical products amounted to 358,487*l.* in 1896, compared with 304,623*l.* in 1895. A noticeable feature in this branch of trade was the great increase in the importation of paints and colours, which in 1895 only amounted to 27,812*l.*, while in 1896 it represented a value of 64,963*l.*, or more than 130 per cent. difference.

## EXPORT OF CHILE FROM MEXICO.

*Ibid., p. 9.*

The export of chile from Mexico during 1896 exceeded by nearly 1,000,000 lb. that of the preceding year. Hitherto it has been used almost exclusively as a chewing gum, but experiments are being made to ascertain if it cannot be used for certain purposes as a substitute for india-rubber.

## NITRATE OF SODA.

*Foreign Office Reps., Annual Series, No. 1994, p. 8 ; through Pharm. J.*

Nitrate of soda was introduced into the port of Antwerp during 1896 to the total amount of 133,500 tons, as against 118,370 tons in 1895. Other fertilisers imported were Peruvian guano, 20,000 tons; phosphates, 12,000 tons; sulphate of ammonium, 24,000 tons.

## CHEMICALS IN MOROCCO.

*Foreign Office Reps., Annual Series, No. 1995, p. 21 ; through Pharm. J.*

Chemicals to the value of 1,773*l.* (1,303 cwt.) were imported at Larache (Morocco) in 1896, as against 1,174*l.* (746 cwt.) in the previous year.

## THE WORLD'S PRODUCTION OF NICKEL.

*Eng. and Mining J., Oct. 16, 1897, 452.*

The production of metallic nickel, including the metallic contents of that sold in the form of oxide, sulphide, sulphate, &c., in 1894-1896 was as follows (the figures being metric tons) :—

Year.	Prussia.	From New Caledonia Ore smelted in France and England	Total New Caledonia.	Canada.	Norway.	World's Total.
1894	512	1,600	2,112	2,226	90	1,798
1895	618	1,850	2,468	1,764	90	1,402
1896	822	2,150	2,972	1,541	90	1,603

## FOREIGN COMPETITION IN THE COLONIES.

*Chem. and Druggist, Oct. 2, 1897, 560.*

We subjoin a few more abstracts of pharmaceutical interest from the recent Blue-book on foreign goods in the colonies.

*Newfoundland.*

The Newfoundland report has been compiled from official statistics and information obtained from merchants.

It is stated that only in a few classes of goods, among which are *Medicines*, the United States are superseding Britain. The medicines imported are chiefly proprietary articles. In *Soaps*, America is losing ground. In 1881, Newfoundland took two-thirds of its soap from the United States, in 1894 hardly any. The same is the case in *Painters' colours*. Here are the figures.

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
<i>Medicines</i> —total import .....	32,648	50,329	45,835
Of which from U.S.A. ....	2,125	3,683	10,775
<i>Soap</i> —total import .....	31,475	22,191	38,290
Of which from U.S.A. ....	12,250	8,884	2,360

*The British West Indies.**Bahamas.*

The Bahamians, says Sir W. H. Smith, buy 75 per cent. of their requirements in the United States, and the proportion is increasing.

Here are some plain statements :—

"Every merchant of the colony has some anecdote to relate as to the mode in which his business has been injured by the indifference of the British merchants.

"Attempts have been made to open a trade in English goods with Cuba. Those who have tried it, however, found that the English merchants would not take the trouble to suit the goods to the requirements of the special market, and the attempts have failed.

"The English carrying trade to many places on the Spanish Main, and in Hayti and Porto Rico, has been driven out by the German steam lines, which are worked most economically. The whole of this carrying trade was British, but it has gone in consequence of the German lines paying close attention to the convenience of shippers."

*Bermuda.*

Most of the trade of Bermuda is with the United States. The tendency is a natural one, on account of the geographical position of the islands, and is increased by the rapid and frequent steam communication, and the frequency with which American commercial travellers visit Bermuda.

*Medicines* (principally patents) are chiefly imported from U.S.A.

	1884.	1889.	1894.
	£	£	£
The total value was.....	2,128	3,186	3,630
Of which from U.S.A. ....	1,399	2,486	2,426

*Soap*.—Mostly from the United States. "Premiums" are offered to purchasers of certain quantities of soap. American soap is put up in small coloured-paper packets, which makes it attractive; while soap imported from the United Kingdom is put up in long bars, and, although of better quality, the absence of "premiums" causes it to be in less demand.

*British Honduras.*

The British Honduras Report is, as all such reports should be, the work of commercial experts appointed by the Governor of the Colony. The imports of foreign goods, other than provisions, are small, and mostly find a market because the goods are low in price. The imports or *Drugs and Chemicals* were :—

	1884.	1889.	1894.
	Dols.	Dols.	Dols.
From United Kingdom .....	2,206	1,187	1,014
" United States.....	1,361	1,933	1,076
" other parts .....	105	52	39
<i>Perfumery</i> :			
From United Kingdom ...	625	1,055	438
" other parts .....	1,118	1,289	1,036

*Soap*, nearly all British, is imported to the extent of about 6,000*l.* a year.

*Jamaica.*

The following figures relate to the imports of certain pharmaceutical goods in 1894 :—

*Glass Bottles*.—6,055*l.*, of which 2,613*l.* from U.S.A.

*Instruments (Surgical, &c.).*—727l., of which 238l. from U.S.A.

*Soap.*—22,381l., of which 380l. from U.S.A.

*Perfumery.*—5,664l., of which 1,975l. foreign.

Where foreign goods compete successfully with British, it is because the foreign houses pay more attention to local requirements, give superior finish, lower price, more careful packing without any special charge therefor, cheaper freights, and more rapid communication.

In cordage, twine, certain classes of cotton goods, hardware, and cutlery, the United States have gained ground on Britain. The trade statistics show a large increase of imports from the United States and Germany, but this increase is much more apparent than real, because the tendency throughout the West Indies is to use New York as a port of transit, although much of the merchandise carried through that port is not American. The increase of imports from Germany (90l. in 1884, 21,966l. in 1891), is due to the establishment of a direct steamship line, and to the British Merchandise Marks Act.

The presence in Jamaica of many German business houses, the cheapness of labour in Germany, the special efforts made by the German Government to extend its foreign trade also assist. The bulk of the Jamaican population want cheap goods, irrespective of quality.

#### Other West Indian Islands.

*Medicines.*—Most of the foreign imports are American patents. All other drugs come from Britain. The following are the principal patents used:—

American:—Lung-balsam, 8d. per bottle of 4 oz.; Pymy pectoral, 8d. per bottle; Canadian healing oil, 8d. per bottle; Pain-killer, 6d. per 2-oz. bottle; Condition-powders, 7d. per pack; Ross's pills, 3l. 6s. 8d. per gross; Williams's pink pills, 4l. per gross.

French:—Vinaigre des 4 voleurs, 1d. per oz.; Aleolat valvar blanc, 1d. per oz.; Eau des Carmes or Eau Mclisse, 1d. per oz.; Elixir antilaigreux, 1s. 8d. per 1-pint bottle; Boule des Mars, 9d. per oz.; Baume tranquille, 1d. per oz.; Syrop de flore, 1s. a bottle; Syrop de choux, 1s. 2d. a bottle; Syrop de nafs, 1s. 1d. a bottle.

All these prices are in bond, delivered West Indian Islands.

*Perfumery.*—The bulk comes from Britain; "Florida-water" from U.S.A. and Germany.

The following figures represent the approximate imports of medicines, perfumes, and soap in other West Indian Islands in 1894:—

	Medicines.		Perfume.		Soaps.	
	Total.	Including Foreign.	Total.	Including Foreign.	Total.	Including Foreign.
Dominica, Antigua, Montserrat, &c.	£ 2,000	£ 500	£ ..	£ ..	£ 3,000	£ 350
Windward Islands ..	800	100	..	..	1,450	140
Barbados ..	5,700	1,500	2,650	1,250	..	..
Trinidad ..	10,000	3,500	..	..	..	..

There appears to be little or no displacement of trade in these articles from Britain to foreign countries. Where there is, the reasons are better packing, better finish, more suitable patterns.

#### MINES AND QUARRIES. MINERAL STATISTICS OF THE UNITED KINGDOM OF GREAT BRITAIN AND IRELAND, WITH THE ISLE OF MAN, FOR THE YEAR 1896. (C.—8564.)

This is an annual statement prepared by the direction of the Secretary of State for the Home Department. In the introduction it is stated that the present volume contains an account of the quantity and value of the minerals obtained from mines, quarries, brineworks, &c. in the United Kingdom. In an appendix is shown the production of minerals in the British Colonies and Possessions compiled from official reports.

#### Mineral Produce of the United Kingdom

Description of Mineral.	1895.		1896.	
	Quantity.	Value.	Quantity.	Value.

#### AMERICAN COTTON-SEED OIL IN MARSEILLES.

U.S. Cons. Reps. 1897, 54, [202], 430—432.

The supply of sesame, peanut, poppy, linseed, castor, and cotton seed from India having been entirely cut off owing to the bubonic plague, there is a scarcity of seed in the market here for the manufacture of oils, and American cotton-seed oil is now being largely used by soap manufacturers, &c., owing to the higher prices of peanut, olive, and cocoa-nut oils. The cheapest grade of olive oil for machinery purposes is quoted at 54 to 64 fr. per 100 kilos. (reductions made at the rate of 3½ kilos. to the gallon or 32 galls. to the 100 kilos.), or 34 to 39 c. per gallon; and peanut oil at 46 fr. per 100 kilos., or 28 c. per gallon; whilst American cotton-seed oil is selling at 40 fr. per kilos.,

r 24 cents per gallon. The following table shows the receipts of American cotton-seed oil at Mar-seilles during the past seven years:—

Year.	Quantity.	Year.	Quantity.
	Barrels.		Barrels.
1890	66,024	1894	12,550
1891	56,392	1895	5,528
1892	16,798	1896	112,927
1893	137,60		

During the year 1896 the total receipts from all other countries than the United States were only 11,335 barrels, 11,109 of which came from British provinces.

The following quotations of the relative prices of American and English cotton-seed oils, during the past seven years, indicate that the latter is inferior in quality to the former:—

Price per Gallon.		Price per Gallon.	
Year.	American Oil.	Year.	English Oil.
	Cents.		Cents.
1890	35	1894	35½
1891	34½	1895	29½
1892	32	1896	26½
1893	43		

—A. S.

### GENERAL TRADE NOTES.

#### THE PRODUCTION OF COCA AND COCAINE IN PERU.

*Bd. of Trade J., Oct. 1897, 476.*

The *Economista*, of Lima, in an article on this subject, says that 20 years ago coca was only cultivated in a few provinces which were most favoured by reason of climate and cheap labour. Since then the industry has rapidly developed. In the province of Otuzco, the most important district for the production of coca in Northern Peru, the number of plants is computed at 2,700,000, and the annual production amounts to 4,700 quintals. It is worth remarking that most of the plant's in this province have not yet attained their full growth, and that in a few years the production will increase probably to 10,000 to 12,000 quintals.

The coca is sold by two houses in Truxillo, which dispose of the product to the cocaine manufacturers in Lima. As they exercise a sort of monopoly the price varies from time to time, the Lima manufacturers sometimes being obliged to pay as much as 32 sols (1 sol equals 2s.) per quintal for raw coca delivered free on board at Salaverry. The proprietors of the haciendas of Huayabamba and of Cayanchal are planning to establish cocaine factories in the neighbourhood of their own plantations, and the competition thus engendered will probably lower the price.

In order that the coca may be cultivated under the most favourable conditions it is necessary that the temperature should rarely fall below 24° C., and it should be about 30°. As for the altitude of the plantations, they are usually situated at a height of 3,000 to 4,000 ft. above sea-level. There are very few plants grown at a height of 5,000 ft., and the coca under these conditions is usually of an inferior quality. The quality of the coca varies also according to the soil; that obtained from a dry soil is better than that grown in damp ground. It is for this reason, for instance, that the coca of Chuquillanqui, though sometimes attaining a height of 10 ft., does not by any means possess the strength and the aroma of that which is grown in other parts of Peru. The shipments of coca from the ports of Huanchaco and Salaverry, which so far as the foreign trade is concerned are coincident with all Peru, were as follows for the years 1894 and 1895.

	Huanchaco.	Salaverry.
	Kilos.	Kilos.
1894	736	611,153
1895	85,716	155,006

#### THE ALGERIAN PHOSPHATE DEPOSITS.

*Eng. and Mining J., Oct. 9, 1897, 427.*

M. Chateau publishes, in the *Memoirs* of the French Society of Civil Engineers for August 1897, an important monograph on the phosphate deposits of Constantine and Algeria. The paper covers 118 pages, and contains a historical account of the discovery of sedimentary phosphates on the high tableland of Algeria, with a description of the geological structure, the nature of the phosphates, and the theory of their formation. The various deposits are described in detail, and particulars are given of the cost of production, the exports, the future of the industry, and the legislative enactments relating to it.

#### CADMIUM.

*Eng. and Mining J., Oct. 9, 1897, 421.*

The increase in the demand for cadmium and the shortage in the supply still continue, notwithstanding a little more is being made in Upper Silesia (which is, indeed, practically the only district where cadmium is produced). The Upper Silesian production in the first quarter of the current year was 3,326 kilos. (valued at 11·844 marks per kilo.), against 3,256 kilos. (valued at 10·261 marks per kilo.) in the last quarter of 1896, and 2,436 kilos. (valued at 5·380 marks per kilo.) in the first quarter of 1896. At present, it is said, the metal is lacking entirely, and urgent demands for it cannot be satisfied. The cause for this peculiar situation is unknown. If the new demand proves to be permanent, however, there should be no difficulty in meeting it, since most of the Upper Silesian ore is cadmium-bearing, and the metal can be recovered without difficulty as a by-product at works where the distillation muffles are equipped with the Dagner or Kleeman condensers, and provision is made to collect the escaping fume. With such an arrangement the cadmium fume is deposited especially in the first part of the common fine, furnishing a product which, if saved separately, is rich enough for treatment to recover the cadmium. At present this is done at only two or three works, and others probably with be slow to make the necessary arrangements until it has been demonstrated that the increased demand for cadmium is likely to be permanent, for after all the present business does not amount to much.

#### ANNUAL MEETING OF THE GERMAN CHEMICAL INDUSTRIAL SOCIETY.

*Chem. and Druggist, Oct. 9, 1897, 573.*

THE Annual Congress of the German Society for the Protection of the Interests of Chemical Industry was held at Baden-Baden last week. In submitting his usual report of the condition of the chemical industry of the country, the President, Dr. Holtz, stated that in 1896 the output of chemical products increased by 8·7 per cent., the average number of workmen employed by 5·2 per cent., and the total amount paid in wages from 103·4 to 113·7 millions of marks, or from 894·16 to 966·58 marks per head. The exports increased by 6·5 per cent. in value, and by 13 per cent. in quantity. As a consequence of the general fall in prices, there was a reduction in the average net profits (as shown in the reports of the principal chemical companies) from 12·71 to 12·3 per cent. Another matter which came up for discussion, and gave rise to an interesting debate, was the question of whether it was desirable that a State examination should be instituted for technical chemists. This is a matter that has of late been widely discussed in the German technical press. Ultimately, a set of rules was adopted, declaring in substance that although German chemical industry was much interested in the most thorough training of technical chemists, they were not prepared to indicate any special means of arriving at this object, espe-

cially in consideration of the fact that effective measures are shortly to be taken to carry out the recommendations of the Union of Directors of Laboratories of German Universities in connection with this matter, and that the Imperial Government has announced that a Commission will be constituted at the end of October to inquire into the matter. The Society therefore intend at present to maintain a neutral attitude. The Commission of inquiry referred to will consist of representatives of the German Universities, of the technical high schools, and of the chemical industry. Dr. Martins read a report on the projected participation of German chemical industry at the next Paris World's Fair. It is suggested that the industry should exhibit as one collective whole, the objects shown being representative of every branch of the industry, because the room set apart for this section is insufficient to enable all firms to have suitable individual exhibits. This plan of the collective exhibit is strongly supported by the German Imperial Commissioner for the Paris Exhibition, Mr. Richter. It was then decided that the matter should be taken in hand by several sub-committees, each representing a special branch of chemistry. Another matter of importance that was discussed was the proposed central bureau for the preparation of a commercial treaty. The new German Customs tariff is in preparation, and this will probably lead to the collection of new commercial treaties with various countries. The German Government intend to consult all branches of national industry on this subject, and the Society adopted a resolution hoping that means would be found to avoid disension among the various industrial branches.

#### INLAND REVENUE STATISTICS.

*Chem. and Druggist*, Oct. 2, 1897, 554.

The methylation of spirits is an increasing business. In the year ending March 31, 1896, the quantity methylated in the United Kingdom reached 3,930,972 gals.: in the year ending last March the quantity was 4,149,310, an increase of 218,338 gals. There were 25 makers of methylated spirits licensed in 1896, and 13,891 licensed retailers.

At the Inland Revenue branch of the Government Laboratory, a total of 61,664 samples were examined during the year ended March 31 last. This was an increase of nearly 10,000 samples over the previous year. There were 28,875 samples of beer, and 13,875 of tobacco, tested during the year. Only 60 samples were referred to the laboratory under the Sale of Food and Drugs Act (82 the previous year). The exportation of tinctures, &c., under the drawback system is still progressing. The number of samples tested last year for this drawback was 8,182, against 7,000 the year previously.

The number of chemists who paid licenses for stills in 1896 was 703 in England, 115 in Scotland, and 25 in Ireland.

#### CLOVES AND CAFFEINE IN FRANCE.

*Chem. and Druggist*, Oct. 9, 1897, 575.

At the last meeting of the Paris Syndical Chamber of Chemical Products, M. Adrian mentioned that the Exeise authorities had given distillers facilities for preparing oil of cloves, which was formerly not permitted. The cloves are admitted duty free, and, after having been used for preparing the oil, are burnt in the presence of an Exeise officer. M. Adrian thinks the same favour might be accorded to chemists for the preparation of certain alkaloids, and he especially referred to caffeine as being one of the most important on account of its increased use.

#### THE PRODUCTION OF SALT.

*J. Soc. Arts*, 1897, 1114.

The quantity value of salt produced in the United Kingdom, and used in brine during the five years ended 1895, are as follows:—In 1891, 2,043,571 tons, valued at 976,824l.; 1892, 1,956,524 tons, value 861,401l.; 1893, 1,924,029 tons and 735,222l.; 1894, 2,235,912 tons and 763,629l.; and 1895, 2,173,253 tons and 709,751l. The corresponding figures for 1896 are not yet available. In commenting upon the returns of salt production in the

United Kingdom, it is stated in the report of the Salt Chamber of Commerce for 1896, that the ammonia soda process has, by its increase, deprived of some portion of their previous markets those who produce salt for sale. The total trade of the United Kingdom exhibits an increase, the slight relapse in 1896 being due to exceptional freight circumstances. The export and coastwise figure, taken together, of the last five years are as follows:—In 1892, 958,306 tons; 1893, 919,785; 1894, 1,006,483; 1895, 1,080,601; and 1896, 1,022,617 tons. No fresh discovery of rock salt or brine has occurred in this period, except the interception of salt in the Isle of Man during some borings for coal; nor has there been in any part of the world any noteworthy expansion of the existing manufacture. Occasional efforts have been made in South America and Spain, and elsewhere, to utilise long known deposits of salt which are hopelessly remote from railway or ocean, from labour or fuel, or otherwise devoid of commercial importance. In the production of the United Kingdom there has been little change, except some readjustment to topographical and other economic advantages. All the salt districts of the country, especially the most advantageous, have been developed far in excess of either their respective local or foreign demand. The natural result has ensued: prices no longer, says the report of the Salt Chamber, offer any inducement to the enterprise of increasing the plethora. Germany having a few years ago reached the limits of her own consumption, has been pushing the salt into the markets of neighbouring countries, and with less success into more remote parts of the world. Her strength lies in the facilities and cheapness of her inland navigation and ports of shipment. In the United States the inflation of native production, caused by the indiscretion of English manufacturers in 1889 and 1890, has been partially corrected, but reports still show considerable struggles between the chief districts producing in excess of demand. The Red Sea has provided more salt for India. It is of inferior quality, but, like the Hawburg article, is mixed with English salt, and goes into consumption at a lower price. When Eastern freight, and consequently the price of English salt, is at a normal level, the market of these lower grades is limited. The Indian Government has powers under Adulteration Acts to restrain this mixture, but has not yet seen fit to exercise them.

#### THE CHILEAN NITRATE INDUSTRY.

*Eng. and Mining J.*, Sept. 25, 1897, 371.

Senor Don Alberto Herrman, in the *Boletín de la Sociedad Nacional de Minería*, states that the cost of production at three nitrate mines is as follows:—

	San Jorge.	Puntuchara.	San Pablo.
Extraction of the caliche.	Cents. 27.68	Cents. 32.47	Cents. 50.40
Carting.	12.90	23.46	21.26
Dressing.	32.08	37.62	48.80
General costs.	7.22	9.01	12.87
Various.	0.17	1.32	..
Total .....	80.05	103.88	142.42

The Chilean nitrate industry has to contend against the competition of artificial soda manures and sulphate of ammonium, the output of which rapidly increases year by year, the discovery of nitrate deposits in other parts of the world, and the competition of guanac rich in nitrogen, phosphoric acid, and potash, like those recently discovered in the island of Corcovado, Peru. Lately, as is well known, the Chilean industry has been suffering a serious depression. The continuance of this is having an alarming effect on both the revenue and trade of Chile. Hundreds of workmen have been thrown out of employment in the nitrate districts, and they are being brought south, where, at the present time, there is no demand for labour. Realising the importance of revivifying the industry, the Government has joined the Permanent Nitrate Committee in the propaganda carried on by the latter to introduce the product in new markets. The ministry promises at least 75,000 dobs., which

may possibly be increased to 200,000 dols., toward this object. The duty has been taken off some sample cargoes which have been sent to China and Japan, while special agents have been sent to the United States with a view of increasing the use of nitrate in this country.

#### PETROLEUM IN TEXAS.

*Eng. and Mining J., Oct. 2, 1897, 399.*

Petroleum was discovered early this year at Corsicana, Texas, at a depth of 1,040 ft. At this horizon there is a bluish-sandy shale about 20 ft. thick, which is saturated with petroleum. There is no rock, either above or below, the drill passing down the whole way through a hard clay. The Texas Petroleum Company, organised six months ago, has three flowing wells, the latest of which is said to be producing about 20 barrels per day. The Corsicana Oil Development Company has a well which is flowing 25 barrels. A correspondent of the *Pittsburg Times*, who has visited the district, states that according to the testimony of those familiar with the products of the different fields, Texas oil is better than the Ohio oil, but not as good as that found in Pennsylvania. It most resembles that produced at Neosho, Kansas. Its flow is like that of the wells in the Bradford field. An analysis of the oil showed about 90 per cent. of volatile matter and 10 per cent. of residuum. As compared with other oils, results are as follows:—

Crude Oil from	Specific Gravity at 17° C.	Boiled at 2° C.	Cane over under 150° C.	Between 150 and 300° C.	Over 305° C.
			Per Cent.	Per Cent.	Per Cent.
Texas-Corsicana	821	80	34.6	40	15.8
Pennsylvania ..	818	82	21.0	38	19.7
Galicia .....	824	90	26.5	47	26.5
Baku .....	850	91	23.0	38	39.0
Alsace .....	907	133	3.0	59	47.0
Hanover .....	899	179	..	32	68.0

The line of development at present is about 1½ miles long and covers an area of about 150 acres. It costs about 1,500 dols. to put down a well, and the royalty varies from one-eighth to one-tenth.

The present production is used exclusively for fuel. Some is consumed at the wells and in the local manufacturing establishments, and the rest goes to Dallas, Houston, Austin, &c. In the towns named it is being used in making illuminating gas. It is delivered in Corsicana for fuel at 75 cents a barrel. At present there is a market for all that is produced, but if the continued development increases the production, a larger market must be had, or a refinery established.

#### SALTPETRE IN SPAIN.

*Chem. Trade J., Oct. 2, 1897, 215.*

Saltpetre was at one time imported exclusively from England to Oporto, and for a long time after Germany began to compete, preference was given, even at a higher price, to the British article. Germany has, however, considerably improved her manufacture, and, owing to lower prices, is supplanting some English makes which were well known here. German competition is assisted by better terms, *i.e.*, longer credits than those granted by English firms, and also better terms are allowed to the local agents, who thus have a greater interest in pushing the products of that country.

#### MANUFACTURE OF STARCH.

*Chem. Trade J., Oct. 2, 1897, 215.*

In spite of the dearth of the raw material on account of the famine in British India, the year 1896 was not an unfavourable one for Belgian rice starch manufacturers. The exports of starch and starch products of home manufacture amounted to 6,329 tons.

#### CITRIC ACID.

*Chem. Trade J., Oct. 2, 1897, 215.*

A factory for the manufacture of citric acid and oil of lemon was established at San Diego during 1896. It takes

from four to six weeks to condense the juice of 60 to 70 lb. of lemons into 1 lb. of acid. The factory employs seven hands, has steam works, and a capacity for 40,000 lemons a week; only culls are used. The same company also makes oil of lemon.

#### CANAIGRE IN CALIFORNIA.

*Chem. Trade J., Oct. 2, 1897, 211.*

Canagire is the American corruption of the Spanish "cana agria," sour cane. It is also called "Yerba-Colorado" in Mexico, localisms being "red dock," "tanner's dock," and "wild rhubarb." The best way to propagate the plant is by use of small roots rather than by seed. About 1,000 lb. of tubers will plant an acre, and October and November are the best months for putting in the crop; though where irrigation can be practised, planting may be done at any time. The value of canagire as a tanning agent, either alone or in connection with other tannins, has been proved beyond question. For light leather it gives great tensile strength, and is far better for split leather than gambier, oak, or hemlock. It is a quick tanner, and the yellow colour absorbed by the hide in the process of tanning is considered highly desirable for certain leathers. The sliced and dried tubers, containing an average of 30 per cent. of tannic acid, are worth from 8*l.* to 9*l.* per ton. A yield of from 7 to 10 tons per acre would give 2½ to 3½ tons of the dried product, for which there is a constant demand in Europe and America. Inasmuch as the plant grows wild in this vicinity, and the seed roots are readily obtained, the industry commends itself to the farmer of small means, as it is harvested in such a short period after planting.

A great deal of interest is being taken in the Los Angeles district in the cultivation of canagire. It was stated in the *Californian* press in February last, that a syndicate of English and American capitalists has purchased 22,000 acres about 50 miles east of this city for 100,000*l.*, for the purpose of cultivating canagire. The agent for the San Francisco Savings Union (the vendors) stated that the purchasers, the Anglo-American Canagire Co., consist of an American and an English syndicate; that the American syndicate is taking over the land, and the English syndicate is interested only in the product. The vendors acquired the property under foreclosure, and are selling at cost price. The company is planting 8,000 acres this season.

#### CHEMICAL WORKS IN SWEDEN.

*Chem. Zeit.; through Eng. and Mining J., Oct. 2, 1897, 395.*

The manufacture of sulphuric acid in Sweden amounts to about 35,000 tons of chamber acid per annum. The greater part of this production is used for the manufacture of superphosphates. The principal producers are the Joint Stock Company, of Stockholm, and the Scandinavian Joint Stock Superphosphate and Sulphuric Acid Manufacturing Company, of Helsingborg. This latter is the most important one of the kind in Scandinavia. It produces annually about 18,000 tons of chamber acid and about 30,000 tons of superphosphate. It is the only concern, also, in any of the Scandinavian countries that produces the double superphosphate containing as much as 45 per cent. of soluble phosphoric acid.

Sulphuric acid is very largely used in Sweden for the manufacture of sulphate of copper. The "Stora Kopparbergs Bergslags Actiebolag," the works of which are at Falun, produces annually 1,500 tons of sulphate of copper. This company, which possesses the celebrated Falun copper mine, and has a capital of 12,650,000 frs., is the most important in Sweden, and produces, besides sulphate of copper, 50,000 tons of cast iron, 43,000 tons of manufactured iron and rolled and forged steel, 7,000 tons of Thomas slag, 6,000 tons of paper, 1,000 tons of red mineral paint, 2,000 tons of sulphuric acid, 350 kilos. of silver, and 100 kilos. of gold per annum.

#### CHEMICAL INDUSTRY IN THE TRANSVAAL.

*C. Butters. Proc. Chem. and Metall. Soc. of S. Africa, July 17, 1897, 3—10.*

Copper has been produced at the Willows and the Albert silver mines, and silver-lead at the Transvaal silver

mines, but the ores are not rich enough to stand the excessive cost of production in this district. There is one sulphuric acid works, producing an acid of low commercial strength, but the manufacture is not firmly established, owing to the small demand for the product, and in spite of a protective import duty of 1d. per lb. Dynamite is not made locally, but its manufacture is strongly advocated (of low grade) for blasting purposes. Glass is now being made at the Lewis and Marks distillery in Pretoria. Coke is being prepared, but although duly improving in quality, it is not yet sufficiently good for use in the iron and steel industries. The author is sanguine as to the ultimate success of this manufacture, as well as of the ore of pig-iron and steel. At present the local coke has to be mixed with from one-third to one-half of foreign coke for blast-furnace purposes; it contains about 17 per cent. of ash, as against 11 per cent. in English coke. Although at present the price is abnormally high, there is no reason why it should not be sold presently at from 2l. 10s. to 3l. per ton. The coal supply is practically inexhaustible, and is essential to the working of gold. Methods of handling the coal are imperfect, and it is still impossible to buy from any colliery an even grade of coal. The percentage of ash in the steam coal ranges from 20 to 25 per cent.; that in smithy coal averages 10 per cent. Agriculture is still in a primitive state. Galena occurs abundantly, some samples containing 80 per cent. of lead. The extraction is carried on locally, but it is restricted, owing to the limited demand for the metal. The industry is protected by an import tax of 3d. per lb.

The main industry, however, is that of gold extraction. Here cyanide treatment is slowly but surely replacing chlorination everywhere for the treatment of slimes. The author believes that the next development will lie in the direction of stamping with a dilute solution of cyanide instead of with water, no water-washes being thrown away. With very poor ores, preliminary amalgamation could then be dispensed with, any free gold present being caught in the concentrates and washed down over a single plate after cyaniding. Such a method, in conjunction with electrolytic precipitation, would form a strong rival to dry crushing processes; especially as with pyritous ores the material must be crushed sufficiently fine to pass a 200- to 400-mesh screen. The African Gold Recovery Co. tried a similar system in 1892, but failed to work it out, owing to the difficulty (since surmounted) of separating the liquid from the pulp.

—W. G. M.

#### PRODUCTION OF METALS IN BRITISH COLUMBIA.

*Eng. and Mining J., Oct. 16, 1897, 451.*

It was not very long ago that the entire mineral product of British Columbia came to the United States in the form of ore. Smelting works were erected in the province a little later, but the silver-lead and the copper matte were still sent to the United States for refining and further reduction respectively. Now, however, British Columbia is beginning to turn out its product in a higher state of completion. The Trail Creek works have installed a refinery, and are now shipping gold in fine bars, while the Hall Mines, Ltd. (Silver King mine), is converting its product into blister copper, which is going directly to Wales. Incidentally it may be remarked that this company has one of the largest smelting furnaces in operation on this continent. With the entrance of Vivian and Sons into the British Columbia ore market, and a freight rate of only 8.50 dols. per ton from Vancouver to Swansea, American ore buyers will have to look sharply to the business.

#### EXPORTS OF TINCTURES IN BOND.

*Chem. and Druggist, Oct. 23, 1897, 671.*

An Inland Revenue order (No. 15, Oct. 7, 1897) has been issued, in which further concessions are made for the exportation of tinctures, medicinal spirits, flavouring essences, and perfumes. The condition allowing essences to be packed in 1-gal. cases, when in bottles not exceeding 4 oz. each, has now been extended to medicinal spirits, but not less than 2 liquid gals. are to be regarded as a legal quantity for exportation in one consignment. Medicinal

spirits, essences, and perfumes may be packed in the same case, when so desired, if packed in separate internal packages. It has been made permissible to export 10 gals. (formerly 5) of medicinal spirit or essence in a jar covered with wickerwork. An important concession is the withdrawal of the regulations which prescribed the minimum and progressive sizes of bottles of perfumed spirits, bottles of any size being not allowed, subject to existing conditions as regards internal packages. Non-dutiable goods may also be packed in with duty paid, provided that they are placed in an internal package marked "Free goods."

#### BOARD OF TRADE RETURNS.

##### SUMMARY OF IMPORTS.

Caoutchouc..... Value £	..	..	99,569	112,486
Cement..... Tons	34,898	32,134	55,376	55,464
Products of coal Value £	..	..	118,971	103,119
Earthenware ....	..	..	137,646	126,111
Stoneware..... "	..	..	17,238	13,332
Glass:—				
Plate..... Sq. Ft.	109,823	133,902	7,148	7,291
Flint..... Cwt.	9,421	7,822	19,400	19,069
Bottles..... "	69,246	61,473	33,971	30,213
Other kinds....	20,351	19,348	15,515	13,807
Leather:—				
Unwrought ....	12,304	13,043	109,700	106,949
Wrought..... Value £	..	..	44,751	33,531
Seed oil..... Tons	5,186	3,417	93,399	62,332
Floorcloth..... Sq. Yds.	1,745,700	1,664,700	74,508	75,787
Painters' materials Val. £	..	..	130,924	118,041
Paper..... Cwt.	87,779	89,354	137,227	118,751
Rags..... Tons	4,683	4,459	27,063	23,598
Soap..... Cwt.	46,976	60,795	52,362	61,309
Total value .....	..	..	2,670,516	2,525,220

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

- 21,665. F. L. Ball. See Class II.
- 21,757. H. W. Jarvis. Improvements in the construction of evaporative condensers for steam or other gases. Sept. 22.
- 21,989. W. D. Cliff and The Leeds Fireclay Company, Ltd. Improvements in or in connection with inclined retorts. Sept. 25.
- 22,020. H. Higgins. Improvements in or relating to vacuum apparatus for evaporation. Sept. 25.
- 22,026. A. W. Stokes and R. A. Lister and Co., Ltd. Improvements in apparatus for automatically measuring off quantities of liquid specially applicable for testing the amount of fat in milk. Sept. 25.

22,027. A. N. Stokes and R. A. Lister and Co., Ltd. Improvements in apparatus for testing the acidity of milk and other liquids. Sept. 25.

22,046. J. Y. Johnson.—From H. K. Mulford, United States. Improvements in machines for compressing powdered materials into tablets. Sept. 25.

22,066. J. Dymond. Improvements in or relating to gas producers. Sept. 25.

22,141. P. F. C. Willecox, H. W. Willecox, and R. J. N. Willecox. Improvements in and relating to apparatus for heating or evaporating liquids by means of steam. Sept. 25.

22,236. J. D. Darling and C. L. Harrison. Improvements in porous diaphragms for electrolytic apparatus. Complete Specification. Sept. 28.

22,704. Sir C. S. Forbes, Bart. Improvements in or connected with hot water heating and drying apparatus. Oct. 4.

22,705. Sir C. S. Forbes, Bart. Improvements in apparatus for condensing steam and vapour, refrigerating liquids and the like. Oct. 4.

22,777. P. R. J. Willis.—From R. McCoy, United States. Improved receptacle for shipping chemicals and like substances. Oct. 5.

22,779. W. Dalton. Improved scientific sanitary filter. Oct. 5.

22,816. J. V. Skoglund. Improvements in nitric acid condensers. Oct. 5.

22,902. J. Kippax. An improved apparatus for injecting anti-erastating fluids. Oct. 6.

22,921. W. Whittaker. Improvements in and relating to mechanical stokers. Oct. 6.

22,940. W. Defries. Improvements in and relating to destructor furnaces. Oct. 6.

22,958. L. H. von Gehlen. Improvements in and relating to air compressors. Complete Specification. Oct. 6.

22,965. D. Cameron, F. J. Commin, and A. J. Martin. Improvements in apparatus for the treatment of sewage or other liquids. Oct. 6.

22,969. A. Brunel. Improvements in apparatus for pasteurizing liquids. Oct. 6.

23,054. H. Higgins. Improvements in or relating to the maintenance and regulation of heat in distillation, refining, chemical manufacturing processes, and the like. Oct. 7.

23,110. H. S. Maxini. Improvements in and relating to apparatus for superheating steam. Oct. 8.

23,178. A. J. Bell and P. A. G. Bell. Improvements in apparatus for the filtration of water, sewage, and other fluids. Oct. 9.

23,195. T. H. Copley. See Class VII.

23,312. F. Arenas. Improvements in apparatus for indicating and recording when the temperature exceeds or falls below predetermined limits. Oct. 11.

23,339. P. R. Allen and J. B. Chadwick. Improvements in or relating to apparatus for evaporating or concentrating liquids. Oct. 11.

23,722. H. Boig. Improvements in refrigerating apparatus. Oct. 14.

23,724. J. B. Hilliard. Improvements in apparatus and process for treating spirits and other fluids. Oct. 15.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1896.

23,792. R. Thiel. Closing device for receptacles for sterilising. Oct. 20.

25,612. C. G. J. Moller. Apparatus for drying granular and other material. Oct. 13.

25,842. J. G. Chamberlain and J. Weddell. Evaporative surface condenser. Oct. 6.

26,112. J. Critchlow and T. Shore. Filter presses. Oct. 6.

26,441. E. C. Weedon. Means for determining the expansion of solids. Oct. 20.

26,937. J. W. Hall. Regenerative furnaces. Oct. 6.

27,494. E. Riepe and G. Oppermann. Regenerative furnaces. Oct. 13.

28,893. G. Nayler and A. Nayler. Fire retort. Oct. 20.

1897.

18,189. O. Gottmann. See Class VII.

#### H.—FUEL, GAS, AND LIGHT.

##### APPLICATIONS.

21,508. R. P. Pictet. See Class VII.

21,602. P. Cannell-Bann. Improved mantles for gas and other burners. Sept. 21.

21,608. H. Walker. See Class VII.

21,665. F. L. Ball. Improvements in apparatus in connection with the manufacture of gases and other purposes. Sept. 22.

21,681. J. McConechy. Improvements in apparatus for the production of acetylene gas. Sept. 22.

21,747. L. Dafrance. Improvements in the manufacture of fuel. Sept. 22.

21,799. H. Maxim. Improvements in methods and apparatus for manufacturing and utilising gas, utilising waste coal, and ventilating coal mines. Sept. 23.

21,831. H. H. Lake.—From Wizard Manufacturing Company, United States. Improvements relating to the production of acetylene gas, and to lamps for generating and burning the same. Complete Specification. Sept. 23.

21,833. E. S. D. Scott and T. Hawkins. Improvements in and relating to the generation of gas for motive power, illuminating, heating, and other purposes. Sept. 23.

21,897. R. Douglas. A new or improved acetylene gas generator, more particularly intended for use in connection with lamps for velocipedes and the like. Sept. 24.

22,120. G. Hilgenstock. Improvements in coke ovens. Complete Specification. Sept. 27.

22,327. A. F. B. Gomes. Improvements in or relating to mantles for use in incandescent gas lighting. Sept. 29.

22,518. G. R. Hislop. Improvements in gas producers. Oct. 1.

22,601. W. Knowles. Artificial coal. Oct. 2.

22,625. W. L. Voelker. Processes for manufacturing incandescent materials. Complete Specification. Oct. 2.

22,626. W. L. Voelker. Improvements in incandescent materials and mantles and the process of making the same. Complete Specification. Oct. 2.

22,648. J. A. Ageron and L. P. Wirth. Improvements in and connected with apparatus for the generation and combustion of acetylene gas. Oct. 2.

22,730. A. Flock. Improved apparatus for producing acetylene gas. Complete Specification. Oct. 4.

22,755. E. A. Prost. Improvements in or relating to apparatus for the production of acetylene gas. Oct. 4.

22,850. W. H. Wheatley.—From C. W. Beck, United States. Improvements in lamps for generating and burning acetylene gas. Oct. 5.

22,918. C. J. Bailey and J. H. Nicklin. Improved apparatus for the generation of acetylene gas. Oct. 6.

22,929. J. Whitehead and A. Slater. Improvements in automatic apparatus for the generation and storage of acetylene gas. Oct. 6.

23,198. E. Bosshardt.—From A. Moler, Argentine Republic. An automatic apparatus entitled "spirit" for the production of acetylene gas. Complete Specification. Oct. 9.

23,237. O. Imray.—From E. Pilous and A. M. Michachis, Austria. Process for enriching gas of low illuminating power. Oct. 9.

23,273. W. Ackroyd. Improvements in apparatus for generating, delivering, and storing acetylene gas. Oct. 11.

23,287. E. Sriwan. Improvements in and connected with mantles for incandescent lights. Oct. 11.

23,351. O. V. Sigurdsson. Improvements in apparatus employed in the manufacture of acetylene gas. Oct. 11.

23,411. J. Riley and W. Lawson. Improvements in oxygen generators. Oct. 12.

23,450. J. E. Speller. Improvements in apparatus for generating acetylene gas. Oct. 12.

23,458. M. Wagner and A. Pfemmett. Improvements in apparatus for the production of acetylene gas. Oct. 12.

23,543. T. Edmondson and F. Entwisle. Improvements in apparatus for the generation of acetylene gas. Oct. 13.

\* See Note (\*) on previous page.

- 23,545. W. Schenk. Improvements in the manufacture of mantles for incandescent lights. Oct. 13.  
 23,547. A. Wartenweiler and R. Spengler. Improvements in automatic apparatus for the production of acetylene gas. Oct. 13.  
 23,793. C. J. Lundström. Improvements in the preservation of carbide and its subsequent treatment for use in the production of gas. Complete Specification. Oct. 15.  
 23,802. L. S. Burlington. Improvements in acetylene gas generators. Complete Specification. Oct. 15.  
 23,887. B. J. Attebury. See Class XVII.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 19,677. P. R. de F. d'Hamy. Manufacture of fuel briquettes. Oct. 17.  
 25,221. I. X. V. Bablon. Production of acetylene gas and apparatus therefor. Oct. 13.  
 25,762. M. Arndt. Gas-absorbing apparatus for ascertaining the quantity of a particular gas in a gaseous mixture. Sept. 29.  
 26,041. C. C. Connor. Electrodes. Sept. 29.  
 26,618. J. F. Duke. Manufacture of mantles or incandescent bodies for incandescent gas lamps. Sept. 29.  
 26,897. J. Vaughan-Sherin. Apparatus for the production and utilisation of acetylene gas. Oct. 6.  
 27,574. E. Gossart and H. Chevalier. Means for regulating the production of acetylene gas, and lamps therefor. Oct. 20.  
 28,279. Sir C. S. Forbes, Bart. Apparatus for automatically regulating the supply of liquid fuel. Oct. 13.  
 28,290. F. V. C. Brokk. Vaporiser for liquid combustibles for incandescent lighting or heating purposes. Oct. 13.  
 28,853. W. P. Thompson.—From The Continental-Gas Glühlicht-Actien-Gesellschaft "Meteor" vormals Kroll Berger and Co. Oil burners applicable for incandescent lighting. Oct. 20.  
 29,188. W. P. Thompson.—From L. L. H. Gerard. Apparatus for producing acetylene gas. Oct. 6.  
 29,320. P. de Plesener and H. Luchaire. Apparatus for the manufacture of acetylene. Oct. 6.  
 29,556. J. O. O'Brien.—From P. P. H. Mace. Feed governors for apparatus for producing acetylene. Oct. 6.  
 30,037. P. de Plesener. Apparatus for manufacturing acetylene. Sept. 29.

1897.

262. W. M. Ward. See Class XVIII.  
 9762. J. G. A. Kitchen. Burners for acetylene. Sept. 29.  
 15,261. F. Alomann. Apparatus for generating a vaporous or gaseous mixture from hydrocarbon containing liquid and water for the production of a blue flame. Oct. 6.  
 15,369. E. F. J. C. Bauweraerts. Carbonetting of illuminating gas and apparatus therefor. Oct. 6.  
 17,927. M. Bernstein. Petroleum blue flame burners for incandescent lighting and heating purposes. Oct. 6.  
 17,938. A. Rieffel. Apparatus for the production of acetylene gas. Oct. 20.  
 19,149. W. E. Koehs. Coke ovens and machinery in connection therewith. Oct. 13.  
 19,823. T. Thorp and T. G. Marsh. Apparatus for the production of acetylene from calcium carbide and water. Oct. 6.  
 20,052. F. Rhind. Gas generating lamps. Oct. 13.  
 20,225. L. Freudenthal. Improved solution or fluid for impregnating incandescent bodies. Oct. 6.  
 20,571. O. Kahns. Process and apparatus for the production of carburetted air for incandescent gas light. Oct. 13.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

## APPLICATION.

- 22,716. A. Adiasewich. Treatment of petroleum or bitumen for production of pitch, aromatic hydrocarbons, and antiseptics therefrom, and apparatus for that purpose. Oct. 4.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 23,771. G. Schultz. Obtaining benzol and similar aromatic hydrocarbons. Sept. 29.  
 27,527. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Manufacture of preparations of guaiacol, creosote, and other higher phenols. Oct. 20.

1897.

5698. A. Basch and H. Graepel. Carbonising, charring, or coking combustible substances. Sept. 29.

## IV.—COLOURING MATTERS AND DYES.

## APPLICATIONS.

- 21,553. A. G. Green and A. R. Wahl. Improvements in the production of colouring-matters for cotton. Sept. 20.  
 21,825. A. G. Green, A. R. Wahl, and The Clayton Aniline Company, Ltd. The manufacture or production of paranitrobenzaldehyde ortho-sulphonic acid and colouring matters therefrom. Sept. 23.  
 21,968. I. Levinstein and Levinstein, Ltd. Manufacture or production of aromatic aldehydes and of colouring matters therefrom. Sept. 25.  
 21,991. J. Möller. Ink. Complete Specification. Sept. 25.  
 22,121. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier, France. Improvements in the production of aromatic aldehydes. Sept. 27.  
 22,242. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of blue basic safranine azo-dyes. Sept. 28.  
 22,677. A. Ashworth and J. Bürger. Improvements in the production of colouring matters. Complete Specification. Oct. 4.  
 23,017. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of chemical compounds of the aromatic series. Oct. 7.  
 23,248. A. G. Green and A. R. Wahl. Improvements in the manufacture and production of colouring matters. Oct. 9.  
 23,370. C. D. Abel.—From Chemische Fabrik Rheuania, Germany. Manufacture of para-acetamidophenoxy-acetamide mono- and di-alkylparaacetamidophenoxyacetamides and chloral derivatives. Oct. 11.  
 23,816. A. Ashworth and J. Bürger. Improvements in the production of colouring matters. Complete Specification. Oct. 16.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 21,638. L. P. Marchlewski, E. S. Wilson, and E. Stewart. Production of dyes. Sept. 29.  
 25,592. C. W. Anderson, H. Benjamin, and J. Mendess. Liquid compound for dyeing purposes, also applicable for detergent, purifying, and disinfecting purposes. Oct. 13.  
 26,020. Read Helliody and Sons, Ltd., J. Turner, and H. Dean. Production of sulpho acids and colouring matters therefrom. Oct. 20.  
 26,139. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Production of chemical compounds of the aromatic series. Sept. 29.  
 26,210. W. H. Claus, A. Ree, and L. Marchlewski. Production of new azo-colouring matters. Oct. 6.  
 26,666. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Schering. Manufacture of isomeric, unsymmetrical acetonealkamines, and acidyl derivatives therefrom. Oct. 20.  
 27,896. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of basic dis-azo dyestuffs. Oct. 13.  
 28,499. A. G. Green. Production of paranitraniline red. Oct. 13.  
 29,717. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Manufacture of chlorine derivatives of toluene. Oct. 20.

1897.

6581. W. Majert. Method of producing and purifying orthotoluol-sulpho-chloride. Oct. 6.

18,762. A. Ashworth. Manufacture of colouring matters suitable for dyeing unmodified cotton. Sept. 29.

#### V.—TEXTILES, COTTON, WOOL, SILK, ETC.

##### APPLICATIONS.

21,632. G. C. Dymond.—From Storm and Brackenbergh, Hollaud. Improved process and composition for rendering cloth, cellulose, paper, and the like, fireproof. Sept. 21.

21,719. M. Rivizza and R. Schönlin.—From J. R. Bantz, Germany. An improved process for impregnating woollen fabrics intended for keeping the human body at an equal temperature. Sept. 22.

21,801. W. G. Thomson. Improvements in the method of and apparatus for manufacturing inlaid linoleum and other floorcloths. Sept. 23.

21,983. J. Newell. Improvements in the method of and apparatus for singeing, gassing, or genapping yarn. Sept. 25.

22,351. E. Remy. Improvements relating to the washing and like treatment of printed fabrics, and to apparatus therefor. Sept. 29.

22,477. F. Holschmidt. Improvements in and relating to the manufacture of fabrics. Complete Specification. Sept. 30.

23,670. W. P. Ingham. Improvements in or connected with the manufacture of slag wool. Oct. 14.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,557. R. B. Hardman. Apparatus for cleaning fibres from grease and impurities. Sept. 29.

22,197. W. C. Kipling. Waterproofing silk, wool, or other fabrics. Oct. 6.

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

##### APPLICATIONS.

22,295. J. Heartwell. Improvements in and connected with bleaching and similar kiers. Sept. 29.

22,459. E. Cabati. An improved process of bleaching fabrics. Sept. 30.

22,551. W. Lowe. Improvements in printing textile fabrics with basic dyes or aniline black ground. Oct. 1.

22,786. P. Reid and H. Thorp. Improvements in dyeing textile fibres, yarns, and fabrics. Oct. 5.

23,483. T. Trusher. Improvements in apparatus for treating fibrous materials with dye or other liquors. Oct. 12.

23,484. T. Trusher. Improvements in apparatus for treating fibrous materials with dye or other liquors. Oct. 12.

23,485. T. Trusher. Improvements in apparatus for treating fibrous materials with dye or other liquors. Oct. 12.

23,644. A. J. Craig. Improvements in apparatus for scouring, dyeing, and washing woollen, cotton, or other textile materials and fabrics. Oct. 14.

23,688. J. Brandwood. A new or improved machine or apparatus for boiling, bleaching, mordanting, dyeing, or drying vegetable or animal fibres in the raw state, in the hank or in the cop, or on the bobbin or cheese, or other compact forms. Oct. 14.

23,689. J. Brandwood, J. Taylor, and W. Ogden. A new or improved apparatus or appliance for dyeing cops on cop-dyeing machines without spindles or skewers. Oct. 14.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

27,742. H. W. Kearns and J. Barnes. Production of fast colours upon vegetable fibre. Oct. 13.

28,266. A. F. B. Gomess. Bleaching textile vegetable fibres, yarns, and fabrics. Oct. 20.

#### VII.—ACIDS, ALKALIS, AND SALTS.

##### APPLICATIONS.

21,508. R. P. Pictet. Improvements in the process and apparatus for the production of carbide of calcium. Date applied for Feb. 20, 1897, being date of application in France. Sept. 20.

21,608. H. Walker. Improvements in the method of and apparatus for the manufacture of calcium carbide. Sept. 21.

21,940. The Aluminium Company, Ltd., and A. G. Haddock. Improvements in bleaching compounds. Sept. 21.

22,136. F. Lutz. An improved process for the preparation of carbolic acid. Sept. 27.

22,395. W. Garroway. Improvements in the manufacture of lead carbonate, ammonium nitrate, silicates of sodium, and caustic soda. Sept. 30.

22,790. I. Levinstein and Levinstein, Ltd. Improvements in and connected with the concentration of sulphuric acid, and with apparatus therefor. Oct. 5.

23,053. H. Higgins. Improvements in or relating to the evaporation of saline and like solutions, and the desiccation of the product thereof. Oct. 7.

23,163. C. P. F. Despréz and E. A. Duthuit. Improvements in the manufacture of blocks of calcium carbide. Date applied for March 8, 1897, being date of application in France. Oct. 8.

23,195. T. H. Cobley. Improvements in the production of colloidal tannates for use in land and marine steam boilers. Oct. 9.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

22,717. G. Kynoch and Co., Ltd., and A. T. Cocking. Method and apparatus for mixing and conveying acids for use in nitroglycerin and other manufactures. Sept. 29.

27,769. E. Dyson. Apparatus for concentrating sulphuric and other acids. Oct. 6.

29,922. J. D. Gilmour. Drying alkaline cyanides. Oct. 6.

1897.

17,834. E. F. Turner. Treatment of metallic chlorides, such as those produced from sulphide ores. Sept. 29.

18,189. O. Guttmann. Apparatus for converting nitric peroxide into nitric acid. Sept. 29.

#### VIII.—GLASS, POTTERY, AND ENAMELS.

##### APPLICATIONS.

22,033. T. Krah. Improved apparatus for pressing and moulding glass and the like. Complete Specification. Sept. 25.

23,080. W. S. Hadley, F. W. Sephton, and R. Mills. Improvements in the method of and means for producing indelible designs upon the surface of glass, marble, metal, and similar material. Oct. 8.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

25,665. J. Duckett and Son, Ltd., J. Duckett, and J. W. Bullock. Construction of muffled and semi-muffled kilns for burning biscuit and glazed ware. Oct. 13.

1897.

19,003. H. Brooke and J. C. Grout. Apparatus for the manufacture of glass. Oct. 6.

19,493. C. C. Hartung. Making plate glass. Oct. 6.

20,388. J. B. Vernay. Automatic machine for the manufacture of bottles and other articles of glass. Oct. 6.

#### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

##### APPLICATIONS.

21,921. C. W. Luther. A new way of constructing light fireproof building material possessed of the quality not to be eaten by insects, and therefore specially adapted for hot climates. Complete Specification. Sept. 24.

22,254. E. M. Fox. An improved compound or solution for the treatment of wood or other substances to render them unflammable. Sept. 28.

22,271. K. Kunze. Improvements in the manufacture of artificial stone. Sept. 28.

23,515. W. Smith. Improvements in the manufacture of plaster. Oct. 13.

##### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

14,673. F. D. T. Lehmann and P. N. Kohlsaat. Kilns for burning bricks, tiles, lime, and the like. Oct. 6.

21,781. A. C. Ponton. Manufacture of fire-bricks and fireproof mortar. Oct. 6.

24,711. R. Hunter. Manufacture of finely pulverised substances for use in the production of Portland cement, pigments, and the like. Sept. 29.

27,618. A. Taylor. Manufacture of artificial stone for building, paving, and other suitable purposes. Oct. 6.

1897.

1795. La Société Metallurgique de Champiguelles et Neuves-Maisons. Manufacture of an improved cement. Oct. 20.

## X.—METALLURGY, MINING, ETC.

### APPLICATIONS.

21,552. E. C. F. Otto. A new or improved process for case-hardening iron or mild steel partially applicable to hardening steel. Sept. 20.

21,736. R. W. E. MacIvor. Improvements in the treatment of gold ores and slimes and apparatus therefor. Sept. 22.

21,963. W. J. H. Jones and C. H. Moon. Improvements in the annealing of metals drawn into wire. Sept. 25.

21,984. G. Thomson. Improvements in alloys or metallic compounds containing steel. Sept. 25.

22,256. The General Gold Extracting Company, Ltd.—From L. Peletan, France. Improvements in and in apparatus for the treatment of ores or the like containing gold or silver, or both gold and silver for the obtaining of the precious metal therefrom. Sept. 28.

22,666. C. Jones. Improvements in the construction of furnaces for heating baths or pots of metal for tin plating lead coating, galvanising, or the like. Oct. 4.

22,815. R. Clarke and C. Flower. A new and improved white metal or alloy and the process of producing the same. Oct. 5.

22,938. H. Maxim. An improved method of and apparatus for applying intense heat to the surfaces of metallic and other bodies, and also for the complete fusion of bodies. Oct. 6.

22,961. G. Weil and A. Lévy. Improved processes for coating aluminium or other metals with silver or other metals. Oct. 6.

23,177. W. Allen and A. H. Plante. A solder for uniting aluminium. Oct. 9.

23,267. J. E. Bryant. Improvements in apparatus for the electro-deposition of one metal on another. Oct. 11.

23,278. J. Bedford and J. Ashton. Improvements in the production of compound steel bars for making cutting tools and the like. Oct. 11.

23,335. F. J. Rutter. Improved means applicable for use in obtaining metals from sulphide ores. Oct. 11.

23,883. R. B. Thomas and H. S. Thomas. Improvements in the treatment of iron or steel plates or sheets to be afterwards coated with tin or terne metal or other coating metal or alloy or to be otherwise coated or used uncoated and in apparatus employed in the said treatment. Oct. 16.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,976. A. L. Le Redotte. Manufacture of certain metals and alloys, especially magnesium and its alloys. Oct. 13.

22,791. T. Teague. Bar tin or metal casting machine. Oct. 6.

24,705. R. A. Hadfield. Manufacture or production of metallic alloys. Oct. 6.

25,462. W. P. Thompson.—From La Société Civile d'Etudes du Syndicat de l'Acier Gerard. Pulverisation of metals with a view to the manufacture of steel and for other purposes. Oct. 6.

25,611. H. Maxim. Method and apparatus for manufacturing calcium carbide and for the reduction of metals from their oxides. Oct. 20.

27,727. P. E. Placet. Purification of aluminium and apparatus therefor. Oct. 13.

29,846. S. Danner. Manufacture of crucible steel. Oct. 6.

1897.

6991. H. Griffith, jun.—From V. Coppee and A. E. Kempen. Improvements relating to aluminium. Oct. 20.

6993. H. Griffith, jun.—From V. Coppee and A. E. Kempen. The brazing of aluminium. Oct. 20.

14,325. C. C. E. Bohne. Treatment of slag resulting from the smelting of tin ore. Sept. 29.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### APPLICATIONS.

21,637. W. Decker and G. von Struve. Improvements in and relating to electrolytes for secondary batteries. Complete Specification. Sept. 21.

21,704. S. W. Hart. Improvements in secondary electric batteries or accumulators. Sept. 22.

21,705. S. W. Hart. Improvements in and relating to secondary electric batteries or accumulators. Sept. 22.

21,819. E. J. Wade. Improvements in and connected with electrical storage batteries. Sept. 23.

21,976. F. Greenfield. Improvements in appliances used in connection with the electro-deposition of metals. Sept. 25.

22,044. R. W. James.—From The Bell Electric Company, United States. Improvements in electric batteries, electrodes, and method of making the same. Complete Specification. Sept. 25.

22,045. R. W. James.—From The Bell Electric Company, United States. Improvements in electric batteries. Complete Specification. Sept. 25.

22,203. A. J. Boulton.—From F. H. Soden, United States. Process of and apparatus for electrically treating ore. Complete Specification. Sept. 28.

22,549. G. F. W. Morris.—From S. Bash, Argentine Republic. Improvements in single liquid voltaic batteries. Oct. 1.

23,329. G. Platner. Improvements in and connected with substances to prevent polarisation in electric batteries. Complete Specification. Oct. 11.

23,332. E. A. Paris. Improvements in secondary battery plates or electrodes. Oct. 11.

23,352. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Schering, Germany. Improvements in the manufacture of electrodes for electrolytic purposes. Oct. 11.

23,489. C. P. Eliason. Improvements in electric storage cells. Oct. 12.

23,602. E. J. J. B. Benoit. Improvements in anodes of electro-decomposing apparatus. Oct. 13.

### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

21,273. J. E. Liardet. Electric storage batteries. Sept. 29.

28,139. A. Dodd. Lead accumulators. Oct. 20.

1897.

996. W. Majert. Accumulator plates. Sept. 29.

18,628. C. H. Cole. Portable electric primary batteries. Sept. 29.

19,035. H. S. Jones, of the firm of W. P. Thompson and Co.—From E. Balbach, jun., United States. Electrolytic apparatus. Oct. 20.

## XII.—FATS, OILS, AND SOAP.

### APPLICATIONS.

21,749. J. C. W. Stanley and T. B. C. Hardman. Improvements in or relating to the extraction of oil from cocoa and other nuts. Sept. 22.

21,832. F. S. D. Scott and T. Hawkins. An improved soap for toilet and other purposes. Sept. 23.

22,123. J. G. Haller. Improvements in the manufacture of glycerine from spent soap leys. Sept. 27.

22,140. E. T. F. Goodwin. Improvements in toilet and other soaps. Sept. 27.

22,810. R. Holliday and Sons, Ltd., and T. Holliday. Improvements in the manufacture of soap. Oct. 5.

22,862. F. Arledter. Improvements in the manufacture of resinous soap. Oct. 5.

23,140. T. Arthur. A solution for washing and cleansing glass and painted and varnished surfaces. Complete Specification. Oct. 8.

23,197. J. Monterrabio. An improved system for manufacturing soaps by the direct employment of oleaginous seeds. Complete Specification. Oct. 9.

23,612. H. J. Gardiner. An improved detergent compound for woollen goods and the like. Oct. 13.

23,700. J. Mendess. Improvements in compounds for cleansing and dyeing purposes. Oct. 14.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

26,007. W. R. Harrison and E. Stephenson. Apparatus for brightening and clarifying crude oils. Oct. 13.

1897.

19,429. F. Arledter. Manufacture of resinous soap, and apparatus therefor. Oct. 13.

#### XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

##### APPLICATIONS.

21,718. R. Strobenitz and J. Fried. Process for manufacturing black pigments from carbonaceous materials. Complete Specification. Sept. 22.

22,514. W. Ellis. The combination of india-rubber with other chemical substances, which impart to the product a quality useful in certain manufactures. Oct. 1.

22,792. L. Hunt. A new or improved non-poisonous and permanent white paint or varnish. Oct. 5.

22,808. H. Cotton. A lacquer to be applied for the prevention of atmospheric oxidation of gold leaf, silver leaf, Dutch metal leaves, and the like, as used by decorators for interior decorations. Oct. 5.

22,867. H. L. Bates. An improved paint. Complete Specification. Oct. 5.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

23,294. The Non-Corrosive Preserving and Fire-Resisting Paint Co., Ltd., F. White, and J. Thomson. Non-corrosive preserving and fire-resisting paint. Oct. 20.

24,711. R. Hunter. See Class IX. Sept. 29.

25,779. H. Helbing and G. Pertsch. Preparation and application of coating and insulating materials for medical and other purposes. Oct. 13.

26,322. J. Fairlie. Manufacture of red lead. Oct. 6.

26,695. F. H. Smith and C. Macintosh and Co., Ltd. Manufacture of rubber compounds. Oct. 13.

1897.

16,490. J. Stocker and H. Zander. Improved weather acid and fire-resistant material. Oct. 6.

19,030. A. H. Eyles. Apparatus for use in the manufacture of white lead. Oct. 6.

19,736. J. E. Bedford and C. S. Bedford. Manufacture of varnish. Oct. 13.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

##### APPLICATIONS.

21,601. E. H. Dewson. Improvements in the tanning of hides and skins and the like, for the production of leather and in the apparatus employed therein. Complete Specification. Sept. 21.

22,361. G. Levinstein. Improvements in and relating to the tanning of hides and skins. Sept. 29.

23,194. T. H. Cobley. Improvements in the manufacture of tannin preparations, concentrating and blending same for tanning and dyeing and other purposes. Oct. 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1897.

13,997. W. Turner. Apparatus for working or treating skins, hides, or leather. Oct. 20.

18,332. E. J. Thibaut. Means to be used in tanning hides and skins. Oct. 13.

19,661. H. Bolder. Liquid casein glue. Oct. 20.

19,874. E. Du Bois. Apparatus for tanning. Oct. 6.

20,354. E. J. Thibaut. Means to be used in the tanning of hides and skins. Oct. 13.

#### XVI.—SUGARS, STARCHES, GUMS, Etc.

##### APPLICATIONS.

21,533. B. J. B. Mills.—From E. Leconte, France. Improvements in the manufacture of dextrine and applications of the same. Sept. 20.

22,532. G. S. Baker and W. K. Baker. Improvements in or relating to the manufacture of sugar, glucose, and the like, and apparatus therefor. Oct. 1.

23,875. H. Higgins. Improvements in or relating to the manufacture of lactose or sugar of milk. Oct. 16.

#### XVII.—BREWING, WINES, SPIRITS, Etc.

##### APPLICATIONS.

21,878. E. Zdzarek. Improvements in the manufacture of ethyl-alcohol. Complete Specification. Sept. 24.

22,481. E. de Menlemester. A process for treating maize and other cereals, for use in the manufacture of beer and alimentary substances, and in distilling. Sept. 30.

22,617. R. D. Bailey. Improved processes of producing brewers' and distillers' wort for fermentation. Oct. 2.

22,816. A. D. Watson. An improved process for the extraction of the Plasma (cell contents) and the separation of cellulose from yeast. Oct. 5.

23,925. B. J. Atterbury. Improvement in the production of ethyllic alcohol. Oct. 7.

23,249. J. D. Möller. An improved method of improving or oxidizing alcoholic beverages. Complete Specification. Oct. 9.

23,341. M. L. Wheatley. Improvements in or relating to the preservation of brewers' grains and other material. Oct. 11.

23,724. J. B. Hilliard. See Class I.

23,887. B. J. Atterbury. Improvements in the production of alcohols and bye products, and in apparatus therefor, and for the production of acetylene gas. Oct. 16.

#### XVIII.—FOODS, SANITATION, Etc., AND DISINFECTANTS.

##### APPLICATIONS.

##### A.—Foods.

21,995. J. A. L. F. Janasz. An improved treatment of the milk of cows or other domesticated animals to render it suitable as food for infants and children. Sept. 25.

22,112. H. A. Laeroix and A. C. de Candemberg. Process of preserving organic compounds. Sept. 27.

22,686. L. Wacker. Process and apparatus for preserving meat. Oct. 4.

22,838. J. Meeredy. Improvements in and connected with the desiccation of eggs and in apparatus therefor. Oct. 5.

22,839. J. Meeredy. Improvements in the desiccation of articles of food and in means or apparatus therefor. Oct. 5.

22,840. J. Meeredy. Improvements in and relating to the desiccation of articles of food. Oct. 5.

23,149. W. J. Engledue. Improvements in or relating to the preservation of milk and milk products. Oct. 8.

##### B.—Sanitation.

21,982. W. Watson. Improvements in the method of and apparatus for purifying and softening or similarly treating sewage and other impure water. Sept. 25.

22,128. C. R. Bilange. Improvements in the treatment and utilisation of excreta and other refuse and in apparatus therefor. Sept. 27.

22,965. D. Cameron, F. J. Commin, and A. J. Martin. See Class I.

23,107. J. Grossmann. Improved method of treating sewage. Oct. 8.

23,428. W. H. L. Galloway.—From J. E. Jordan, South African Republic. Improvements in or relating to machinery or apparatus for treating, softening, and purifying water, sewage, slimes, or other liquids or matters held in solution or suspension. Oct. 12.

23,604. A. Zimmermann.—From H. Krell, Germany. An improved process for disinfecting and in apparatus therefor. Oct. 13.

23,787. C. J. Whittaker and W. C. Bryant. Improvements in the treatment of sewage and in apparatus therefor. Oct. 15.

*C.—Disinfectants.*

22,716. A. Adiassewiche. See Class III.

COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Foods.*

1896.

14,209. R. G. Nash. Aeration and preservation of milk and apparatus therefor. Sept. 29.

24,587. J. Garton, M. E. G. Finch-Hatton, and R. Garton. Treatment of grain and the manufacture of food-stuffs therefrom. Oct. 13.

1897.

899. J. J. Hazard. Preservation of organic matters and apparatus for use in connection therewith. Sept. 29.

15,884. L. Michon and M. E. Gouliet. Preserving alimentary products. Oct. 13.

19,446. H. Grons and H. Pateson. Chilling and freezing meat and other alimentary substances and means therefor. Sept. 29.

*B.—Sanitation.*

1896.

22,768. C. Fell. Filter for sewage effluent and the like. Oct. 20.

26,667. A. Zimmermann.—From The Chemische Fabrik auf Actien vormals E. Schering. Disinfecting and apparatus therefor. Oct. 6.

29,009. J. F. G. de Bonardi (Marquis du Menil). Method and furnace for the incineration of so-called garbage and the recovery of ammonia therefrom. Oct. 20.

1897.

262. W. M. Ward. Mode, means, and apparatus for treating smoke for the extraction of the carbon and other residual products resulting from imperfect combustion. Oct. 6.

19,426. J. De-maroux. Apparatus for sterilising water. Oct. 13.

*C.—Disinfectants.*

1896.

25,592. C. W. Anderson. H. Benjamin and J. Mendess. See Class IV. Oct. 13.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

22,630. E. Sonstadt and J. M. Landon. Improvements in the treatment or manufacture of paper. Oct. 2.

22,859. C. Endruweit. An improved process for the metallic coating of paper. Complete Specification. Oct. 5.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

23,001. J. Y. Johnson.—From C. F. Boehringer and Soehne, Germany. Improvements in the manufacture or preparation of adenin. Oct. 7.

23,005. J. Y. Johnson.—From C. F. Boehringer and Soehne, Germany. Improvements in the manufacture or preparation of hidrooxanthine, paraxanthine, and methylated hypoxanthines. Oct. 7.

23,227. J. Y. Johnson.—From C. F. Boehringer and Soehne, Germany. Improvements in the production of oxypurines and their alkyl derivatives from trichloropurine. Oct. 9.

23,355. P. E. M. Jamain. Improvements in apparatus for compressing pharmaceutical and other powders for the manufacture of tablets. Date applied for Aug. 9, 1897, being date of application in France. Oct. 11.

23,584. M. Otto. Improvements in the production of iodoform. Oct. 13.

23,719. E. de Laire. Manufacture of a new product from ionone or pseudo-ionone. Oct. 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

24,799. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Production of a pharmaceutical compound. Sept. 29.

25,905. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Manufacture of a new salt of piperazine. Oct. 6.

26,350. A. J. Boulton.—From F. Fritzsche and Co. Manufacture of artificial essence or essential oil of violets. Oct. 13.

27,655. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Manufacture of benzoic sulphinate. Oct. 13.

27,656. G. B. Ellis.—From La Société Chimique des Usines du Rhône anciennement G. P. Monnet et Cartier. Production of formic aldehyde vapours. Oct. 13.

XXI.—PHOTOGRAPHY.

APPLICATIONS.

21,679. G. A. de Katow.—From A. Schwarz, Germany. Improvements in method of and apparatus for toning photographs. Complete Specification. Sept. 22.

23,739. H. W. Cottrell. An improved method of producing coloured photographs. Oct. 15.

30,161. M. Jolles and L. Lilienfeld. Improved photographic printing paper or the like. Oct. 13.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

23,340. G. Beneké. Improvements in the manufacture of explosive compounds. Oct. 11.

23,353. G. A. Witt.—From P. Cornet, Belgium. Improvements in explosives. Oct. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

22,717. G. Kynoch and Co., Ltd., and A. T. Cocking. See Class VII. Sept. 29.

26,253. Vickers, Sons, and Co., Ltd., A. F. Dawson, and G. T. Buckham. Primers for ordnance. Oct. 6.

28,889. G. Kynoch and Co., Ltd., and A. T. Cocking. Explosives. Oct. 20.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

23,321. F. Huger-shoff. Improvements in or relating to centrifugal machines for examining and testing milk, sediments of urine, and other fluid substances. Complete Specification. Oct. 11.

PATENTS UNCLASSIFIABLE.

APPLICATIONS.

23,126. A. J. Boulton.—From A. O. Richter, Germany. Improved compound for use in extinguishing fires. Complete Specification. Oct. 8.

23,229. D. G. Dow. Improvements in and relating to fire-resisting material. Oct. 9.

23,330. T. Oddy and C. Heap. Improvements in and apparatus for the manufacture of certain carbonaceous compounds. Oct. 11.

23,874. E. Heusch. Improved manufacture of artificial mother-of-pearl. Oct. 16.

COMPLETE SPECIFICATION ACCEPTED.

1897.

17,610. J. Carnick. Preparing protonuclien. Oct. 6.

# Society of Chemical Industry.

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 11.—Vol. XVI.]

NOVEMBER 30, 1897.

[Non-Members 30/- per annum; Members 25/- per Set of extra or back numbers; Single Copies (Members only) 2 6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Munspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Dr. Edward Schunck, F.R.S.	1896—1897.

## COUNCIL FOR YEAR ENDING JULY, 1898.

President: Prof. F. Clowes, D.Sc.

### Vice-Presidents:

David Howard.	Dr. W. Jay Schieffelin.
Prof. A. K. Huntington.	Dr. Edward Schunck, F.R.S.
Ivan Levinstein.	G. N. Stoker.
Boverton Redwood.	Dr. T. E. Thorpe, F.R.S.
Sir H. E. Roscoe, F.R.S.	Wm. Thorp, B.Sc.
A. Gordon Salamon.	Thomas Tyrer.

### Ordinary Members of Council:

R. Forbes Carpenter.	C. C. Hutchinson.
R. Le Neve Foster.	J. S. McArthur.
Sir David Gamble, Bart., C.B.	B. E. R. Newlands.
Oscar Guttman.	John Pattinson.
Douglas Herman.	Sir Robert Pullar.
Prof. J. J. Hummel.	Walter F. Reid.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

A. H. Allen.	C. Clarke Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	J. Lewkowsitch, Ph.D.
H. Brunner.	A. R. Ling.
A. C. Clandet.	Stevenson Macadam, Ph.D.
E. Rider Cook.	Ludwig Mond, F.R.S.
Chas. Dreyfus.	B. E. R. Newlands.
Sir John Evans, K.C.B., F.R.S.	John Pattinson.
G. G. Henderson, D.Sc.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	H. R. Procter.
D. B. Hewitt, M.D.	Boverton Redwood.
David Howard.	Walter F. Reid.
Prof. J. J. Hummel.	John Spiller.
Prof. A. K. Huntington.	William Thorp.
F. Hurter, Ph.D.	Thomas Tyrer.

## NOTICES.

### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, half of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time; and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30); Libraries, Corporations, and Exchanges on the Society's List.

To Subscribers .....	Each copy 10s.
To others.....	12s. 6d.
	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

Foreign and Colonial Members are reminded that the subscription of 25s. for 1898, payable on January 1st next, should be sent in good time to the Treasurer, in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th, 1898.

#### LIST OF MEMBERS ELECTED 23rd NOVEMBER 1897.

- Appleton, Jno. Howard, 209, Angell Street, Providence, R.I., U.S.A., Professor of Chemistry (Brown University).  
 Blair, Andrew A., 406, Locust Street, Philadelphia, Pa., U.S.A., Analytical Chemist.  
 Borland, C. Randolph, Oakland, Bergen Co., N.J., U.S.A., Chemist (American E.C. and Schultze Powder Co.).  
 Burner, Nathan L., 386, Hamilton Avenue, Columbus, Ohio, U.S.A., Chemist.  
 Burnet, Jno. Jas., 18, University Avenue, Glasgow, Architect.  
 Burwell, A. W., 34, Atwater Building, Cleveland, Ohio, U.S.A., Consulting Chemist.  
 Christie, E. J. Craig, 30, George Square, Glasgow, Merchant.  
 Cowburn, Arthur W., Fernroyd, St. Margaret's Road, Bowdon, Cheshire, Chemical Merchant and Analytical Chemist.  
 Dohme, Dr. Alfred B. L., c/o Sharp and Dohme, Baltimore, Md., U.S.A., Manufacturing Chemist.  
 Escher, Paul, c/o The Solvay Process Co., Syracuse, N.Y., U.S.A., Chemist.  
 Fielding, Frank E., California and Virginia Mining Co., Virginia City, Nevada, U.S.A., Assayer and Chemist.  
 Gilbody, A. Wm., M.Sc., Ph.D., A.I.C., Owens College, Manchester, Research Chemist.  
 Hudson, Thos., Isle of Cinder Oil and Grease Works, Leeds, Oil Manufacturer.  
 Hyde, Henry St. John, 210, East 18th Street, New York City, U.S.A.

### THE ADULTERATION OF PORTLAND CEMENT.

BY W. HARRY STANGER, M. INST. C.E., AND  
BERTRAM BLOUNT, F.I.C.

(See also this Journal, 1894, 1236--1237.)

During the last few years, two notable tendencies have been apparent in the manufacture of Portland cement. The first, which is altogether admirable, is the tendency of many manufacturers to study the principles of manufacture more closely than heretofore, and, as a consequence, to turn out a product of ever improving quality. The second, which cannot be too strongly condemned, is the tendency of certain other manufacturers to mix with Portland cement foreign substances of the most diverse nature, having as a rule only one property in common, *viz.*, a price smaller than that of Portland cement, and to sell the product as Portland cement.

It is not our business, nor is it our present intention, to discuss matters of purely trade interest, but it is nevertheless necessary to say here at once that the former tendency is much the stronger, and that the number and importance of the makers who illustrate the second are relatively small. In a word, the Portland cement trade of this country, as far as it is known by us, is an honestly conducted industry, and the largest and best-known makers wish to keep it so. It is also but just to say that some makers who practise the addition of foreign substances to Portland cement, do so openly, and with the avowed belief that they improve the cement thereby; and although we hold them to be mistaken, we may accept the sincerity of their convictions. Others there be who adulterate grossly and secretly until detected and ignominiously exposed. It would be waste of time to discuss their merits.

On the 30th November 1894, we were requested by the London Chamber of Commerce to undertake the investigation of the effect on Portland cement of the admixture with it of various foreign substances, especially of Kentish ragstone. The immediate cause which made such an investigation necessary was that in the Thames and Medway district certain makers had adopted the practice of adding ragstone to Portland cement, and maintained that the cement was improved by this addition. We undertook the investigation, and at once initiated a series of experiments, which were designed to be as exhaustive as possible. The work involved was long and laborious, but we were greatly aided in its successful prosecution by many of the makers interested, who provided us with samples prepared according to our directions, and also carried out a large number of tests supplementary to our own, adopting a uniform method of procedure so as to facilitate comparison of the results. We are also indebted to the courtesy of a maker who considered that the use of ragstone was an improvement, and who allowed us free access to his works, and explained his method of operation with the utmost frankness and candour. Everyone concerned showed himself anxious above all things to get at the facts, whether he had a prepossession in favour of the use of ragstone or entertained an objection to its employment, and by this just and scientific attitude contributed in no small degree to the ultimate elucidation of the question.

The results of our labours, which occupied more than a year, were embodied in a series of reports to a Special Committee of the Cement Trade Section of the London Chamber of Commerce. Together with other evidence collected by that body, they formed the basis of a report by the Section, and of a resolution to the following effect:—

"That Portland cement be defined as a mixture of two or more suitable materials, intimately and artificially mixed in the requisite proportions, and afterwards properly calcined and ground, to which nothing has been added during or after calcination, excepting that an addition not exceeding 2 per cent. of gypsum is permissible for the purpose of regulating the setting."

So important did it appear to the members of the Section to secure Portland cement from adulteration that they have drawn up the following declaration, which all manufacturers of Portland cement in Great Britain and Ireland are to be invited to sign:—

"We, the undersigned, hereby agree to conform to and carry out the rule of the Cement Trade Section of the London Chamber of Commerce, as set forth in a report made by the Section, and adopted at a meeting held on Monday the 10th of May 1897":—

"That if any material whatever, excepting an amount not exceeding 2 per cent. of gypsum for the purpose of regulating the setting, be added to the Portland cement clinker, during or after calcination, the article so produced shall not be sold as Portland cement, but under some other distinctive name."

"And we further agree that if at any time any of the parties to this agreement shall—by resolution of a majority of those present at a meeting of such parties duly and properly convened in accordance with the practice of the London Chamber of Commerce, such resolution having been duly and properly confirmed by a majority of those present at a subsequent meeting called at not less than 14 days' notice—be found to have failed to conform to and carry out the said rule, then in such case his or their name or names shall be struck off the list, and notice of the same made public in such manner as shall be resolved."

There is thus no doubt as to the attitude of the most considerable part of the cement trade in this country, and with this attitude we agree thoroughly. The technical and scientific reasons which justify this attitude are, we venture to think, largely drawn from the result of our own investigations. With the express permission of the London Chamber of Commerce—to which body and to its courteous Secretary, Mr. Kenrie B. Murray, we tender our fullest acknowledgments—we are now in a position to lay before the London Section of the Society of Chemical Industry some of the chief facts and deductions which have been the fruit of our investigation.

The facts about to be recorded give but a slight indication of the vast quantity of data which was accumulated in the course of this investigation. Even the series of reports to the London Chamber of Commerce, which were necessarily long and minute, represent only an excerpt of the work which had to be carried out. The results at our disposal

have been submitted to a severe process of compression in order to bring them within the limits of a paper.

#### Outline of the Investigation.

On the question arising as to the effect of an addition of ragstone to Portland cement, it would appear fairly obvious,

on chemical grounds, that the ragstone would be an inert substance, and could be regarded merely as a diluent. Kentish ragstone is a natural form of carbonate of lime mixed with silicious matter. It varies somewhat in composition, as may be seen from the above analyses, which are calculated on the samples free from moisture. But although thus varying, its composition is always such that when the stone is powdered and mixed with water, it is in no way cementitious, and shows no tendency to set.

Nevertheless it was stated, by those that had made the experiment, that this inert, silicious limestone could be added to Portland cement in considerable quantity (10—20 per cent.) with positive advantage to the cement. It was credibly asserted that a cement thus diluted was actually stronger than one in its normal unmixed state.

Rejecting both *a priori* views and the statements of other experimenters, we made our own tests. We may say here that in all cases our experiments have been made on cement and ragstone, ground together as in actual manufacture; separate grinding of the materials and subsequent admixture not only departs from the method practised by users of ragstone, but is likely to yield misleading results, because the intimacy of admixture is insufficiently great. Mixtures containing 10, 20, and 50 per cent. of ragstone were prepared in this manner, and tested at 7 and 28 days and at 6 months, neat and with sand, in tension and compression, and compared with corresponding tests made on the unmixed cement. The diagram below is typical of certain of the results obtained.

The composition of these samples is stated in the appended tables.

Many similar tests proved beyond doubt that some cements not only do not show a decrease in strength when mixed with 10 or 20 per cent. of ragstone, but are actually stronger when thus mixed. This is true whether the cement and mixtures are tested neat or with sand, in tension or in compression. Thus the upshot is in direct contradiction to what would certainly be expected by anyone endeavouring to solve the question on first principles. The result constitutes a useful example of the danger of making even what appear to be most reasonable assumptions, when it is open to one to dispense with assumptions altogether, and to substitute sound experimental data.

After close study, the reasons for this apparent anomaly were discerned. It became clear that when ragstone containing, as it commonly does, a small quantity of moisture, is mixed with cement clinker, and passed, together with that, through the stone-breaker and mill-stones or other grinding machinery, it is brought into the closest possible contact with the cement, and slakes any overlimed portions which

DIAGRAM OF TENSILE TESTS. SERIES "A."

may be present. Thus, a cement containing ragstone as it comes from the mills is more slaked than one free from ragstone. Now it is known that cement which is not perfectly sound is improved by limited slaking; it is on account of this that air-slaking or aeration is insisted on

DIAGRAM OF COMPRESSIVE TESTS. SERIES "A."

by many large users (notably by the Admiralty) in order to hydrate any uncombined lime or unstable lime compounds, and prevent their subsequent hydration and destructive expansion when the cement as a whole is gauged with water for preparing concrete or mortar. A moist rag-stone, ground with such a cement, performs this function of limited hydration, and thus subjects the cement to what is, in effect, an artificial and rapid aeration. Cements which are not perfectly sound are improved by this procedure. But when a cement is rendered perfectly sound by aeration, this improvement disappears, as is evident from the following diagrams.

TENSILE TESTS AFTER AERATION.

These figures show that in an aerated, and therefore perfectly sound, cement, the ragstone acts precisely as would be expected, *viz.*, as a mere diluent. The effect is the more striking because these very samples before aeration showed a smaller strength unmixed than when mixed with ragstone. That this alteration of properties is caused merely by the increased soundness of the cement, which is induced by aeration, is proved by the following table:—

In this case the cement used was not aerated by long storage and yet gave tests which were considerably lower for the mixtures containing ragstone than for the unmixed cement. It was not a cement made in the laboratory, and therefore of better grade than can be readily manufactured on a large scale, but was simply an ordinary commercial cement of high quality and perfect soundness.

A word must be said as to what is meant by the word "soundness," which has been used in the previous para-

graphs. A cement may appear perfectly sound to ordinary tests, and yet after setting may develop internal stresses which, though not sufficient to cause it to disintegrate or show any sign of actual failure, may diminish its strength appreciably. That this is not an uncommon condition is clear from the fact that many cements are considerably stronger after aeration than when fresh, as is evident from the following table:—

Breaking Weight in Pounds of Briquettes, 1" x 1" Section.  
Unmixed Cement and Sand (3 to 1).

	7 Days.		28 Days.	
	Fresh.	Aerated.	Fresh.	Aerated.
Series "A" .....	191½	256½	270	303½
" " "D" .....	250½	293½	276½	383½
" " "L" .....	131½	249½	190	340

Incidentally, it may be remarked, that this great increase in strength is a strong argument in favour of systematic and thorough aeration of all cement that is to be used in heavy and important work. This has long been practised by many engineers to ensure safety; but if the cement be even slightly unsound, a large increase of strength will also accrue.

Reverting to the question of the difference of strength of unmixed cement and cement mixed with ragstone, it will be

observed that although experiment has established that sound cement is not improved by the addition of ragstone, but is, on the contrary, deteriorated, yet the decrease of strength is smaller than that which corresponds with the percentage of diluent added. Thus a mixture of cement with 10 per cent. of ragstone is not necessarily 10 per cent. weaker, although the ragstone is merely a chemically inert addition. The reason for this discrepancy becomes clear on studying the structure of set cement. For the purpose of this study, briquettes made from unmixed cement and from cement mixed with 10, 20, and 50 per cent. of ragstone were chosen, and very thin sections were prepared from them in the manner usual in petrological research. These were examined under the microscope, and a large difference in structure was at once apparent.\*

The microscopic section of the unmixed cement consists of white, nearly opaque particles interspersed with dark patches fairly evenly distributed. Most of these dark patches are actual gaps, but some are merely plates of transparent crystalline substances, which, as they absorb little or no light, appear as gaps in the photograph.

UNMIXED CEMENT.

A similar section of a briquette containing 10 per cent. of ragstone has a much closer structure. Very few true gaps appear in it, the interstices visible in the unmixed cement being filled with fine particles of ragstone.

10 PER CENT. ADMIXTURE.

With 20 per cent. of ragstone a similar filling is perceptible, but there is also visible a greater proportion of large crystals, either transparent or opaque.

With 50 per cent. of ragstone the filling of interstices is still noticeable, but the cement is, as it were, swamped with

ragstone, and the section contains large inert crystalline masses which often exhibit cracks, and may be considered

20 PER CENT. ADMIXTURE.

as reducing the strength of the material. The appended photo-micrographs illustrate these differences of structure.

50 PER CENT. ADMIXTURE.

That the greater closeness of structure apparent in the microscopic sections of the mixtures has a physical existence, was proved by making actual measurements of the total cubic content of the cavities in the set cement and in the mixtures. A maximum density occurs with the 10 per cent. mixture, as is clear from the appended figures:—

*Volume of Cavities in a Briquette, stated in per Cent. of the total apparent Volume of the Briquette.*

	Series 1.	Series 2.
	Per Cent.	Per Cent.
Unmixed cement .....	4.63	2.39
10 per cent. mixture .....	3.83	1.80
20     "     " .....	6.32	3.79
50     "     " .....	10.43	6.32

It will be seen that although the large quantity of ragstone in the 50 per cent. mixture communicates to it a loose and porous structure, yet the 10 per cent. mixture perceptibly exceeds the unmixed cement in closeness of texture, this fact serving to confirm the microscopic observations.

From both microscopical examination of the structure, and from measurement of the cavities in briquettes of unmixed cement and of cement mixed with 10, 20, and 50 per cent. of ragstone, it is evident that a mixture containing 10 per cent. of ragstone has a closer structure than any of the others, even than unmixed cement. The ragstone in

\* The preparation of these photo-micrographs was kindly undertaken by Mr. Herbert Jackson, of King's College, London, to whose skill the beauty and accuracy of the original photographs are sufficient witness.

fact, during grinding, yields a quantity of fine powder which serves as a "filling" between the crystals formed when the cement sets. The absence of interstices thus caused appears to compensate in some measure for the fact that the rag-stone is inert, and thus a cement containing 10 per cent. of what is simply a diluent is not necessarily 10 per cent. lower in strength than an unmixed cement. In fact, a briquette, even of neat cement, may be regarded as a concrete in which the strength depends not only on the true adhesive and cohesive quality of the cement, but also on the exact fit of the particles of cement and those of the inert matter, such as the coarse core. Any fine inert filling material may improve the closeness of texture of such a concrete if the average size of its particles be such as to occupy fully the spaces naturally present in set cement.

The whole question concerning the addition of rag-tone may be summed up very briefly:—

1. Rag-tone is not a cementitious substance, and its addition to cement is an adulteration.

### TESTS FOR CONSTANCY OF VOLUME. SERIES "I."

### TESTS FOR CONSTANCY OF VOLUME. SERIES "II."

WET BAR SHOWN BY THE 8 LINES  
NEAREST LEFT HAND SIDE OF DIAGRAM

DRY BAR SHOWN BY THE 8 LINES  
NEAREST RIGHT HAND SIDE OF DIAGRAM.

2. Perfectly sound cement is weakened by the addition of rag-tone.

3. This weakening is not fully proportional to the percentage of ragstone added, because the latter acts as a fine filling material and fills up the interstices naturally present in set cement.

4. Cement which is not perfectly sound, may be temporarily improved by the addition of ragstone. When the cement has become sound by aeration, this improvement disappears.

Many minor points were examined and determined in the course of the main investigation, but the most important results are embodied in the conclusions given above.

#### Additions to Cement other than Ragstone.

One of these, which particularly came within our purview in the course of our investigation for the London Chamber of Commerce, is gypsum. Gypsum is used largely in Germany, and to a considerable extent in this country,

in quantities not exceeding two per cent., and usually smaller than this, in order to lengthen the setting time of the cement. Regarding cement as a chemically finished product in the state in which it comes from the kilns, needing nothing but mechanical comminution to make it saleable, the addition of any substance to the finished clinker must be considered, in strictness, an adulteration. Thus gypsum becomes under this definition an adulterant. Nevertheless it is added for a distinct and useful purpose, and in quantities smaller than 2 per cent. does not affect the cement injuriously, as far as our own experiments indicate. The average results obtained with cement containing proportions of gypsum increasing from 0.1 to 2.0 per cent. are given in the table below:—

*Breaking Weight of Briquettes, 1" x 1" Section. (28 Days.)*

	Sample I.	Sample II.
	Lb.	Lb.
Unmixed cement .....	618	800
0.1 per cent. gypsum .....	587	693
0.3 " " .....	630	750
0.5 " " .....	623	777
0.7 " " .....	590	813
1.0 " " .....	620	823
1.5 " " .....	657	820
2.0 " " .....	613	860

It will be seen that no harmful effect on the strength of the cement can be detected.

The effect of the gypsum on the constancy of volume of the cement was also determined by the measurement of test bars of unmixed cement and of cement mixed with 0.1 to 2.0 per cent. of gypsum in a Bauschinger apparatus. The results are recorded in the appended curves. On the whole, a slightly greater tendency to expansion is perceptible when the proportion of gypsum exceeds 1 per cent., but the difference is not so great as to warrant the conclusion that gypsum causes any dangerous amount of expansion.

With these facts before us it is evident that though gypsum is an alien addition to Portland cement and therefore technically an adulterant, its use can be defended on the ground that it confers specific properties on the cement, and does not affect its strength or soundness unfavourably. The difficulty arising in the question whether cement containing a small quantity of gypsum, added for the purpose of regulating the setting time, can be legitimately sold as Portland cement, has been met by the Cement Trade Section of the London Chamber of Commerce, by the adoption of the rule which has been quoted above. This rule (page 853) expressly excepts gypsum in quantities up to 2 per cent. from the category of substances which, if added to Portland cement, constitute an adulteration. It will be noted that this convention is similar to that which has been in use for some years in Germany, where it appears to have worked satisfactorily.

The last and worst adulterant with which it is our purpose to deal, is blast-furnace slag. As far as our experience goes, this most objectionable addition to Portland cement is not employed on the Thames and Medway, but in certain other districts it is used in large quantities for the preparation of a grossly sophisticated product which is fraudulently sold as Portland cement.

We must not be understood as condemning true slag cement made by mixing granulated blast-furnace slag with slaked lime and sold under its proper title. This material is a perfectly legitimate product, and has its own uses: no one can reasonably object to its utilisation if it is not covertly substituted for Portland cement. But the addition of blast-furnace slag to Portland cement is another matter altogether. The general practice of the manufacturers who seek to increase their profits by the use of slag, appears to be to add to the clinker as it goes to the crushers as much crude blast-furnace slag as they consider can be mixed with Portland cement without risk of detection by the ordinary consumer, who buys cement in quantities so small that the cost of its analysis is too great for him to pay. The quantity added may be as much as 30 or 40 per cent.; and detection is not easy, or even always possible, for an unskilled observer. Apart from the fraudulent character of

this addition, about which no doubt can well be entertained, there arises the question of its effect on the cement. And here it is necessary to make a small digression into the chemistry of the subject.

When Portland cement sets, a certain quantity of lime in the hydrated state is liberated. This lime in cement mortar, or concrete of fair closeness of structure remains distributed throughout the mass, and is there slowly converted into calcium carbonate. Now it is very possible that this lime could be utilised more effectively if it were provided with a certain quantity of silica, or an active silicate with which it could unite in manner similar to that of the lime of a puzzuolanic cement. Further, granulated blast-furnace slag will act as a puzzuolana and unite with slaked lime when the dry mixture of the two substances is gauged with water. It is therefore conceivable that granulated blast-furnace slag could be added to Portland cement in such quantity that its active silicates would unite with the lime set free in the normal setting of the cement. Whether this union would be advantageous to the strength of the cement is a matter for experiment. But whether it is or not, a cement thus dosed with granulated blast-furnace slag could not be legitimately termed Portland cement, and would have to be sold under a distinctive name. It may be mentioned incidentally that ordinary slag contains a good deal of sulphur (*e.g.*, 1 per cent.) in the form of calcium sulphide. This, slowly oxidising, would be likely to expand in the mass of the set cement and cause stresses, which could hardly fail to be injurious, and might be positively dangerous. Thus the burden of proof that the addition of granulated slag to cement is not actively harmful, rests upon the advocates for its use, and even if they prove their case they are confronted by the fact that the mixture is not and cannot be Portland cement.

But when the slag added to Portland cement is not granulated blast-furnace slag of the best composition for acting as a puzzuolana, but is the common stony material run out into trucks and allowed to cool spontaneously, instead of being rapidly chilled, the objection to the addition of slag is even stronger. In the first place this stony, slowly cooled slag is usually not of such a composition as to allow it to act as a puzzuolana. Next, even if it were, its condition—*i.e.*, annealed by slowly cooling instead of chilled by quenching—is most unfavourable to its puzzuolanic activity. Thus its tendency to unite with lime liberated by the setting of Portland cement would be likely to be small. It may be regarded for practical purposes as a diluent and makeweight. But this is not all; for much of this slag contains a notable proportion of sulphur, and the objectionable effect mentioned above, of the slow oxidation of this sulphur, holds equally in this case.

It is evident that the addition to Portland cement of blast-furnace slag, as usually practised, is not only an adulteration, but it is also an adulteration with a dangerous ingredient. Fortunately, this form of fraud is readily detected by analysis, although often escaping recognition by the usual mechanical tests.

In conclusion, we may reiterate our views as clearly and briefly as possible.

All materials added to Portland cement after the clinker comes from the kilns are adulterants, with the exception of gypsum, which is a recognised addition for a specific purpose in quantities not exceeding 2 per cent. Of the two adulterants which have been specially dealt with, *viz.*, rag-stone and blast-furnace slag, the latter is by far the more objectionable, and it should be condemned and rejected by makers and users alike. In this view we believe we are supported by the great majority of engineers and manufacturers.

#### DISCUSSION.

Mr. H. K. BAMBER wrote as follows:—

Kentish rag-stone could only be an adulterant in a good cement, but in a poor cement it might prevent the bad qualities having their full effect. But why make bad cement so as to require such addition? It was suggested that rag-stone acted beneficially in some cements on account of the water in it, which had the same effect as aeration. Granted the presence of water in the rag-stone, would this be taken up by the free lime only, or by some of the cement as well?

In several cases of good cements met with in the ordinary course of business, he found the gain by aeration in three days to be as nearly as possible  $\frac{1}{32}$ nd of the weight of the cement, except in a very dry atmosphere; and if exposure continued for a fortnight, no further increase of weight took place. While this increase of weight was taking place, the cement became a little lumpy, but nothing more than was easily removed by trowel or knife. The paper stated, "These figures show that in an aerated, and therefore perfectly sound cement," &c. Did that mean that an unsound and therefore bad cement became sound by mere aeration?

The results of breaking strains of cement and sand (pp. 854 and 855) were very high, and he would ask the authors if these were the results ordinary cements submitted to them in business gave, or was not this cement supplied for a special purpose by the manufacturer? Also what was its fineness? for the strength would depend on whether it contained all well-clinkered cement which had been finely ground. The authors were evidently struck with these results, for they made a kind of apology for them as follows:—"It was not a cement made in the laboratory, and therefore of better grade than can be readily manufactured on a large scale, but was simply an ordinary commercial cement of high quality and perfect soundness."

He found that aeration had but little effect, if any, on the strength of a genuine sound cement when mixed with sand. For a cement which, as before stated, gained  $\frac{1}{32}$ nd of its weight by aeration, the tensile strains averaged as follows:—

	7 Days. 14 Days. 28 Days.			Cement.	Sand.
	Lb.	Lb.	Lb.		
Without aeration ....	116	157	191	1	3
After aeration .....	133	168	192		

It was chiefly in a bad overlined cement that the beneficial effect of aeration would be shown. There was no doubt that a cement having plenty of finely ground material to fill up the interstices of the briquettes was stronger than one where the air in the briquettes was not displaced by such material; but, that being so, why not grind the cement so finely that there might be plenty of very finely ground cement to do this work instead of using an extraneous inert substance? The results would be vastly increased tensile strength in sand and cement tests. Cements were much more finely ground now, with results that could not be formerly obtained even with genuine sound cements. Even genuine ground clinker above a certain size—say the residue left on 150 sieve (22,500 meshes per sq. inch)—would not set by itself when mixed with water. The presence of blast-furnace slag with cement could have none but a most injurious effect, and would often show bluish discoloration in the briquettes made from it, owing to sulphides. Gypsum could not be called an adulterant pure and simple, for it was added to give a special property to the cement, so much desired by engineers—"slow setting," which a genuine sound new cement could not possibly have. He was experimenting on this subject at present; and although an addition of 2 per cent. of gypsum to a quick-setting cement postponed the setting from 20 minutes to six hours and more, it had beneficial results as to strength as follows:—

	7 Days' Average.	14 Days' Average.	28 Days' Average.
	Lb.	Lb.	Lb.
Cement and sand, without gypsum.	156	162	189
Cement and sand, with 2 per cent. of gypsum.	176	186	230

These experiments repeated on the same cement—

Cement and sand, without gypsum .....	116
" " " " with 2 per cent. of gypsum .....	227

In the latter case the other briquettes would be broken at two, three, and six months, to see if, in the long run, the gypsum had an injurious effect. That adding 2 per cent. of gypsum prolonged the time of setting from 20 minutes to six hours was a large result: How did it effect this? Evidently

by in some way preventing the union of the cement with water, and delay of crystallisation. This was a good effect; but, as generally with every good there was an attendant evil, would this in time have an evil effect on the cement? This retarding of the setting was lost after a time—say a month or two. Probably the gypsum, by its water of crystallisation being gradually removed by the stronger affinity of cement for water, became anhydrous, and less soluble in the water with which the cement was gauged.

Mr. W. MATTHEWS, as an engineer, felt greatly indebted to the authors for the information they had given in so clear and concise a manner. Generally speaking, he fully agreed with their views, but on one or two points he would have liked their experiments carried further. The utmost time covered with the ragstone experiments was only six months, whilst in the case of the gypsum tests it was only three months. Twenty years ago he made a series of experiments extending over eighteen months, and these showed that with good cement the increase of strength was continuous up to 12 months, or even more. He thought that if the experiments with gypsum had been continued for a longer period, they would have thrown an important light on the subject. The aeration of cement had proved so beneficial and important that it was his firm's intention in fresh contracts to provide for it being carried even further than hitherto. Some experiments made at Dover showed that the increase of bulk due to aeration resulting from six turnings was as much as 6 per cent. Taking the cost of cement at 26s. per ton, that increase of bulk was worth 1s. 6d., which would be equal to 3d. per turn, or rather more than the actual cost of turning the cement.

Mr. LEEDHAM WHITE considered that ragstone owed its effects to its hygroscopic action; and he felt convinced as a cement manufacturer having some little knowledge of chemistry, that much more was due to its mechanical qualities than to its chemical qualities. He quite agreed with the authors that the improvement in certain cements by the addition of ragstone was simply due to the filling up of the interstices. He also agreed with Mr. Bamber that this effect might be arrived at with much greater advantage by grinding the cement itself finer, and if that course were followed, better results would be obtained from the usual admixtures with sand. As regards the report itself he would like to say a few words on the conclusions arrived at. As practical men of business the committee felt that the time had come when engineers should be reassured as to the quality of the cement supplied to them, and therefore, without any wish to harass trade, they felt bound to follow in this matter the example set by Germany 20 years ago, and reduce the manufacture of Portland cement to a matter of rule and definition. No doubt there might be good admixtures of cement with other bodies, and it was conceivable that chemical science might yet discover better methods of manufacture; at the same time the committee felt that they would not be hindering the march of science if they simply defined Portland cement as "a mixture of two or more suitable materials, intimately and artificially mixed in the requisite proportions, and afterwards properly calcined and ground, to which nothing has been added during or after calcination excepting that an addition not exceeding 2 per cent. of gypsum is permissible for the purpose of regulating the setting." That would not preclude any gentleman who discovered a better article or an admixture of articles suitable for the same purpose from selling it under its proper name and description, but not as Portland cement. With regard to the gypsum, the committee, after careful consideration, had concluded that it was best dealt with in the way mentioned in the paper, since the reasons for using it were so well known. There was a difference of opinion among chemists and engineers as to its advantages or disadvantages; and the committee preferred to abide by the opinion of such authorities as the authors of this paper, knowing at the same time that they were simply going over the same ground and arriving at the same conclusions as had been adopted in Germany some 20 years ago. Any engineers who objected to the use of gypsum had the remedy in their own hands, since they had nothing to do but specify that it should not

be added to the proper components in the cement contracted for. Again, some engineers attached great value to a slow-setting cement produced in the natural way. They would probably be surprised to learn that recent experiments made by Mr. Stiles showed that this was simply due to the fact that an excess of gypsum was present initially in the chalk used in the manufacture of that cement. He was sure that it was the earnest desire of the vast body of manufacturers to work heartily and honestly with the engineers and give them the best article obtainable, and in the production of it they would be guided by technical science and by the knowledge that as cement was important to engineers, engineers were equally important to cement manufacturers.

Mr. OTTO HEHNER thought that the course which the London Chamber of Commerce had adopted in respect to the addition of gypsum to cement was liable to lead to friction and dispute. While it was easy to determine accurately the total amount of sulphuric acid contained in cement, and to calculate from this the corresponding amount of calcium sulphate, he knew of no analytical method whereby gypsum which had been intentionally added to cement could be quantitatively distinguished from the sulphates naturally present in fluctuating amounts. Thus a sample might contain naturally somewhat over 1 per cent. of sulphuric acid ( $\text{SO}_3$ ), corresponding to almost 2 per cent. of gypsum. Another might be almost free from sulphates, and would therefore stand the addition of 2 per cent. of gypsum. It would, in his opinion, have been better if the Chamber had laid down a maximum permissible limit of total sulphuric acid, than to draw a distinction between natural and added sulphates which eventually could not be enforced.

Mr. JOHN HUGHES agreed with Mr. Hehner's remarks, and said that his view was borne out by some analyses of very old mortars which he had made. For instance, the mortar from Tintern Abbey, which was of very superior quality, contained as much as 1.37 per cent. of sulphuric acid, equal to 2.33 per cent. of gypsum, and he therefore thought it was unwise to arbitrarily fix the limit of gypsum in the cement at 2 per cent. He also regretted that the authors' results had not been accompanied with chemical analyses of the cements tested, and also with grinding tests of the fineness of the ragstone and the cement respectively. Mechanical tests occupied a long time, but it was very easy to test the fineness of grinding by means of sieves, and the general quality of the cement by analysis. He thought the addition of such further results would greatly enhance the value of the paper.

Mr. A. G. BLOXAM thought it extraordinary that so small a proportion of gypsum should have so much effect on the setting of cement as had been stated. Referring to Mr. Hughes' remarks as to the large percentage of sulphuric acid found by him in ancient mortars, it was possible that that might be explained by the fact that the mortars had been exposed for centuries to a sulphurous atmosphere. On the other hand, in the case of cements, it was not improbable that much of the sulphuric acid added would be expelled by the silica during the process of burning, notwithstanding the generally basic character of cement. He would suggest that the sulphate found might be little more than that arising from the sulphur of the fuel used in kilning the cement.

Mr. D. B. BUTLER wished to heartily endorse the authors' remarks as to the general rectitude of the cement manufacturers in this country. A great many samples of cement passed through his hands for testing purposes, and the results fully bore out that opinion. Only one or two small makers used Kentish ragstone, and he believed that their product was used almost entirely for home consumption. He therefore wished particularly to emphasise this fact, because a report had been spread abroad, especially in our Australian colonies, that London manufacturers used adulterants, and such statements had most injuriously damaged the English trade in those colonies. He thought that the question of the effects of additions of gypsum had not yet been sufficiently thrashed out to be accepted without reserve. The authors' results were based on two samples, and at 28 days only, which was hardly sufficient to be conclusive. Undoubtedly the general effect of gypsum was to make a cement slower setting, and as it

was the growing practice of engineers to demand a very finely-ground and, at the same time, slow-setting cement—two qualities which were antagonistic in themselves—hence the necessity of gypsum. He had himself made experiments on the ragstone question, the results of which were embodied in a paper read before the Society of Engineers some 12 months ago, and, with some modifications, confirmed the statements of the authors. He found that an admixture of ragstone reduced the cementitious value of the cement in every instance, though sometimes when ganged neat the result was higher. He was disappointed to find that there had been no investigation as to the effect of the admixture of ragstone when used in sea-water and in air, especially as cement was used almost as much under those conditions as in fresh water. His own experiments showed that under such conditions the effect of the admixture was much more harmful. If, as the authors suggested, the only advantage of using ragstone was a certain slaking effect on the free lime in the cement, one might as well simply water the clinker. His own experiments as to the comparative effect of admixtures of ragstone and finely-ground sand proved that the advantageous action of the admixture was a purely mechanical one. In the table given by the authors on page 856 there was an average of only three briquettes at each date. That seemed to him a very small number on which to base an average; it would have been more satisfactory to have taken an average of five or six at least, especially in such an important investigation.

Mr. W. H. STANGER said that Mr. Butler was mistaken in supposing that the conclusions were based merely on the averages of three briquettes. Every result put forward represented two or three hundred tests, and thousands of briquettes had been tested in their series of experiments. It would have been impossible to have given the whole of the figures, so they simply selected typical examples. To those members who wished for further details he would recommend a reading of the full report of the Chamber of Commerce.

Mr. W. F. REID thought the Society was indebted alike to the authors for their contribution to this subject, and to the Chamber of Commerce for putting it at the disposal of the Society. With regard to the action of the Chamber, he noticed that two definitions of Portland cement were given, one at the beginning of the resolution and one later on, in the document which the manufacturers were invited to sign. He would like to know why these specifications differed. He, himself, regarded the addition of 2 per cent. of gypsum allowed by the second definition as being quite as much an adulteration as the addition of any *useful* substance to cement could be. He had met with cases in which coke containing a large percentage of ash was actually preferred by makers simply on the ground that it increased the output. With regard to the analyses, he would like to know whether the silica given at the beginning was soluble silica. Also whether the percentage of water had been taken into account. The addition of gypsum was not really necessary to render a cement slow-setting. Some German firms with which he was acquainted had abandoned that practice in favour of another process of manufacture which had the same effect. There were substances the addition of which to cement would undoubtedly prove beneficial, such as soluble silica, which would add to the hydraulic properties of the cement, and therefore enhance its value. The advantage of adding to the bulk by aeration was at least questionable; and he thought that cement should be used by weight alone, or if measured, then the weight of a given measure should be ascertained. The reason German makers had adopted a uniform sand was to obtain the most regular results—not the highest; and the same practice would be advantageous in England. It had been said that the beneficial action of ragstone—when it was beneficial—was due to the fact that it could be ground finer than the ordinary clinker. In that connection it would be important to know the composition of the finest portion of the powder mixture of ragstone and cement, as well as the composition of the residue on the sieve. In Germany, it had been recently proposed to grind the sand and cement together, and so they got greater strength of mortar.

Mr. E. Wood regretted that no users of ragstone were present to contribute to the discussion. If Mr. Blount were one of the audience, he would probably inquire whether it was reasonable to expect a thoroughly sound cement ever to be turned out for the recommendations of the Chamber of Commerce stated that a sound cement should have no ragstone in it, and therefore the natural corollary was that some might be added to a cement which was *not* perfectly sound. According to the diagram L, a 10 per cent. admixture bore a strain of 216 lb. at 7 days, and at 28 days a strain of 333 lb. But what would have happened if the test had gone on for ten days longer? Would not the 10 per cent. mixture have tested better than the undiluted cement?

The CHAIRMAN thought that it would be desirable that the authors should give analyses of the cements tested, for unless they knew their chemical composition it was difficult to judge the effect of the addition of ragstone to them. He would also like to have more exact definitions of the terms "sound cement" and "aeration." Did the former merely imply manufacture according to a standard specification? And could the advantage of increased bulk said to result from the latter be secured by mere mechanical means? If so, why let the cement lie for three months?

Mr. BEATRICE BLOUNT said that in mercy to the audience he would endeavour to reply as briefly as possible. Dealing with the Chairman's questions first, the subject of aeration was very interesting chemically. It was not merely a question of taking up water and carbonic acid. Le Chatelier had shown that water added to cement underwent transference from particle to particle until it had satisfied such compounds as were most eager for it. Such action could not be effected rapidly, and thus all attempts to effect it artificially had failed, simply because time was a necessary function. The chemical aspect of the question was too wide to be dealt with in a reply. A sound cement might be described as one in which the internal stresses which arose after the cement set were reduced to a minimum so small as to exercise no material effect on its strength. It was with a view to determine such stresses that hot tests had been devised. With regard to the number of tests and analyses made, as Mr. Stanger had already stated, the results brought forward that night were but an epitome of the work actually done. Although they had permission to do so, they did not feel justified in transferring the work bodily from their Report to the London Chamber of Commerce; and, moreover, to do so would have been wearisome. They had therefore selected typical cases. But if it would conduce to the better understanding of the subject they would be happy to incorporate the analyses alluded to by several speakers. He need not take up time in referring to Mr. Bamber's remarks, since they were in close agreement with the paper. He agreed with Mr. Matthews that it would have been better to carry the experiments further; but time pressed, and they had to pronounce as far as their data permitted. An ordinary test extended to seven days; they had adopted six months, and could therefore hardly be said to have erred from want of deliberation. No doubt longer tests were desirable, and should it be possible to make them, he trusted the Society would accord a hearing to the results. As to the increase of bulk by aeration, that was a matter which concerned contractors, who would now no doubt proceed to make the large profits said to accrue from additional turning. Mr. White had hit the nail on the head when he said that the chief use of ragstone was to "chock up the chinks." It was a body eminently adapted for that purpose; and tests with added powdered sand were not comparable, because the latter was a tougher article and did not "chock up the chinks" to the same extent. It grieved him greatly to have to differ from Mr. Hehner when he said that the addition of gypsum could not be detected. Mr. Hehner's reputation as an analyst was unsurpassed; and if he studied the question a little he would find it could be done. At any rate, it was done every day at Broadway, Westminster. He heartily concurred with Mr. Bloxam's remarks. It was matter of knowledge that one might take a cement, a tolerably basic material, with 92 per cent. of lime, and ignite it at a temperature of 1,100 °C., and expel almost the whole of the  $\text{SO}_3$ , thus arriving at an erroneous result for the true loss on ignition, *viz.*,  $\text{CO}_2$  and

$\text{H}_2\text{O}$ ; in fact, it was a matter of delicacy to adjust the temperature so as not to expel  $\text{SO}_3$ . Mr. Butler's reference to the number of briquettes had been dealt with by Mr. Stanger, and he could only add that if anybody had waded through the tests registered in three large folios, as he (the speaker) had done he would not think that too few had been made. With regard to the analyses of ragstone referred to by Mr. Reid, the composition was given in the dry state. The quantity of moisture had been determined, but was not recorded in the tables. It would vary a great deal. The water in the analyses was simply the combined water; and similarly the silica was combined silica after the ragstone had been decomposed by hydrochloric acid in the usual way. The quantity was insignificant, but it was necessary to determine it in order to ascertain if there existed in ragstone any silica capable of acting as a pozzolana. The analyses completely refuted any such idea. Mr. Wood's remarks as to an apparent discrepancy in the diagram, Series L., were not quite audible to him. If Mr. Wood would communicate with him, he would endeavour to clear up the point.

Mr. WALTER HEWITT, Managing Director of the Dartford Portland Cement Co., Ltd., sends the following remarks:—

The paper appears to place beyond doubt the fact that the action of Kentish rag or Portland cement is not in any way chemical, but purely physical and mechanical, and that this effect may be accounted for in two ways: firstly, by filling up the interstices between the particles of the cement it makes the mass denser, and by bringing into full effect the properties of each particle increases the strength of the cement. I am given to understand that other materials (such, for instance, as fine sand), if used in the same way (*i.e.*, added to the cement clinker at the crusher), would produce exactly the same effect. I do not know if the authors of the paper have experimented in this direction. If they have, it would be interesting to hear their experience. Should this be correct, it would be one more proof that there is nothing in Kentish rag to justify those who object to its being considered an adulterant. The second explanation advanced by the authors of the paper, of the apparent use, fulness of the Kentish rag is, that the moisture it contains slakes any particles of free lime there may be in the cement, and that its addition has thus the effect of aeration. This opens up a very big and important question, *viz.*, Should it ever be necessary to aerate or air-slake cement? The practice is frequently adopted in the case of highly-limed cements, *i.e.*, in cements which are manufactured with a large proportion of lime in order to attain a high tensile strain. Should any pieces of under-burnt clinker—known in the trade as "green" or "yellow"—be ground up with the rest, the effect is the same as if so much free lime were added, and it is to obviate any risk of this that engineers so often insist on the cement being thoroughly aerated before use. But are they not seeking a remedy in the wrong direction? Prevention is always supposed to be better than cure; and it ought not to be impossible to devise some means of ensuring the proper calcination of the clinker, and thus doing away with the tedious process of aeration. The same question crops up with regard to gypsum. The advocates of its admixture with Portland cement appear to rely mainly on the fact that its addition (up to 2 per cent.) is allowed in Germany. But there are two facts tolerably well known about German cements. One is, that most of them, if not all, are manufactured from various and different kinds of raw materials from those in England; and the use of gypsum may be rendered necessary by conditions which do not obtain here. The other fact is, that German cements, as a rule, attain their ultimate strength at a comparatively early date, and instead of toughening with age, like English cements, they merely harden and become brittle. This is a very serious defect, and it may not be very far-fetched to attribute it in part to the use of gypsum. But in any case I contend that gypsum is not necessary even here. It is added to retard the setting of the cement. It may be taken as a fairly general rule that a quick-setting cement is not to be relied on for hard wear, and it is an undeniable fact that a cement manufactured of chalk and clay in proper proportions, and *thoroughly well burnt*, will not set quickly, and, consequently, neither gypsum nor anything else is required to make it slow-setting. This brings me back again to my

former statement, that it would be well if some means could be devised for ascertaining that proper calcination of the cement had taken place. If this could be done, and a standard of test set up and accepted by engineers and the trade generally, both aeration, with all its attendant inconveniences and loss of time, and the addition of gypsum would become things of the past.

Mr. H. K. G. BAMBER (Messrs. Knight, Bevan, and Sturge, Northfleet, Kent) wrote to ask if Messrs. Stanger and Blount had made any experiments in the direction of adding gypsum to the raw materials during the manufacture of Portland cement, as distinct from what appeared to be the usual custom of adding it to the calcined clinker; and which was the method adopted by them for their experiments for this paper; and whether they had found that gypsum thus added, in the earlier stages of manufacture, which would of course be subjected to the extreme heat of the cement kiln, had the same effect in retarding the setting of the finished product. Some years since, when making some experiments on this subject of the adulteration of Portland cement, he found, as Messrs. Stanger and Blount had now done, that Kentish rag added to a good and perfectly sound cement only acted as a diluent, but if added to an overlimed cement, or one in the manufacture of which the raw materials had been badly mixed, thus preventing perfect combination during calcination, it had the effect of increasing the tensile strain at early dates, and perhaps partially counteracting for the time being some of the dangerous qualities which such cement would be certain to develop, and which of course would never be made a sound cement by such additions. While on the point of soundness, what did Mr. Blount consider the extreme and crucial test of soundness in cement? To be perfectly sound must it be capable of passing the stringent test introduced by Deval, or would it be sufficient if the cement failed under this test but was of sufficiently good quality to pass the less severe test now in vogue? He would like to have seen the comparative tests with and without the addition of gypsum carried to a much longer period.

In reply to the above communications, Mr. B. BLOUNT adds:—"It is certainly desirable that cement should be manufactured so as to require no aeration. This can be done if it be understood that cement-making is a chemical manufacture and needs skilled chemical supervision. The Deval test mentioned by Mr. H. K. G. Bamber is the best criterion at present known for the soundness of a cement, and those makers whose cements pass it may feel assured that their manufacture is more successfully conducted than that of makers whose cements fail to pass the test. The general adoption in this country of a test of admitted severity cannot fail to have the excellent result of putting our trade not only on a par but in advance of that of our commercial rivals abroad.

### AN IMPROVED ADJUSTABLE DRIP-PROOF "BUNSEN."

BY W. P. EVANS, M.A., PH.D.

THE writer feels himself compelled, by a recent publication of Dr. Hugh Marshall (this Journal, 1897, 395), to publish an account of a burner with which he has been working for some time past, although it is still in the experimental stage.

The main idea of the burner is a *side gas* combined with a *central air* supply (as in the Marshall burner) each being made as *axially symmetrical* as possible. The base of the burner consists of two turned metal cones which screw one over the other, allowing the gas to enter by the annular opening between them. Over these cones is situated the ordinary mixing tube. The bore of this tube is also carried downwards completely through the inner cone. The gas supply may be readily and accurately adjusted by means of the screw threads of the cones. In the *smaller* sizes the ordinary side holes may also be used with advantage to gain an increased air supply.

Details of construction are evident from the accompanying figure.

If the gas supply is constant the burner can be easily and economically constructed out of sheet brass, and the

cones fixed permanently in their right positions. The modification seems specially adapted for high-power burners, the short mixing tube necessary proving here a great

advantage. Instead of drip-proof it may fairly be called shower-proof, even a beaker full of water failing to put it out.

Meeting held on Wednesday, October 29th, 1897.

### CHAIRMAN'S ADDRESS.

#### THE MANUFACTURE AND PROPERTIES OF CARBORUNDUM.

BY CHARLES A. KOHN, PH.D., B.Sc.

THE wide range of temperature through which reactions can be studied to-day, is one of the most marked advantages of the conditions of modern experimental investigation. Chemical changes formerly unknown have been realised between the temperatures of solid oxygen and gaseous silicon.

In chemical industries the dissociation temperatures of the products of combustion from furnaces, as well as the fusibility of porcelain and other refractory materials, have limited the temperatures obtainable to 1,700—1,800° C. Platinum, which melts at 1,775° C., can be refined in the oxy-hydrogen flame, the temperature of which is about 2,000° C.—

the highest temperature obtainable before the introduction of the electric furnace. The temperature of the latter depends upon that of the electric arc. This Violle has estimated at  $3,500^{\circ}\text{C}$ .; and Moissan's experiments go to show that the actual temperature that can be attained in his various forms of electric furnace approaches this figure, and that it is a direct function of the intensity of the current employed.

The preparation of the metallic carbides, especially in a crystalline form, has been one of the most notable achievements of these new conditions of work.

It has been known for a long time that certain metals are able to take up varying and proportionately small quantities of carbon, but it has been reserved for Moissan to show, by means of his researches with the electric furnace, that the carbides form a well-defined group of compounds possessing very marked and novel properties.

Two of these carbides have already risen to the dignity of chemical industries—calcium carbide and carborundum; the energy of Niagara is now employed for both manufactures.

Owing to the kindness of the Carborundum Co., opportunity was given me to visit their works and to give you such details of the manufacture as might be of more than passing interest. For my information I am entirely indebted to Mr. E. G. Acheson, the discoverer of carborundum and the President of the Company, and to Mr. A. J. Fitzgerald, and I gladly avail myself of this opportunity of thanking them for the liberality with which they met all my inquiries, as well as for the care and trouble they have taken to enable me to illustrate this paper with specimens and photographs.

The experiments which led to the discovery of carborundum were undertaken by Acheson in March 1891. With the hope of obtaining carbon in a crystalline form, an electric current was passed through a mixture of carbon and clay placed in a carbon-lined iron bowl, the idea being that the clay, or the aluminium reduced from it, would dissolve the carbon and deposit it in crystals on cooling. The current employed was sufficient to fuse the mixture; a violent reaction took place, and a few hard blue crystals—not diamonds—were separated from the mass after cooling. A larger furnace made of refractory bricks was next tried, into opposite ends of which adjustable carbon rods were inserted as electrodes, and an alternating current of 100 to 200 amperes with an adjustable potential of 1 to 50 volts used. The crystals obtained were exceedingly brittle, but sufficiently hard when ground to a fine powder to abrade the diamond; from their colour and general properties, as well as from the materials used in their manufacture, they were regarded as composed of carbon and alumina (corundum), and named "Carborundum." This was in 1892 and before the product had been analysed. In the same year Schützenberger prepared amorphous silicon carbide (*Comptes Rend.* 1892, 114, 1089) by strongly beating a mixture of carbon and silica in a bone-black crucible, and showed that the green amorphous product formed had the formula  $\text{SiC}$ . The temperature of the furnace was evidently insufficient to allow of the formation of the crystalline carbide.

Acheson's early experiments, already referred to, soon led him to recognise the fact that the silica present in the furnace played an important part in the production of the carborundum, and direct experiment, in which the alumina was entirely omitted, confirmed this. A mixture of equal proportions of carbon and sand, to which 20 per cent. of salt on the total mixture was added, was found to give a largely increased yield of carborundum. The salt was added to facilitate the fusion of the mass. The furnace employed was considerably modified, especially with the view of overcoming the serious difficulty of starting the fusion of the mixture and of avoiding the continual changes in its internal resistance. These two objectionable factors were simultaneously eliminated by building a solid core of carbon between the two electrodes along the length of the furnace, and thus dividing the single arc previously used into a very large number of arcs of varying size and intensity, at the same time providing a conductor for the current. It is this arrangement that forms the essential

feature of the furnace now in use; it allows of the easy regulation of the current, and entirely avoids any possible electrolysis of the mixture.

A longitudinal section of the furnace is shown in Fig. 1. A represents the walls of the furnace, B the mixture of carbon, salt, and sand, D the core of granular carbon enlarged round the ends so as to surround the electrodes E, which are provided with copper connecting-rods C.

Fig. 1.

Longitudinal Section of Furnace.

The working of this furnace was a preliminary to the method now employed. It was sufficiently successful to establish the preparation of carborundum on a large scale. The details of the present conditions of manufacture can now claim our attention.

**The Raw Materials.**—These consist of coke, silica, salt, and sawdust. The coke is the ordinary beehive-oven product; the other ingredients call for no special comment. The salt acts partially as a flux, and also helps in the separation of the crusts of the different products that result in the manufacture. A considerable portion is volatilised. An addition of sawdust has been found advantageous, since the gases evolved during its carbonisation leave a porous coke, which serves to some extent as an exit for the carbon monoxide evolved. Formerly, sudden evolutions of gas occurred, forming "blow-holes" some distance below the surface of the mixture in the furnace, and often necessitating the removal of the overlying material; this is overcome by the addition of the sawdust.

These raw materials are delivered on the ground floor of the stock-house, a large building fitted with stages and elevators. The coke is roughly broken by a grinder, and then sorted by two cylindrical revolving screens. The coarsest portion is retained in the first screen, the remainder passing down a shoot to be ground to powder. The part kept back in this screen passes to a second similar screen, through the meshes of which the pieces, about  $\frac{1}{2}$  to  $\frac{3}{4}$  in. in length, pass, whilst the larger pieces are separated and ground with the finer portions from the first screen. The product which passed through the second screen is used for making the "core" of the furnace.

The ground coke, sand, salt, and sawdust, after being weighed out, are thoroughly mixed in a mechanical mixer. The following are the proportions used:—

Coke .....	34.2
Sand .....	54.2
Sawdust.....	9.9
Salt.....	1.7
	<hr/> 100.0

This mixture is now ready for the furnace. Two men can do the whole work of the stock-house required for 10 furnaces.

**The Furnace House.**—Ten furnaces can be accommodated in the furnace house; at present five are in use, which are worked successively. The sides of the furnaces are built up as each one is filled, and subsequently pulled down to allow of the removal of the carborundum, so that only the bed and ends of each furnace are permanent. This has been found advantageous, owing to the walls becoming incrustated and consequently to some extent conducting, when used repeatedly, thereby causing a decreased yield of carborundum. The furnaces, which are built of fire-brick, are 16 ft. long, 5 ft. wide, and about 5 ft. high. The ends are very solidly built, and about 2 ft. in thickness. In the centre of either end are the terminals, which convey the current through the central core of the mixture. These consist of 60 carbon rods, 30 ins. long and 3 ins. diameter, into the outer ends of which small pieces of  $\frac{3}{4}$ -in.

copper rod are fixed. A square copper plate, bored with 60 holes to receive the copper rods connected with the carbon electrodes, holds these latter in position. The carbons are placed in position from the inside of the furnace, starting with the bottom row, the spaces between the rods being packed tight with graphite as the fixing proceeds. The graphite packing prevents the oxidation of the carbons, and thus adds very materially to their durability. Each copper plate is provided with four projecting rods, to which the cables carrying the current are bolted.

Three rows of bricks are left permanently along the sides of the furnace, the remainder being built up as stated. At first the bricks are carried to a height of about 4 ft. Before putting in the mixture, iron screens are put round the inner ends of the furnace, about 4 ins. away from the carbon terminals, so as to keep the mixture from coming in contact with the latter. The mixture is then thrown into the furnace until it is rather more than half full, when a semicircular trench about 10½ ins. radius is made along the length of the furnace from end to end. Into this the weighed "core" is placed, a mixture of old and new core being generally used. The bottom of the trench reaches a little above the bottom row of carbons. The core is built up so as to complete the circle, forming thus a solid coke cylinder the length of the furnace and 21 ins. in diameter. To connect the core with the terminals, finely-ground coke is packed into the space between the carbons and the iron screens; next, the sides of the furnace are built up to the full 5 ft., the screens removed, and, finally, more mixture thrown in and heaped up to a height of about 8 ft. The furnace is then ready for use.

Fig. 2.

Carborundum Furnace, ready for Operation.

Fig. 3.

Carborundum Furnace at work, showing position of Carbon Terminals.

*The Electric Current.*—The favourable conditions for the supply of electrical energy at Niagara led to the erection of the present plant in 1895, the successful manufacture of carborundum having been previously worked out on a smaller scale at Monongahela, Pa.

The current as supplied by the Niagara Power Company has an electro-motive force of 2,200 volts. By means of a transformer this is reduced to 165 volts. The transformer has a maximum capacity of 830 kilowatts (1,100 horse-power); it is connected with a regulator, by means of which the current can be raised to 220 or lowered to 85 volts, and transmits an alternating current to the furnace. This reduction of the voltage involves a loss of about 4 per cent.; suitable cooling arrangements are adapted to the transformer and regulator to avoid overheating. Two copper conductors, each having a sectional area of 8 sq. ins., convey the current to the furnace room; these are bolted on to the outside copper plate of the furnace as described. The circuit is completed in the furnace room by means of a water rheostat, the ordinary methods of completing a circuit being too dangerous for such large currents as are employed in this manufacture. This rheostat consists of a circular iron vessel filled with salt water, into which a large iron plate is lowered by means of a pulley. To break the circuit, the plate is, of course, simply lifted out of the tank.

*Working of the Furnace.*—The charge of new mixture per furnace has gradually been raised, with improved conditions of work, to about 30,000 lb.; a considerable quantity of old mixture is also always used over again—sufficient to fill up the furnace. The core forms about 3 per cent. of the total charge; a mixture of new and old core is employed, the latter being added on account of its better conductivity.

After the cables have been bolted on to the plates of the furnace, the current is completed through the water rheostat in the transformer room, and the readings of the voltmeter and ammeter watched carefully. A pressure of about 190 volts is required in the start, but as the coke gets warmed the resistance decreases, and within an hour to an hour and a half becomes practically constant. As the current increases the regulator is run back, reducing the electromotive force, which is kept at about 125 volts till the end of the run. During this period the amperes increase from 1,700 to 6,000, and the kilowatts from 125 to 745. Very little regulating is subsequently required, but a very gradual decrease in resistance appears to be continuous, and is due to the formation of a layer of graphite immediately round the core, thus increasing the diameter and conductivity of the latter. This formation of graphite is regarded as due to the decomposition of silicon carbide after formation by the intense heat in this portion of the furnace.

The subjoined tables show the conditions of working now as compared with last year. In the early part of 1895 the energy expended per pound of carborundum made was about 7 kilowatt hours, whilst now it is only 3·9—a reduction of over 44 per cent.

#### Working of Carborundum Furnace.

Kilowatt hours .....	16,900	26,400
Kilowatt hours per pound ..	1·9	3·9
Pounds per hour .....	149·0	188·0

\* A considerable amount of old mixture was also used.

No immediate change is apparent on starting the furnace, but within half an hour the decomposition of the sawdust in the mixture is rendered evident by the smell. Carbon

monoxide is gradually evolved, and after three or four hours it comes off in sufficient quantity to be lighted, when the

Fig. 4.

sides and top of the furnace become enveloped in the flames. No less than 6 tons of this gas are given off during the run of a furnace. The equation representing the decomposition is:—

After 5 to 6 hours from the start, the progress of the working of the furnace is indicated by the appearance of the yellow sodium flames; fissures begin to form in the mass, and the upper portion sinks down as much as 3 ins. This decrease in bulk continues till the end of the run, but more mixture is thrown on as it proceeds, so that by the end of the run it reaches up to the top of the side walls of the furnace. From  $\frac{1}{2}$  to 1 ton extra mixture is thus added. After 36 hours the heating is finished. The current is then broken and the furnace allowed to cool for 24 hours. The length of run is considerably longer now than formerly; both the energy expended, and the rate of production are favoured by this change.

*Products obtained.*—After the furnace has cooled, the side walls are partially pulled down and the loose unchanged mixture on the top of the furnace raked off. This is used over again. Its composition is given below, and is seen by comparison to be essentially that of the original mixture, except that the proportion of salt is very largely increased—due, of course, to volatilisation from the hotter parts of the furnace.

Below this is a well-defined layer of amorphous carbide of silicon, with which varying quantities of unchanged mixture are mingled. This is the same product as was obtained by Schutzenberger, and, as the analyses show, it is practically pure carbide of silicon. The portions of this crust nearest the core are of a greenish tinge—due to the contained iron. On the outer portions of the crust the volatilised salt can always be seen. The amorphous carbide forms a readily friable mass of a dirty grey colour, and is easily removed, being first cut through with iron bars and then shovelled out. As yet, this product is entirely valueless—very unfortunately so, as it forms over 10 per cent. of the total carbide produced. Its amorphous nature is due to the relatively lower temperature of this portion of

the furnace, and it is the sole product obtained when the furnace is only run for a short time. It has not been found possible to convert it into the crystalline variety.

The change from the amorphous carbide to the carborundum is well marked, the latter forming a layer from 10 to 12 ins. thick round the core.

The outside of this crust of carborundum is first scraped clean with spades, then loosened with bars, and the carborundum dug out. The appearance of the mass when this crust is opened is exceptionally striking, the whole forming a glittering mass of brilliant crystals measuring up to half an inch in diameter and all beautifully iridescent. The colour varies from a steel-grey to a brown-green, and many of the crystals are quite translucent.

Below the carborundum is a thin layer of beautifully crystalline graphite, and a similar series of crusts obtain on the other side of the core. This formation of graphite is most probably due to the carbide taking up additional carbon when hot and re-depositing it as graphite on cooling, since many of the carbides prepared by Moissan behave similarly. The carbon of the core is partially converted into graphite also; this, too, is probably due to its having been taken up by the carbide and subsequently separated, for the quantity is not found to be appreciably increased even when the same core is used several times over.

Fig. 5.

Carborundum Furnace opened, showing Carborundum and Carbon Electrodes.

Fig. 6.

End View of Furnace after Heating, showing Carborundum and Core. (End wall specially removed for this photograph.)

One other product of the furnace is worthy of note. Tiny feathery tufts are often found sticking to the carborundum crystals, and occasionally the same product is found in larger quantity in the inner parts of the furnace in the form of pale greenish-yellow masses, excessively

light and extraordinarily like a fungus in appearance. On one occasion a piece quite 18 ins. long, about 1 ins. broad, and 2 ins. thick was obtained. At first this was regarded as volatilised silica, but it is really carbide of silicon in an extremely fine state of division. Under the microscope it appears distinctly crystalline, and consists essentially of perfectly transparent prismatic needles, amongst which a number of equally transparent hexagonal crystals were observed. The product closely resembles that obtained by Moissan by the combination of the vapours of carbon and silicon, and in all probability it has a similar origin.

**Working up of the Carborundum.**—This consists simply in grinding, washing with dilute acid, and sorting into different grades of fineness. The carborundum, as taken from the furnace, consists of various-sized aggregates of crystals. It is taken to a crusher, which consists of a large iron pan rotated horizontally by means of a vertical shaft. Attached to a collar surrounding this vertical shaft is a horizontal shaft, which carries two heavy iron rollers; the grinding action is aided by water placed in the pan with the carborundum. The ground mass is then transferred to large lead-lined wooden tanks, where it is treated with dilute sulphuric acid (1:2) for three days, the acid being heated by steam to 100° C. The iron and alumina are the chief impurities removed by this washing. 10,000 lb. of carborundum can be washed in each tank at a time. After leaving the tanks the carbide is thoroughly washed with water in a large rectangular tank. The finer portions, which are washed away by the water, are separately collected, whilst the remainder are thrown on to a drainer and subsequently dried on the outside of a small kiln. This portion of the product is finally graded through a system of screens. The finer powder washed away by the water is collected and dried in a similar manner and is known as "flours"; it is chiefly used for making hones and for polishing glass. "Hand-washed powders" are made by stirring up a quantity of ungraded powder with water, allowing this to settle for a certain time, and then pouring off the supernatant liquid. "10-minute powder," for instance, is one which separates from the liquid poured off from the original powder after it has been stirred up with water and allowed to settle for 10 minutes—i.e., a powder which remains in suspension for 10 minutes.

**The Composition and Properties of Carborundum.**—The carborundum as taken from the furnace and subsequently washed, still retains small quantities of iron and alumina, to which the varying colours, yellow-green and blue-green, are due. After treatment with acids and alkalis, heating in a current of oxygen to remove uncombined carbon, and finally treating with hydrofluoric acid, the carbide is obtained practically pure, as shown by analysis:—

A purer carbide of silicon has been prepared by Moissan, who obtained it in several ways. He found that the temperature of a wind-furnace, 1,200°—1,400° C., was sufficient to produce well-defined crystals from carbon and silicon, the latter acting as a solvent and the excess being subsequently dissolved away. By heating the elements in the electric furnace, yellow and occasionally sapphire blue, crystals were got, many of them quite transparent, whilst by bringing the vapours of carbon and silicon together in a special form of furnace, beautiful almost colourless

prismatic needles were formed. The following analytical results were obtained by Moissan (Compt. Rend. 1893, 114, 1089):—

	1.	2.	Theory for SiC.
C.....	63.70	63.85	70.00
Si.....	36.00	29.80	30.00

The carbon was determined by combustion with chromate of lead, the silicon by fusion with a mixture of potassium nitrate and carbonate.

Crystalline carbide of silicon has a specific gravity of 3.12. The faces of the crystals are usually smooth, with a brilliant adamantine lustre. The crystalline form is hexagonal, with the basal pinacoid predominant; exact measurements of the crystals have been made by Prof. B. W. Frazier, of the Lehigh University, who has confirmed the hexagonal symmetry of the crystals by optical examination.

The carbide is infusible and practically unaltered by prolonged ignition; heated to bright redness in a current of oxygen for one hour, the total loss in weight was only 0.41 per cent. Neither boiling hydrochloric nor sulphuric acid have any effect; even hydrofluoric acid alone or mixed with nitric acid does not attack it in the least. Sulphur is without action at 1,000° C. Chlorine at 600° C. acts very slightly, but at 1,200° C. complete decomposition occurs. When fused with caustic alkalis, the carbide is decomposed, silicate and carbonate of the alkali being formed. Lead chromate at a high temperature effects complete oxidation. The most valuable property of silicon carbide is, of course, its hardness. This lies between 9 and 10 in the ordinary scale, between the sapphire and the diamond, and certainly nearer 10 than 9, because the diamond itself can be undoubtedly polished by carborundum powder. This approach to the purest form of carbon by a combination of two elements so closely allied as carbon and silicon, neighbours in the periodic law, is exceptionally interesting. The synthesis of the diamond has only proved possible by allowing melted carbon to cool under increased pressure, under the ordinary pressure graphite always results; (Moissan). It appears, therefore, that the energy required for the formation of what is probably the more complex molecule is decreased when a portion of the carbon is replaced by a dissimilar element. This is not a function of the atomic weight, for carbon boride which has been obtained by Moissan (Compt. Rend. 117, 423), appears to be even more stable and harder than carbide of silicon; it forms brilliant black crystals, has a density of 2.51, and the composition B<sub>2</sub>C. Boron, like silicon, adjoins carbon in the periodic system of the elements. The properties and conditions of formation of a boride of silicon will therefore be of very considerable interest. In the carbon group of the elements the stability of the carbides decreases with an increase in atomic weight. Titanium carbide, TiC, which is not attacked by water at 700°, takes fire when heated to redness in oxygen; zirconium carbide, ZrC, is not decomposed by water at 100° C., but is readily attacked by hot concentrated nitric acid; whilst thorium carbide, ThC<sub>2</sub>, is decomposed by cold water, forming a mixture of acetylene, methane, ethylene, and hydrogen. Such considerations show, as Moissan has pointed out, that these carbides may play an important rôle in the classification of the elements.

**Uses of Carborundum.**—The practical value of carborundum is essentially as an abrasive, either in the form of powder or as wheels. For the latter the carbide is mixed in suitable proportions with clay and felspar, the mixture moistened, pressed into moulds, and then dried in kilns. Wheels from 36 ins. diameter down to the small dental wheels are thus prepared, various grades of carborundum being chosen according to the requirements of the work. For fine hones, rub-stones, and the like, other binding material is employed, whilst papers are prepared similarly to emery paper.

In these various forms carborundum is employed in the iron and steel industries, in the manufacture of pottery and

reclaim for smoothing up the "biscent ware" and for polishing granite. It is stated to be specially good for brass valve grinding, and is extensively used in the form of paper in the United States by shoe manufacturers for finishing the soles of shoes. The experiments made on the use of carborundum for polishing plate-glass have not been entirely successful, as, owing to its extreme hardness, the glass is scratched; but I am informed that a new method for polishing plate-glass allows of its advantageous use. A very interesting application is the use of barrel-shaped wheels for finishing hides and putting on the "nap."

In all these applications carborundum has to compete with emery, and for it to replace the latter its higher price—it is from two to five times as dear—necessitates very marked advantages. These advantages appear to be twofold. On the one hand it can work more quickly, and on the other it can do more work. Very many comparative tests have been made, and I believe I am well within the margin of possible error in saying that carborundum can do twice the amount of work of emery with a saving of 25 per cent. of the labour. In addition, in many instances, the work done is better.

In each application, however, the absolute advantages can only be judged by individual experience; so far, a continually increasing demand for carborundum has proved beyond a doubt that such advantages exist.

Uses other than mechanical may also arise; for instance, attempts have already been made to employ carborundum in the manufacture of ferro-silicon, but I have not heard with what success.

Our knowledge of the carbides of the metals is still in infancy, but I believe there is hardly an instance in which a laboratory curiosity has risen so rapidly to an important product of manufacture as has been the case with carborundum. Carbide of silicon is only six years old and the accompanying figures showing the increase in the production of carborundum and the decrease in cost, the latter resulting entirely from improved conditions of manufacture, are ample evidence that Mr. Acheson's discovery has enriched chemical industry as well as chemical science.

Meeting held on Friday, November 5th, 1897.

#### CHAIRMAN'S ADDRESS.

BEFORE speaking to you on the subject I have chosen for this, our opening meeting of the Session, I have, with sorrow, to mention the loss this Section has sustained since we last met, by the death of its Vice-Chairman Mr. Peter Hart, and also, quite recently, by the death of Mr. Thos. Jackson, one of the old school of vitriol makers of Clayton. Both had been with us from the formation of the Section, and indeed had much to do with its establishment, but Peter Hart was better known amongst us as the contributor of many papers to the Society's Journal, and by the general and willing aid he always gave when appealed to for advice. Peter Hart was the link binding the old school of practical chemists with the new school in the Manchester district, and his death deprives us of the pleasure which we should have had in seeing him presiding over us—which I had hoped would have come about after my term of office was over. I am sure we all may express our sincere condolence with his family to their loss.

To turn now to the immediate subject of my address "Recent Developments in the Chlorine Industry." The theme I have chosen has been taken in consideration of the fact that all the world is waiting to see what will be the outcome of the various installations which have been set up to make chlorine, and therefrom bleaching powder, by means of the electrolysis of common salt.

As you are doubtless aware, the proposition is by no means a new one—Charles Watt, in 1851, obtained letters patent (No. 12755, 1851) for a process for the decomposition of saline and other substances and for separating their component parts from each other by means of electricity. His specification is more than usually complete and shows how carefully he had worked out detail. He used a vessel divided into two or more compartments separated from each other by means of partitions of porous materials; he employed a Daniell's constant battery and the cells were fitted with movable hoods to conduct away the gases to where they were to be utilised. His *modus operandi* in the case of the electrolysis of common salt was to keep the brine saturated by adding common salt from time to time and when carbonates were required in the place of caustic alkalis, a current of carbonic acid was passed into the compartments which contained the eliminated alkali.

A second process described in the specification was that of converting the chlorides of the alkalis into hypochlorites and chlorates of the bases. Here again he is very minute in his instructions, which goes to show that his specification was something more than a mere idea.

Watt's specification was filed nearly half a century ago, and we may pause to inquire why the consummation of his invention has taken so long a period. Watt lived before his day, the dynamo is but a machine of yesterday and it certainly was not practicable to contemplate the use of such batteries as Watt describes, for the production of, say, hundreds of tons of bleach per week. Then again, it is easy to say in the description of one's invention "separated from each other by partitions of porous materials"—but the real invention would have been the production of such a partition of practicable size—which has not been accomplished until quite recently, although the energy of the whole electrical world has been concentrated upon the problem for many years.

No one, I believe, has ever doubted the possibility of the production of chlorine and alkali by the electrolysis of the alkaline chlorides, but its success as a lasting commercial operation depends entirely upon the pecuniary result. In a paper of no very ancient date, Dr. Ludwig Mond expressed the opinion that in many attempted electrolyses the operation would be found more costly than the existing or modified pyro-chemical methods. This may be so in isolated cases, but I do not think that the electrolysis of common salt is one of them, as industrial electrolysis is much nearer consummation than it has ever been yet.

Some inventors have found so much difficulty in securing a suitable porous diaphragm that they have endeavoured to separate the two ions by other means and thus it comes

about that practical electro-chemists are split into two schools, those who use other means than the diaphragm for keeping the ions apart, and those whose energies have been mainly devoted to perfecting the diaphragm itself, for as a matter of fact, this difficulty having been overcome the rest of the work is fairly plain sailing. The cost of the mechanical energy and the transformation of the same into electrical energy is now so well established and understood for all possible conditions that no difficulty should arise in this connection, and the question of current efficiency in chemical work may now be said to have reached that point when only percentage improvements are possible.

Granted then that these quantities are known, is it not possible, you will say, to accurately forecast what will be the result of a new manufacture on these lines? I do not think we yet know sufficient to do so, as it is not only necessary to make a profit on the new manufacture at present, but the articles produced must be made at a less cost than by any known method. My impression is that the electrolysis of chlorides is more costly than the simple calculations would have us believe if we may judge by the comparatively slow development of the electrolytic method for the production of chlorate of potash. Had the electrical method been so much cheaper than the existing methods, there is no doubt it would have been much more extensively adopted, as the production of chlorate of potash by this means possesses manufacturing, physical, and monetary advantages which no one can well over-rate.

If we say that one horse-power on a large motor should not cost more than a farthing per hour, that only 10 per cent. of the mechanical energy is lost in transforming it into electrical energy and that the current efficiency is 90 per cent. of the theoretical, then we may take it that, with any reasonable length of run with the diaphragm and with present selling prices, the result of the manufacturing operation should be a profit. The extent of that profit it is almost impossible to forecast, but I am very strongly of opinion that bleaching powder, the hydrochloric acid included, can be as cheaply made by existing processes as is possible by any electrolytic method.

The difference between the electro-decomposition of salt and its decomposition by sulphuric acid lies in the fact that in the former case two valuable products are formed, the alkali or its carbonate on the one hand and the chlorine on the other, while from its decomposition by sulphuric acid only one valuable product is produced, the chlorine—the resulting salt cake being actually a drag on the process seeing that it costs about 36s. to produce, and only realises 18s. in open market. If salt-cake should ever again rise to a remunerative figure, of course the position would be changed, but are there any hopes for such a change? I am afraid not, and the only salvation of the alkali trade is in the production of as little of it as possible. At the present moment at least two tons of salt cake are produced for every ton of bleach made by the manganese process which means a reduction of at least 36s. per ton from the revenue of the manufacture, whereas in the electrolytic method the by-product is a solution of caustic soda or its carbonate which adds something to the revenue.

As I have pointed out in a previous address to you, a solution of the foregoing evils has been attempted by the introduction of the Hasenclever improvements as an addendum to the Deacon chlorine process, but this is only a partial relief, as there is still the loss on 20 cwt. of salt cake per ton of bleach to be reckoned with, and, further, the nitric acid chlorine process which still further reduces the salt cake, has come to stay. In actual practice, this process turns out to be more easy of manipulation than was at first anticipated, but nevertheless it appears necessary to east about for some chemical process by which the production of salt cake will be suppressed altogether. And why? Because the uses for salt cake are very limited, and should the price rise to make the manufacture *per se* a profitable one it would be brought into contact with ammonia soda which would be found to answer the consumer's purpose better, and the consumer would never revert to salt cake unless its price was substantially lowered again. Roughly, three parts of salt cake will only do the same chemical work in glass-making (now its principal use) as

two parts of ammonia alkali, and as there is now a large quantity of ammonia soda selling in the States at 12 dol. per ton (2l. 10s.) the price of salt cake at 33s. 6d. per ton exceeds the economical ratio.

You will be saying, perhaps, what are these electrolytic processes and how near are they to financial success? The representative of the no diaphragm school is the Castner Kellner Co. with its works at Weston Point near Runcorn, and it is stated that the installation is decomposing from 45 to 50 tons of salt per week, but it is too early yet to speculate upon the financial success of the operation. The representative of the diaphragm school is the Hargreaves-Bird process which seems now to have established its *raison d'être*. A practical working cell capable of turning out one ton of bleaching powder per week and its equivalent of carbonate of soda is in operation at the company's works at Farnworth, but I am not able to give you any financial results, though it is very probable that a much more extensive installation will soon be completed. But as I have already pointed out, it will not be sufficient for these processes to demonstrate that it is possible to produce chlorine and alkali as a practical operation, or even to have a mean balance of revenue over expenditure. If they are to compete with the older processes, they will have to produce bleaching powder at less cost considerably than is being done now. As the markets new stand, the manganese process is scarcely in the running, though if the salt-cake difficulty should be overcome, it is a process difficult to beat with regard to cost.

The two processes which will compete closely with electrolysis, as far as bleaching powder is concerned, are first the Deacon-Hasenclever, and second the nitric acid chlorine processes, and we may now consider the cost price of bleach made by them both.

More than 50 years have passed away since Robert Oxland obtained letters patent for decomposing a mixture of hydrochloric acid gas and air by passing the mixture into a furnace filled with pieces of porous pumice-stone and kept at a bright red heat. Such a process, without the perfection of details as we know them to-day, could not possibly compete with the manganese process, and it is even now doubted by many whether, with the Hasenclever improvements, the method could hold its own with the Weldon process if salt cake were to rise in price.

The method now followed in the most recent works is to pass the hydrochloric acid gas (mixed with air) from two or more salt-cake pots, first through a drying tower down which sulphuric acid is made to flow, and then through a series of towers of peculiar construction, where the mixture comes in contact with heated cupreous material, and where decomposition takes place to a greater or less extent according to the chemical and physical conditions. The mixture of chlorine and hydrochloric acid is then washed with water, which dissolves out the hydrochloric acid, and the chlorine being dried by another sulphuric acid tower is passed into absorbing chambers of the shelf pattern. The liquid hydrochloric acid is then treated with sulphuric acid by the method described by Isham Baggs (British Specification 3269, 1866), mixed with air, and sent through decomposers, as was the pot acid. It must not be forgotten that it is only the pot acid that is decomposed directly: the roaster acid is condensed in water and treated with sulphuric acid to retain the water. It will thus be seen that the Deacon-Hasenclever process has nothing in simplicity of plant to recommend it: in fact, when compared with the Weldon process, it is a labyrinth of complications. Besides the ordinary vitriol and salt-cake plant, with the necessary muriatic towers, there is the vitriol-frying tower, the preliminary heater, the decomposing towers, the water-wash tower, and the vitriol-drying tower, before we come to the chambers where the chlorine is absorbed: then there are the Hasenclever cylinders and the decomposers relegated to them, with the pans required to concentrate the weak acid—a lively prospect when almost theoretical results are necessary to yield a profit.

An analysis of the operations necessary in this process do not impress one with its simplicity any more than the plant does. In a works making chlorine equivalent to 100 tons weekly of bleaching powder, certainly not less

than 150 tons of water have to be evaporated from the Hasenclever pans, and the whole of the water in the oil of vitriol used for salt-cake making is also collected in the vitriol from the drying tower, from which it has to be subsequently evaporated. I am not specially urging these facts as any great objection, but in coming later on to the cost you will be able to better appreciate the figures if a rough outline is given of the operations and their quantities. The 150 tons of water mentioned above, when added to oil of vitriol of 145° Tw., will produce nearly 1,200 tons of weak acid of 120° Tw. for evaporation weekly.

I think we may take it that 18 cwt. of salt are required to produce a ton of bleaching powder by the Deacon-Hasenclever process. It is true that short runs have been made at less than this, but, taking all in all, 18 cwt. will be found a very fair average, and this means the production of 20 cwt. of salt cake. Now, the salt cake made in the Deacon pots costs more to produce than ordinary salt cake, as the pots have to be humoured more according to the flow of gas required. It is nothing uncommon to produce 500 tons of salt cake per week in an ordinary pot and furnace, whereas with the one under consideration it is much less than this figure—probably between 40 tons and 50 tons, or perhaps even less.

From the latest statistics of the most modern works, I gather that the actual manufacturing cost of Hasenclever bleach for manufacturing wages (other than salt cake or O.V.) for lime, for fuel, for cupreous material, for casks, for loss of sulphuric acid in the process, for repairs which are very heavy, and for the loss on the manufacture of 20 cwt. of salt cake cannot be less than 4*l.* 6*s.* 9*d.* per ton. No allowance is here made for the general expenses of the establishment and no one but he who has gone through the mill can imagine how quickly but surely these tell up. There are the rent, rates, and taxes, miscellaneous labour that cannot well be charged directly, carting and waste deposit, forwarding charges, consul's certificates, telegrams, telephones, commission, sampling fees, gas and water, insurance both of works and material, office charges, laboratory expenses, law charges, auditing charges, expenses of management, estate charges, and last, and not least, there should be provided at least 5 per cent. interest on the capital invested, or the same amount as provision for those who have supplied the wherewithal. Taking all these items into consideration, I shall not be far out in considering that they will amount to twenty shillings per ton of bleach if bleach only is made, so that Deacon bleach should be sold at more than 5*l.* 6*s.* 9*d.* per ton before there is any chance of setting aside anything for depreciation. This is the cost of Deacon Hasenclever bleach, and it is this sum that the electrolyzers will have to beat before their labours can be deemed successful.

With respect to the new comer—nitric acid bleach—I do not wish to enter into details at the present moment. It is my intention to offer you a paper upon the subject so soon as my term of office as your chairman is over, and I venture to think you will find the subject interesting. I can, however, tell you that a ton of nitric bleach can be made for much less than the 4*l.* 6*s.* 9*d.* mentioned in the foregoing example, including the loss on the manufacture of 16 cwt. of salt cake. Weldon bleach cannot be made for less than 4*l.* 16*s.* 7*d.* actual manufacturing charges, including loss on salt cake but without any charge for the general expenses of the establishment which would bring up the figure to 5*l.* 16*s.* 7*d.*

These figures show what a small margin is left to the maker of bleaching powder and the near future will show us how much more cheaply the electrolytic method can produce, if at all, but we must not lose sight of the fact that the two processes are not identical. While the electrolytic method is producing chlorine, it is at the same time liberating alkali. In the Castner-Kellner process it is worked as a caustic solution and made into caustic soda, while in the Harpaves-Bird process it becomes carbonate of soda.

To show you the extent to which the electrolysis of salt is now carried on in England it may be received as correct, that the Castner-Kellner Company at Weston Point is turning out 70 tons of bleach and 30 tons of caustic soda

weekly. The plant is being duplicated in order to produce 140 tons of bleach and 60 tons of caustic and all arrangements are made to follow on with another two sets which will bring the production to 280 tons of bleaching powder and 120 tons of caustic soda weekly by July next.

Before leaving this subject I would like to put before you the cost of bleach making by the Weldon process in 1875 at a works not many yards from where the electrolysis of salt is now being effected.

*Memo. of the cost of making 2,480 tons of Bleaching Powder by Weldon's process from July 1st to December 31st, 1875.*

	Per ton Bleach.	
	£ s. d.	£ s. d.
Manganese, 70 per cent., 197 tons.	0 7 11	300 16 10
Freight on ditto at 1 <i>s.</i> 3 <i>d.</i>	0 0 1	13 2 8
Powder lime, 1,532 tons at 17 <i>s.</i> 8 <i>d.</i>	0 10 10	1,352 18 2
Pot lime, 1,480 tons at 17 <i>s.</i>	0 10 2	1,263 1 6
Limestone dust, 1,117 tons.	0 4 3	529 3 6
Slack, 3,221 tons at 6 <i>s.</i> 2½ <i>d.</i>	0 8 1	1,003 15 8
Casks (hardwood) and cooperage wages	1 6 0	3,224 0 0
Process wages	1 3 3	2,880 19 11
Repairs wages	0 4 3	531 11 5
Materials for repairs	0 5 4	660 5 5
Sundries	0 1 4	174 16 4
	5 1 6	

The figures show pretty well what was capable of being done 22 years ago, but these were not all the expenses. There were other charges over and above the foregoing and which amounted to no less than 17*s.* per ton of bleaching powder.

At this time (1875-76) salt cake which cost 46*s.* per ton to make was selling at 55*s.*, while bleaching powder stood at 7*l.* 10*s.*, and nitre cake, which in some localities can now be had for the asking, could not then be purchased under 35*s.* per ton. There are two ways at least of looking at the present position of the alkali trade. The late Mr. Weldon, in a pamphlet published so late as 1883, said "The inevitable result of the rapidly increasing competition of the ammonia soda process must be that the English Le Blanc soda maker must either sell his bleaching powder at 7*l.* 16*s.* 5*d.* or close his works." Now the English Le Blanc maker of the present day does neither of these things. Why? Because not only have the manufacturing ratios been changed but economies have been realised which even Mr. Weldon declared impossible, and the prices of raw materials have been considerably cheapened. The position in 1883 when the Weldon pamphlet was written was thus stated: "To obtain the quantity of hydrochloric acid at present required for the production of a ton of bleaching powder one must manufacture 55 cwt. of sodium sulphate." The position to day is that one need not manufacture more than 44 cwt. even by the manganese process; 20 cwt. by the improved Deacon; or 16 cwt. by the nitric process.

By the Le Blanc process, the manufacture of vitriol salt cake and bleaching powder must be taken as meaning one manufacture and if the salt cake is sold rather than used, the selling price will enable one to readily discover the deficiency that accrues from the operations. One way to bring this deficiency into £ s. d. is to assume the production of so much liquid muriatic acid at the market price and to credit the salt-cake department with this amount. This method of reckoning out costs is more or less correct according to what is done with the products. If salt cake and liquid muriatic acid are sold we need not find fault with the process, though in many cases the cost of filling the earboys and consequent tear and wear are too often left out of consideration. At the present moment the average production of 30° Tw. muriatic acid is 36 earboys (10 gallons) per ton of 90 per cent. salt and its value 7½*d.* per earboy in buyers' packages.

The other way of reckoning is to take the difference between the manufacturing price and the selling price of salt cake and to add this to the manufacturing cost of the bleach; but both methods are unsatisfactory and tend to show the artificial state of the industry.

This is the present condition of things as found by electro-chemists on their entry into this field and moreover they find a depressed market—a market in which any extra quantity of bleach is disposed of with difficulty. Philanthropists will, however, be glad to know that the electrolytic works have already given to the consumer a substantial part of what might have been profit, as a keen passage of arms has been going on between them and the amalgamated companies of the old school and orders have been fought for with more zeal than discretion. How long this will go on no one can tell, but does it not recall to memory the old cartoon wherein the lawyer and the two litigants are dividing their property in an oyster. There may be some doubt as to whom the oyster will eventually fall, but there is no doubt at all as to who will be left with the shells.

For several years now, chlorine has been produced from the electrolysis of chloride of potassium, and bleach, as well as chlorate of potash and caustic potash, have come into the English market. In fact, electrolysis of this muriate threatens to completely overturn the caustic potash and perhaps the carbonate of potash industry. By the electrolysis of 98 per cent. muriates caustic potash of much greater purity than that made by the old process can now be obtained and at a price less than was formerly charged for the impure article.

As to the progress of electrolysis as a standing manufacturing process we must ever admit the possibility of improvement and it is possible that other chlorides than those of sodium and potassium may in time be made to produce a cheaper bleach. The metallic chlorides offer many advantages over the alkali chlorides as will probably be discovered ere long, and the competition for orders, especially in the home market will most probably give even electrolyzers a taste of bad times similar to those which the Le Blanc alkali trade has passed through. No one now has any prescriptive right to the use of mercury and no one can claim sole proprietorship in the use of a diaphragm, and once the electrolytic fever has fairly set in we shall have new calls and modified methods of working by the score, and only those will benefit who manage to get a good round sum for their supposed inventions from credulous shareholders in search of a cent per cent dividend.

It is a great pity some of our old inventors and patentees are not with us now, a Weldon, a Gossage, a Deacon, or even a Tessié du Motay would have made the Patent Office fairly hum.

We have quite recently had a foretaste of the things that will happen, in the case of a newly devised electrolytic cell which was ushered into existence by a grand parade of viands and select after-dinner speeches, and there is no limit to the extent to which this process may be carried, but those will suffice least who weigh well all the advantages or otherwise of the newer forms of apparatus side by side with those of older pattern.

We may now turn to another phase of the question. How will the electrolysis of salt affect the soda industry? I have already suggested, though not stated in so many words, that the diaphragm method is not specially suited for the production of caustic soda, mainly on account of the short life of the diaphragm in caustic solutions of any reasonable strength. This fault is eliminated in the mercury method, so that, at present at least, we may infer that caustic soda will be made by the Castner-Kellner process, and carbonate of soda by that of Hargreaves and Bird. If caustic soda be a first product and of a greater value than carbonate there is no reason in converting it into a low-priced article while this fact may be a stimulus to the invention of those in charge of the diaphragm plants.

Le Blanc caustic soda is now being made in Widnes and elsewhere from salt cake, but the industry is slowly dying a natural death being only kept alive by reason of the abnormally low price of salt cake. Caustic soda is also being made by Löwig's process, viz., that of calcining carbonate of soda with ferric oxide, and it is further produced by the causticisation of ammonia soda. Of the three processes there is no doubt the third is the cheapest when properly performed, but can even it compete with the caustic soda from electrolysis, which is in reality a by-product? I have heard it stated on what should be good authority that

caustic soda can be made by the electric method for less than 50s. per ton, but this, of course, will depend upon the selling price of bleach, and the knowledge of some such cost price, as this will not only stimulate the Le Blanc makers to exertion but even the ammonia soda makers will have to look to their laurels. Specially does this remark apply to the English makers for the markets of the world are no longer their special customers. Continental caustic and even ammonia soda has found its way into London as the continental makers produce more than is required for their home consumption, and America is now producing largely both ammonia soda and caustic soda prepared from it.

But even in the States ammonia soda and its products may suffer by competition with electric soda seeing that the Matheson Company hold the patent rights of the Castner-Kellner Company for that part of the world. This has not come about yet, though, seeing that the Michigan Alkali Company have at Wyandotte, near Detroit, one of the largest caustic soda works in the world in full operation, it will not be long before a trial of strength occurs between them. I ought to be careful to state that in all these probable changes there is much uncertainty; the selling prices of both bleach and caustic might not always be regulated by the ordinary laws of supply and demand, and should the large companies not be wholly satisfied with their insane policy of "war to the knife" the position would have to be discounted in the light of a probable coalition. Anyhow, I believe there is no bright outlook for anyone producing ammonia soda or any of its products. Once given caustic soda or its carbonate as a by-product, first soda crystals will suffer (always supposing the bleach to be the main object sought for and its manufacture *per se* profitable) and then bicarbonate, as there is no reason to suppose that so profitable a product as this will remain long unassailed.

We move rapidly now-a-days, if it takes but 10 years to make countries such as those of which Salisbury and Bulawayo are capitals we may expect a decade to see the rise and fall of many a new chemical industry. A year has scarcely passed since the first sod of the Michigan Alkali Company's works was cut, and to-day they are producing 100 tons of caustic soda weekly and the first installation will be quadrupled before the end of the present month. An output of 400 tons per week is not one to be despised, and will, I fear, play sad havoc amongst the manufacturers here.

Before concluding this address I would like to enter a protest against the statement that the manufacture of bleaching powder is a growing industry in England. It is no such thing judging from the number of factories out of use, some pulled down and others only working half time. I should say it is a declining industry, and every ounce that is made by any new process will have to be placed at the expense of an equal quantity made by older methods and consequently every ounce to be sold will be fought over with a zeal deserving of a better object. If I had to advise the investor I should say "don't" and seeing that chemicals, as a rule, are likely to be cheap, in fact below cost price generally, I ask would it not be better to seek investment in a consuming rather than a producing chemical business?

SESSION 1897-98.

Dec. 17th.—Exhibition of New or Improved Apparatus for Chemical Work.

*Meeting held Thursday, November 18th, 1897.*

PROF. HENRY LOUIS IN THE CHAIR.

## FLOCCULATION AS AN AID IN LABORATORY WORK.

BY R. GREG SMITH, M.Sc.

THE flocculation of clay and the sedimentation of mud have been treated by several writers in the last number of years, and it has been shown that many salts, bases, and even acids have the power of causing the coherence of small solid particles into aggregates, which comparatively quickly settle down in water. In the practice of agriculture, lime has long been used with success upon clay soils to increase the tilth. This it does by inducing the microscopic particles of clay to adhere closer together, and as a result, the soil water, which could only pass between the particles with difficulty, owing to the great friction produced, runs more freely through the channels between the aggregates; the soil becomes less plastic, drier, and better suited for the growth of crops.

This phenomenon has been shown (Proc. Chem. Soc. 1891, 176) to be practically identical with the coagulation of colloid bodies by electrolytes. In some excellent papers on "Solution and Pseudosolution" (Trans. Chem. Soc. 1892, 160; and 1895, 63), Messrs. Picton and Linder have demonstrated that all electrolytes have not the same coagulating power, and consequently, since coagulation is so closely allied to flocculation, it follows that some salts will act better as flocculating agents than others. From their experiments, Messrs. Picton and Linder conclude that the "tervalent metals have the highest coagulative power, bivalent metals about one-tenth of this power, and univalent metals, including hydrogen and ammonium, less than one five-hundredth"; ammonium salts are more powerful than potassium, and the latter are stronger than sodium.

In the discussion which followed the reading of the first paper, Mr. Herbert Jackson called attention to the fact that coagulation was similar to the phenomenon observed during the washing of many precipitates, such as lead hydrate and silver nitro-prusside, which furnish turbid solutions and refuse to settle when the liquid in which they are suspended approximates to pure water, but which flocculate when a drop of saline solution, as sodium acetate or potassium nitrate, is added.

The use of flocculating agents does not appear to be so generally known as it might be, for in the various methods of analysis one is sometimes advised to add this, that, or the other salt. The reason for so doing is sometimes given, but a choice of flocculating agents never is; and it is with the idea of altering this rule-of-thumb state of things that I have ventured to collect and bring before you a few examples of flocculation and of coagulation. At the same time, a few suggestions are made which I trust may be useful.

What is usually admitted to be one of the most troublesome substances to filter is barium sulphate precipitated from a solution of chlorides. It is frequently recommended to have the hydrochloric acid in considerable excess, and to boil the solution for some time. Instead of the hydrochloric acid being present in quantity, ammonium chloride may be used with precisely similar results; but surely it is only a little extension of the principle to suggest that ammonium chloride, or better, perhaps, ammonium nitrate, would be a good substitute for water in washing the precipitate on the filter. Since Messrs. Picton and Linder have shown that the precipitates carry down traces of the flocculating base which cannot be washed away by water, it follows that non-volatile salts cannot be employed where the precipitate has to be ignited and weighed, and consequently in such cases only salts of ammonium and the acids are permissible. But they have also shown that the firmly adhering base of the coagulant may be displaced by the mass action of other bases, and therefore, in cases where non-volatile salts have been used, the objectionable base may be eliminated by subsequent washing with solutions of acids or of ammonium salts. If precipitation, even, has

taken place in presence of non-volatile bases, water is not sufficient for the elimination of the adhering traces of these, and recourse must then be had to solution and reprecipitation, or to the quicker washing with a volatile electrolyte. These fixations and replacements recall the fixation of bases by basic silicates and by double humates in the soil.

In the determination of phosphoric acid, the precipitated phosphomolybdate of ammonia is washed with diluted molybdate of ammonia solution, dilute nitric acid, or with a solution of ammonium nitrate, in order to prevent it passing through the filter paper. Of the three bodies, ammonium nitrate lends itself best for this purpose, since, owing to its neutral reaction, the yellow precipitate is sooner dissolved in ammonia, and, moreover, a smaller volume of filtrate is obtained. When, however, large amounts of iron are present, as in the nitric acid solution of soils or basic slags, the ammonium nitrate should be acidified with nitric acid, and it is well to have a little ammonium citrate dissolved in the dilute ammonia subsequently used in dissolving the phosphomolybdate. The addition of ammonium nitrate to the stock solution of molybdate, to the extent of 10 per cent., not only assists the precipitation of the ammonium phosphomolybdate, but also prevents the precipitation of yellow molybdenum trioxide, should the reagent be kept for any length of time.

Silver chloride is generally precipitated in presence of an excess of free nitric acid, which causes the precipitate to collect in large flocks, and any tendency which these may have to break down, and pass through the filter paper can be checked by using water acidified with nitric acid for washing instead of ordinary distilled water. In the volumetric estimation of chlorine by direct precipitation, a few cubic centimetres of a solution of aluminium nitrate will be found to be more useful than nitric acid, since it causes a better coagulation, the flocks are denser, and the fluid becomes clearer, so that the end of the reaction is more easily seen.

There is rather an anomalous case in the estimation of manganese by precipitation with permanganate. Zinc salts are added and the liquid kept hot to "regulate" the precipitation of the dioxide. It seems to be a case of coagulation or flocculation, since iron salts may be substituted, but, curiously enough, neither aluminium nor barium salts are said to have the same desirable effect.

In the separation of nickel and cobalt qualitatively, by means of potassium ferrieyanide and ammonia, the operation is greatly facilitated by the addition of an excess of ammonium chloride to the slightly acid solution of the two metals. The cobalt ferrieyanide becomes much denser and does not run through the filter.

In the extraction of chlorides and nitrates from large quantities of soil, the exhaustion, with a dilute solution of a suitable flocculating agent, such as potassium sulphate or lime water, will not only counteract any tendency which the clay particles may have to pass into the extract, but also, by maintaining the flocculated condition, enable the extraction to be quicker and better made.

The appearances of small quantities of calcium oxalate, when precipitated in the presence and in the absence of excess of ammonium salts, are sufficient to show that these flocculating agents are decidedly advantageous, and should they be also used in the washing, the floccules will be maintained, and there will be little tendency for the oxalate to pass through the filter paper.

Thus far in these examples the flocculating or coagulating agents have been used in neutral or in acid solution. A considerable number of our precipitates, however, are effected in presence of alkaline hydrates, or of salts with an alkaline reaction. The hydrates or basic salts of the metals and the earths act as flocculating agents, while, on the other hand, the hydrates of potassium, sodium, and ammonium appear to prevent flocculation to a greater or less degree. Fortunately the metallic hydrates or basic salts, which are the precipitates generally obtained by the action of the stronger alkalis, are gelatinous, and to a certain extent self-contractile, especially in the heat.

The effect of alkalis is perhaps best seen in their action on soils, or on clay particles suspended in water. The

alkalis, alkaline carbonates, phosphates, and oxalates prevent sedimentation, while lime, as a type of the earthy hydrates, is one of the best flocculents which we have. The action of the neutral phosphates and oxalates of the alkalis in preventing flocculation can be explained by the production of an alkaline solution through the double decomposition which will ensue between these and the lime, magnesia, &c. present in combination with basic silicates and double lumates.

Only in one place in Messrs. Piéton and Linder's papers can I find any mention of the action of alkalis on flocculation, and that is in connection with Congo red. In alkaline solution it was, in contrast to its behaviour in neutral and acid solution, found to be filterable through porous earthenware. Evidently in alkaline solution Congo red does not consist of such large molecular aggregates as in neutral or acid solutions, and consequently is not so easily coagulated.

Examples of coagulation by means of metallic hydrates are to be seen in the coagulation of albuminoids by copper hydrate (Stutzer's reagent), of colloid organic matter by basic lead acetate, and by basic aluminium and iron salts in the formation of lakes and precipitation of sewage. It is true that this coagulation may be explained by the formation of insoluble double compounds, and so be made to appear quite distinct from flocculation, but a sharp line cannot be drawn between the two phenomena. Once the coagulating hydrate is removed, the organic matter, unless it has been altered as with the albuminoids, generally becomes again soluble, just as when the flocculating agent is washed away the floccules are destroyed and an emulsion-like condition produced.

Organic matter contained in some alkaline solutions—as, for example, the aqueous extract of farmyard manure—can be readily removed by the addition of a few drops of a solution of aluminium sulphate. The organic matter in the almost black solution coagulates at once, and the clear colourless liquid can be readily filtered and washed, or the whole solution made up to some volume, filtered through a dry filter, and an aliquot portion taken for the estimation of chlorides or nitrates.

The power of the alkalis in preventing flocculation may be minimised by the simple process of taking care not to add an excess of alkali or by adding a considerable excess of some flocculating agent.

As an instance of the former case, take the precipitation of zinc as sulphide by the method of Jean Meunier, lately abstracted in the *Journal of the Chemical Society*. The author adds ammonia carefully till the precipitate is just redissolved, and passes sulphuretted hydrogen through the solution till precipitation is complete, as indicated by testing the solution with ferrous sulphate. "The precipitate is readily filtered and washed, especially if the liquids are warm. The precipitate is not interfered with by relatively large quantities of ammonium salts." In this process, a minimum amount of alkali is employed; there is no excess of ammonium sulphide—the sulphides and especially the polysulphides retard flocculation strongly—and there may be large quantities of ammonium salts. With regard to the latter, it may be said that ammonium salts certainly do not interfere with precipitation; they rather assist. That they do so can be shown by possibly one of the best examples of their action in alkaline solution.

A dilute solution of a nickel salt is taken, saturated with sulphuretted hydrogen, and treated with an excess of ammonium hydrate. The sulphide so produced is filtered with difficulty, and the filtrate is generally coloured. Should, however, half of the unfiltered liquid be treated with an excess of ammonium chloride, flocculation is soon apparent, filtration can be easily effected, and a clear filtrate obtained. The use of ammonium chloride in this way has been found exceedingly useful in the laboratory, when separating the metals of the iron group qualitatively.

But the action of ammonium salts, which appear to be the best flocculating agents in alkaline solution, can be shown in a more commonly occurring case of precipitation, viz., that of ferric hydrate. A solution of ferric chloride, when treated with an excess of caustic potash in the cold, gives a gelatinous precipitate. Should an ammonium salt,

as ammonium nitrate, have been previously added, the precipitated hydrate is clearly less gelatinous; it settles better, contracts more on warming, and filtration, in consequence, is much more rapid. In continuation of this idea, one finds that washing the precipitate with ammonium nitrate in some cases causes a faster filtration. There is no doubt, however, that when the precipitation is effected in the presence of the flocculating agent, the results are far superior to any subsequent attempt at flocculation. Although by the washing with ammonium nitrate, filtration may not always be faster than when water is employed, yet the precipitate is always sooner freed from adhering alkali. Salts of potassium and sodium, so far as the coagulation of ferric hydrate is concerned, do not seem to have much effect in presence of their hydrates. This is at variance with what has been observed in the volumetric estimation of sugar. In using a Fehling's solution made with caustic soda, the reduced cuprous oxide can be made denser, and the end reaction can be better seen by the addition of two or more grammes of potassium sulphate per test. In preparing the reagent, however, caustic potash is to be recommended in place of caustic soda for giving a more compact precipitate. The heating and the relative density of the solutions will probably account for the observed difference in the action of potassium salts upon the condensation of ferric hydrate and of cuprous oxide.

A further example of the action of ammonium salts in alkaline solution is seen in the reprecipitation of aluminium hydrate from an alkaline solution of potassium or sodium aluminate.

The use of 140 grms. of ammonium chloride in the litre of magnesia mixture not only assists the rapid precipitation of ammonium-magnesium phosphate, but also prevents the possible precipitation of magnesium hydrate, which sometimes occurs when the whole quantity (70 grms. per litre) is employed.

I trust that these few examples which I have brought before you may be the means of showing the advantages that are to be obtained in the laboratory by the use of flocculating or coagulating agents.

SESSION 1897-98.

*Meeting held on Tuesday, October 26th, 1897.*

### CHAIRMAN'S ADDRESS.

THE Scottish Section of the Society was formed at a meeting held in Glasgow on the 5th of January 1884; it has, therefore, nearly completed its fourteenth year. After an infancy and childhood of exceptional vigour and promise, it is now about to pass into the periods of youth and manhood, and I trust that my successor in this Chair, 14 years hence, will have the satisfaction of recording an equally successful passage through these later periods.

It was largely due to the wisdom and foresight of the founders of the Section 14 years ago, that these early periods were passed through so safely and successfully, and that the Section is in such a position to-day that we can look backwards with pride and satisfaction, and forwards with confidence and hope. But if we are in this privileged position through the wisdom and loyalty of the founders of the Section, it behoves us to remember our own duties and responsibilities in order that we may put forth our best efforts to provide for the growth and development of the Section through the coming years.

In setting ourselves to enquire how we may best forward the interests of the Society of Chemical Industry, it is not amiss that we should try to arrive at a clear idea of what are the actual and what the possible functions of the Society. In the Byelaws the objects for which the Society was established were stated to be:—

- To advance applied chemistry in all its branches.
- To promote the acquisition and practice of that species of knowledge which constitutes the profession of a chemical engineer.
- To enable all persons interested in applied chemistry to meet and to correspond, to facilitate the interchange of ideas respecting improvements in the various branches of chemical manufacture, and to publish and communicate information on such subjects.

The first of these declared objects is sufficiently wide to contain the two which follow, which may be taken as suggestions more in detail as to how the "Advancement of Applied Chemistry" was to be secured. The wording of *b.* (the second object) suggests that it was at first intended that the Society should interest itself directly in the education and certification of Chemical Engineers, to do in fact for that profession what the Institute of Chemistry has done for professional chemists, or the Institute of Civil Engineers has done for the members of that profession. So far as I know, nothing was ever seriously attempted in this direction. The times were certainly not ripe for any such attempt when the Society was founded, and it is very doubtful if it is now so constituted that it could move in this direction without sacrificing much of the broad catholicity in its membership which I venture to think is one of its very best characteristics. It ought immensely to strengthen the claims of the Society to the respect and

consideration of all public and official bodies, that it is in no sense a close professional or trade corporation, but that it exists solely for the benefit of all of the industries in which chemistry is concerned, and for the benefit, therefore, of the very large proportion of our population who are connected with these industries, either as capitalists, organisers, or wage-earners. It is only necessary to glance through the lists of presidents, members of council, and of local committees past and present, to realise how widely representative the Society is, and to feel assured that it would be next to impossible to use it for any narrow or selfish professional or trade objects.

The Society, having from the outset abandoned this idea of taking upon itself educational and diploma-granting functions, has to a large extent refrained from exercising any directing influence over the technical education movement of the past decade. At the present moment, when public attention is being so generally directed to the question of the commercial competition of other nations, and the important bearing on it of technical education, I believe there is no single body or corporation which has so much right to speak with authority on the subject as the Society of Chemical Industry with its 3,000 members, drawn from every branch of chemical industry, as well as from all of the leading universities, colleges, and laboratories. And yet we are compelled to confess that the Society as such has never made any adequate deliverance on this great subject, nor has the council in its representative capacity ever been consulted by the Government or by municipal authorities upon educational subjects. Surely there is here a noble opportunity for the Society to fulfil one of the express objects with which it was founded. The wise and thoughtful utterances of the past presidents and chairmen of Sections, show how much latent strength there is within the Society to deal with this subject if the collective wisdom and energy were judiciously led into definite channels.

There is ground for much satisfaction in the conspicuous success which has attended the attainment of the other objects set forth in the Byelaws. Those of us who have regularly attended the meetings, general and sectional, and who possess the 15 volumes of the Journal, which form so noble a record of work done, cannot fail to realise the splendid impulse which has been given to the more scientific study of the chemical industries, as well as the lasting benefits which have followed to the members themselves through the freer intercourse which the Society set itself to establish.

The "Advancement of Applied Chemistry in all its Branches" appears to include the proper collective representation of chemical industry in its relations to the legislature and to the executive government, Imperial or local. It is evident that the Council has kept this function of the Society before it, and in London, at least, slow, but certain progress is being made towards the attainment of official recognition. In the provinces, on the other hand, little or nothing has been accomplished in this direction, partly, no doubt, because the Sections have never set themselves seriously to work to obtain such recognition. It would be gratifying to us all if it were to become a natural and ordinary thing for the Lord Provost, and corporation of a city like Glasgow, to invite the Society to organise a discussion on any matter of public interest before taking any important steps in dealing with questions of industry or health, in which applied chemistry or physics take a prominent place. I do not, for a moment, mean to suggest that the Society should in such cases take the place of the paid professional adviser; but it is certain that there are many large questions which might be profitably discussed before they reached the stage at which they could be judiciously placed in the hands of the professional expert. In such cases a free discussion by men trained for the study of technical problems would certainly help to clear the way for final settlement.

To take another example, how gladly we should have received and complied with a request from the recent Petroleum Committee that the Society as a whole should discuss the great question of safe and unsafe oils, and should then present to the Committee a carefully prepared report embodying the results of these discussions in which both sides should be fairly and clearly stated and argued.

With such a report before it the Committee would have been in the position of the Lords of the Appeal Court, who do not themselves hear evidence, but have the evidence and arguments brought before them in a clear concentrated form, and with the personal element practically eliminated.

We want the public to realise that the members of this Society have enough public spirit to be willing to devote some of their skill and experience to the service of the community. Such service is accepted quite naturally, if a man proposes to represent a constituency in Parliament or on the Town Council. We do not propose to sacrifice so much of our time as either the member of Parliament or the Town Councillor; but we are sincere in our offer of service and we think it will have a value.

Your Committee feel that the time has come when it will be advantageous to introduce certain changes in the arrangement of the meetings for the Session. Hitherto it has been the custom for the Section to meet monthly during the Session, either in Edinburgh or Glasgow. At these meetings a large number of interesting and valuable papers have been read; but only occasionally has it been possible to deal at all exhaustively with the subjects discussed, as it has seldom been possible to secure a full attendance of members sufficiently interested in the special branch of industry dealt with. There are many reasons for this, some of the members live out of town, and for those who live in town the pressure of evening engagements is such that meetings like ours are apt to give place to others of a more attractive kind.

For the forthcoming Session it is proposed to hold some of the meetings at centres of special industry, and to devote the whole afternoon or evening to the reading of papers and the discussion of matters likely to be of interest to manufacturers and their employees. If this scheme can be efficiently carried out it is believed that benefits both direct and indirect will accrue. I believe that a great deal too much has been made of the supposed unwillingness of manufacturers to take part in such discussions, or to allow their employees to do so in case they may be expected to disclose the special secrets or the dearly bought experience of their manufacture. As a manufacturer who has had considerable experience in working new processes, both patented and unpatented, I have, as might be expected, the utmost sympathy with the right and natural desire to conserve the results of brains and experience for the primary use of their possessors, but I can personally testify to the great help which my own work has received from the stimulus of meeting workers in departments other than my own, as well as from the unique stores of information contained in the Journal. Having been the recipient of these benefits it has appeared to me a duty to try from time to time to give something of my own work and experience, on the chance that it might perhaps be helpful to some other member. To those who feel that any connection of themselves or their employees with the Society might endanger their special trade secrets, I should like to say that the Society does not want yours or any man's secrets, but it does urgently want you to join in the intelligent discussion of the scientific principles which underlie each and every manufacture, and it can promise you that if you give to the common fund some of your wisdom and experience you will receive in return the powerful stimulus of criticism, which may lead you to do your own work better. And further, that by contact with the active minds in other branches of industry your own mental horizon will be widened, and you may find that principles which have been worked out in some widely different branch of industry have a valuable application to your own special work.

It is one of the most important functions of the Society to aid in opening up cross tracks between the various departments of chemical industry. Some manufacture may be languishing for want of a new raw material, another may be at a standstill for want of some special kind of plant, which, all unknown to the manufacturer, is perhaps in regular use in another department of industry. The Society ought to be the instrument for bringing these interests into touch.

What the Committee most desire is, that the manufacturers and employees connected with special industries

should be willing to utilise the Society by bringing up at its meetings or by correspondence, problems and difficulties which may be limiting or injuring their industry. These difficulties need not necessarily be of a purely technical or chemical kind, they may be legislative or fiscal, or commercial. As I reminded you a little while ago, the first and chief object of the Society is "To Advance Applied Chemistry in all its Branches." Surely that is wide enough to cover every possible case that we may have to deal with.

There is a feeling in the Committee that something should be done to give the meetings more of a social character so that the members may have some opportunity for conversation. This would have many advantages, not the least of which would be, that the older members might take the opportunity of becoming acquainted with the younger men who have still their position to make. This would be good for both classes. The young men are on the outlook for new spheres of usefulness, and it is to the older men they must look to provide them with these. The older men want young hands and active brains to help them, and it ought to be worth their while to keep in touch with the coming men. If the new scheme for holding meetings at various places in the country is found to be workable, one of its advantages will be that the meetings will necessarily be much more social.

In connection with this proposed new departure allow me to illustrate my meaning by a reference to a trade with which you are all more or less familiar, I refer to the shale oil industry.

The history of this trade for nearly 20 years has been one long struggle against the results of excessive competition from abroad. No sooner has an improved yield or a reduced cost been evolved to meet a decline in selling price, than the trade has been faced by a further decline, and the hoped-for margin of profit has again disappeared. No one who knows the history of the industry can doubt that a splendid battle has been fought against very heavy odds. But the very fact of the great technical strength within the industry has perhaps kept it from gaining all the advantage which might have been derived from the resources of some other branches of industry, either through the adoption of entirely new processes or apparatus, or through the finding of new outlets for the products of the industry. The time appears to have arrived when, by a full presentation of the circumstances of the industry, such as can be made through the Society's meetings and Journal, opportunity may be given for some entirely new departure which may save a most important industry from the danger of extinction. In view of the great importance of the oil industry in Scotland, the Committee of the Section have arranged to hold the second meeting of the Session at Broxburn, when various subjects will be presented for discussion. In order to clear the way for a discussion of the special points which are to be brought before that meeting, it appeared desirable that a portion of the address at this opening meeting should be devoted to a general survey of the technical and commercial position of the shale industry. It is hoped that this general sketch may be the means of arousing such an interest in the industry as will ensure the presence and help at the Broxburn meeting of members, whose talents and abilities have not yet been directed to the problems of the shale industry. It is further hoped that the Broxburn meeting may be the means of introducing to the notice of technologists who are not familiar with them, the wide range of products which are so plentifully and cheaply produced in this industry.

During the past 14 years, papers dealing with various features of shale oil manufacture have from time to time been read before the Section, and printed in the Society's Journal, and in his opening address in 1894 Mr. Robert Irvine described certain new developments in connection with the visit of the Society to Broxburn Works, but no attempt has been made to give any general resumé of the progress all along the line in this interesting industry. It is quite natural that papers dealing with special inventions or details should treat of their subjects at so close a range that the resulting pictures are more or less "out of scale" when viewed in connection with the larger interests of which they only

form a part, so that it would seem as if an occasional corrective ought to be applied in the shape of a general survey of the whole subject from a broader point of view. On more than one occasion I have advocated the cultivation of such general surveys; but that it is one thing to preach and quite another thing to practice, I soon found out while preparing the following sketch, for the subject grew larger and larger while the time for preparation grew shorter; I feel impelled therefore to ask your indulgence in so far as my sketch has fallen short even of my own ideal.

### THIRTY YEARS OF PROGRESS IN THE SHALE OIL INDUSTRY.

BY G. GROF BELLEY.

THE consideration of this subject naturally begins with its raw material, the shale, but as the shales of Mid and West Lothian have been fully described by Mr Robert T. Moore, C.E., in a paper read before the Federated Institution of Mining Engineers in 1892, it is only necessary for our present purpose to refer to this part of the subject in very general terms. These shales occur below the coal measures, and taking them in their order from above downwards they are known as Fells, the Broxburn, the Dunnet, the Barracks, and the Pumpherston seams. Broadly speaking the working of these seams in point of time has followed the same order. The Addiewell Works were put up over 30 years ago to distil the Fells seam, Uphall, Oakbank, and Dalmeny followed up with the Broxburn seams. Ten years later the Broxburn Works came in with its splendid field of the same seams, and five years later the Pumpherston and Holmes Works took up the Pumpherston shales. The Dunnet and Barracks seams came into general use at about the same time as the Pumpherston. Fells seams yielded about 35 galls. of crude oil per ton, Broxburn seams about 32 galls., Dunnet seams about 25 galls., and Pumpherston about 20 galls. The lower seams, as a rule, yield a larger percentage of paraffin wax, and more ammonia than those above them, and, occurring as they do in thicker beds, they can be worked more cheaply, so that the difference in oil yield does not correctly represent the difference in their value. Thirty years ago the chief supplies were drawn from the Fells and Broxburn seams, while to-day the Pumpherston and Dunnet are at least equally important sources. These changes in the character of the shales worked during the past 30 years are so important that they must not be lost sight of in what follows:—

#### RETORTING OR DISTILLING THE SHALE.

When I joined the Oakbank Oil Company in 1869 a fierce controversy raged between the respective upholders of "Vertical and Horizontal Retorts," and I well remember my initiation into the mysteries of the subject by my early instructor, Mr. John Galletly, who, as chemist to Mr. James Young, founder of the industry, had acquired an immense fund of experience both valuable and unique.

The vertical retort was a cast-iron tube of oval or circular cross section, built vertically in an oven of brick work. At the top of the tube was fixed a charging hopper closed by a bell valve, while the bottom end dipped a few inches under water, contained in a shallow iron tray or pan. Every hour or so a small quantity of "spent shale" was raked out from the bottom through the water in the tray which served the double purpose of closing the retort and quenching the "spent shale." After every draw a corresponding quantity of fresh shale was introduced through the bell valve in the hopper so that the heated portion of the retort was kept filled with shale. The volatile products were removed by an exit pipe at the upper part of the retort. Fig. 1 shows this retort in vertical cross section.

The horizontal retort was a tube of cast iron of oval rectangular or D cross section closed at one end by an iron door and provided at the other end with an exit pipe through which the vapours and gases were led to condensers. These tubes were set horizontally in brick ovens heated by coal fires, in some cases the setting was similar to that of the ordinary gas retorts; but Fig. 2 shows a form of setting which was commonly used at the period

referred to. They were usually filled with shale through the end door like gas retorts, but sometimes a charging hopper was provided on the top side of the retort; after

Fig. 1.

SECTION

PLAN

OLD VERTICAL RETORT.

In Oakbank Works, in 1869, the retort plant consisted of one bench of horizontal retorts and several benches of small vertical retorts of circular cross section. As these different retorts were worked side by side for several years, we had ample opportunity to test the one against the other. From shale of the Broxburn seam the horizontal bench yielded 24—25 galls. per ton of shale of a light clean crude oil, while the vertical benches yielded 32—33 galls. of a heavier and a darker oil, which lost more on refining than the horizontal oil, but yielded a larger percentage of paraffin wax, then, as now, the most valuable constituent of the crude oil. This, together with a larger yield of ammonia, turned the scale in favour of the vertical retort, and Oakbank became committed to that form.

The proper principles for setting and firing retorts had not yet been arrived at, and the waste of coals and of retorts was prodigious. The furnaces were relatively enormous, while the ovens in which the retorts stood were narrow and confined. The flame and hot gases from these powerful furnaces were led directly round the lower parts of the retorts, but to protect them from the keen action of the flame these parts were surrounded with fireclay covers moulded to the shape of the retorts. Coals were shovelled into the fires often at the rate of 6 cwt. for every ton of shale distilled, the combustion requiring a powerful chimney draught, which dragged large quantities of the powdery ash of the coal into the narrow channels surrounding the retorts, rapidly closing them as well as adhering to the hot surface of the retorts and forming a non-conducting coating to overcome, which involved more

being filled with shale the doors were luted with fireclay and screwed up tightly. The volatile products were driven off in from 16 to 24 hours, after which the "spent shale" was removed by the end door and a fresh charge was introduced. These horizontal retorts were called intermittent, and the vertical retorts continuous working. Steam was regularly introduced into the lower end of the vertical retorts to help to sweep the oil vapours upwards to the exit pipe, but was seldom or never used in horizontal retorts. A great variety of both forms were to be found at work in the year 1869, each form had its partisans who believed that the true wisdom was only to be found in their particular retort benches.

In Oakbank Works,

in 1869, the retort plant

Fig. 2.

PLAN

OLD HORIZONTAL RETORT.

and more vigorous firing. Naturally the life of the retorts themselves was short, they generally bulged a little below the centre, and became hopelessly burned and cracked, sometimes even in 6, 9, or 12 months, especially if, at any time, the fireman had the run of a better class of coal than they had been accustomed to.

The crude oil, costing 1d. or more per gallon, suffered a loss of 40 per cent. on refining, and only contained about 7 per cent. of paraffin scale; an oil which to-day would be considered by any refiner too dear at a 1d. per gallon.

It was just at this time (1868-69) that Mr. William Young was busy re-discovering the virtues for paraffin making of that "low-red heat" which nearly 20 years before Mr. James Young had laid down as the proper temperature for the distillation of shale, but which the shale distiller had never been able to attain to practically. Mr. Young's 1868 retort, Fig. 3, was the outcome of these labours, and those of us who first saw and analysed the

wonderful product of that gently-applied low-red heat, felt instinctively that a new era had dawned upon the shale distilling industry. But alas, for the complexity of the technical mind, instead of grasping the simple fact that the new retort was so excellent, mainly because the genuine low-red heat had at last been applied to the shale, thanks to the admirable setting and firing of the retort, we all wandered off into theories of "downward" and "upward" distillation, and a new controversy broke out which bid fair to be as prolonged and bitter as the horizontal *versus* vertical had been!

A bench of these retorts was erected at Oakbank in 1871, and continued to work for many years, producing an oil

of fine quality; but a closer acquaintance with its practical working showed that the double casing, while adding considerably to the first cost, was also a source of weakness owing to the formation of carbon deposits between the outer and inner shells which prevented the free passage of heat to the shale and added to the consumption of fuel.

A few years previously, Macbeth had erected retorts in which the combustion of the shale in the lower parts supplied heat for the distillation in the upper parts of the retorts. This retort never advanced beyond the experimental stage.

Meantime, Mr. William Young was feeling round after a further advance in the same direction, by which the residual carbon of the "spent shale" was to supply the necessary fuel for the distillation. In 1872, the new retort, Fig. 4, was brought out (Eng. Pat. 2487, 1872), and we were fain to admire the ingenuity with which Mr. Young's "gas lute" separated the distilling zone of the retort from the fire chamber below, into which the spent shale passed for combustion. But this was too delicate an instrument to place in the hands of the unskilled labourers who

work retorts. With skilled supervision it would do all that its inventor claimed for it; but unfortunately with benches containing hundreds of retorts the unskilled labourer had to be reckoned with, and often entailed much wreckage and misfortune before he became even moderately skilful in handling the retorts.

But Mr. Young had now shown us that the requisite uniform "low-red" heat could be obtained by the combustion of the residual carbon of the "spent shale" and that this heat could be perfectly well applied to the shale without the intervention of the costly double-casing of the 1867 retort.

The finishing touch was applied by Mr. N. M. Henderson in 1873 when, through his beautifully designed arrangement of retort and furnace chamber, the carbon of the spent shale was made available for supplying exactly the kind of heating required without making too many demands on the skill and attention of the labourer. This retort has been so often described (this Journal, 1889, 1909), that it is only necessary to direct your attention to its general construction as shown in Fig. 5. (Eng. Pat. 1327, 1873.)

HENDERSON'S RETORT, 1873.

The first benches of Henderson's retort were erected in Oakbank Works in 1874, and these identical retorts continued to work without change or renewal for 12 years till 1886, when they were pulled down, not because they were worn out, but because the times had changed.

When the Broxburn Oil Company began its operations in 1878, Henderson's retorts alone were erected, and there can be no doubt that the brilliant success of that Company during its earlier years was largely due to their excellent qualities and perfect suitability to the shale of the Broxburn seam. Hitherto, retorts had been a perpetual source of weakness, and in the older works a large staff of bricklayers and fitters were continually at work repairing and renewing the retort benches, pulling down the worn out and rebuilding the new. Now, at last, it was felt that a kind of finality had been reached, and that the fortunate

manager who possessed these retorts would be able to leave them in charge of his subordinates, and devote his skill and energy to perfecting the other apparatus of the oil work.

The directors of the Oakbank Oil Company had not seen their way to pull down the vertical retorts and replace them by Henderson, so in 1878 we set to work to apply the best knowledge of the time to improve the conditions of the shale distillation in the vertical retorts. Mr. William Young's results had shown plainly that the moderate equal heating was best obtained by setting the retorts in large ovens, with as much free space round each retort as possible, these ovens being heated by furnaces burning under a very moderate draught. We therefore cleared the old settings of all superfluous flues and brickwork, reduced the size of the furnaces, and gave every inch of available space to the ovens in which the retorts stood. By reducing the amount of brickwork with which the retorts had been covered up, the available heating surface was considerably increased, so that, although the working temperature of the metal of the retorts was reduced to a very dull red, barely visible in daylight, the same through-put of shale was maintained, without any diminution in the yield of crude oil. The effect of this alteration on the quality of the crude oil obtained was very marked. Instead of the dark brown low-yielding oil of the old setting, we obtained a clean bright green oil, which contained 10 to 11 per cent. of paraffin scale, an improvement of fully 2 per cent., and valued at, at least, 20*d.* per ton of shale. The other products were improved in proportion. The coal consumption was reduced from 5 cwt. per ton of shale to  $1\frac{1}{2}$  cwt., while the cost for repairs and renewals fell to a fraction of the former amount. Fig. 6 shows one of these improved

Fig. 6.

OAKBANK VERTICAL RETORT, 1880.

settings in vertical cross section. Retorts of this form, which were rebuilt in 1878, were practically as good as ever when they were pulled down in 1886. The chief drawback in these improved vertical retorts was that the yield of sulphate of ammonia was reduced from 15 lb. to about 12 lb., a loss in value equal to about 4½*d.* per ton of shale.

In the matter of yields and value of the products the Henderson retort had little, if any, advantage over the

improved vertical, but in cost of working the advantage was quite decided. While the vertical retort was worked by the method of hourly withdrawals of a small portion of the charge, which was replaced by introducing a corresponding quantity of fresh shale through the hopper at the top, the Henderson was completely emptied and filled every 17 or 18 hours, and was practically left to itself for the whole of the intervening time. It is obvious that such a method of working can be carried out with fewer labourers and at a correspondingly lower cost. The firing by means of the carbon of the "spent shale" resulted in saving a portion of the coal used by the vertical retort.

Between 1878 and 1880 Mr. McCutcheon at Addiewell, and Mr. Jones at Dalmeny, as well as other users of vertical retorts, also improved their settings so that the very low grade oil of the earlier years had become a thing of the past. Various attempts were made at Oakbank still further to improve the vertical retort. The diameter of the retort was increased, and a greater number of retorts were fired by a single fire, but the net result showed no improvement on those first erected.

Taking stock now of the position of retorting during the period 1878-83, we find that at Broxburn, Burntisland, and Linlithgow the Henderson retort was used exclusively, while at Addiewell and Uphall it had partially taken the place of the vertical retort. At Addiewell, Dalmeny, Oakbank, and Uphall there were still a number of more or less "improved" vertical retorts in use.

In 1880 the comparatively low yield of ammonia obtained from the improved vertical retort forced us to reconsider the whole subject of the ratio of the total nitrogen in the shale to the ammonia obtained, which I had first worked out in the years 1871-73. This matter was laid so fully before the Section in 1884 (this Journal, 1884, 216), that it will only be referred to now so far as is necessary to complete this historical sketch.

The leading idea of the new system which was simultaneously patented by Mr. W. Young and myself in 1881 was to subject the "spent shale" of the oil-making retort

Fig. 7.

BAILEY'S RETORT, 1881.

to a further treatment with steam at a higher temperature than that suitable for oil-making, with the object of converting the residual nitrogen of the shale into ammonia.

The first retort for carrying out this double process was erected at Oakbank early in 1881. The drawing, Fig. 7, shows this retort in vertical cross section. It was intended to supply the answer to two vitally important questions, (1) was it possible economically to win an increased yield of ammonia by the application to the spent shale of a higher temperature? and (2) what influence would this supplementary treatment of the shale have upon the primary process of paraffin oil distillation which was to take place in the upper part of the apparatus?

The latter question had for us at that time a peculiar significance as we had only emerged from the "old vertical" period, and our recently acquired horror of high temperatures and local heating made us specially fearful as to the results to be expected from a retort which looked like the old vertical at its very worst. Fortunately these fears were groundless, and I shall not easily forget the delight with which we first saw a clean looking, bright green crude oil running from the condensers of the new retort, and when an assay of the oil showed that it contained to the full as much paraffin wax as the best existing crude oils while the liquor tank contained all the extra ammonia we had hoped to secure, we felt that our new system was to be the salvation of the trade! That the new system has indeed proved the salvation of the trade I suppose there can now be no doubt, but alas for the pleasant feeling of finality which we had begun to associate with the Henderson retort and its simple, almost automatic, distillation of our shale, it seemed as if we had again to begin the whole matter of retort construction afresh with certain new and formidable difficulties thrown in. I had taken years to arrive at the regulation of one satisfactory temperature for distillation, now we require to provide for two, and one of them much higher than anything we had had to deal with before. And this high temperature not only affected the retort itself but it also attacked and fused the shale ash which had been denuded of its carbon by the action of the steam. It is evident that the fusion of even a very small portion of shale occurring near the bottom of a long comparatively narrow tube could interfere most disastrously with the regularity of working and results.

The first benches of retorts under the new system were erected at Oakbank during the summer of 1881, and justified their existence by producing a doubled yield of ammonia along with an increased yield of paraffin shale. With careful supervision the working was quite regular and satisfactory, but so many points required to be watched especially during the education of the retortmen and the results of neglect or carelessness were so serious that this retort was not the final expression of the new system.

Meantime Mr. W. Young, after some preliminary trials, proceeded with the erection of some benches of retorts at Pentland Works of the form which has since become so well known as the Pentland or Young and Beilby retort. The drawing, Fig. 8, shows these retorts in vertical cross section. While still liable to the dangers and disadvantages which result from the employment of so wide a range of temperatures within the same apparatus, these were minimised by the larger size of the individual retorts by the easily accessible curved mouthpiece and door and by the use of a gas generator instead of an open fire. Large numbers of these retorts have been in constant and successful use since 1884 and it is an interesting fact that those benches of retorts which have been least altered or interfered with have continued to work most satisfactorily.

The monthly statement of the Scottish Mineral Oil Association for last April showed that the retorts in use in Scotland consisted of: Henderson, 826; Young and Beilby, 3,636; other kinds, 336.

No sooner were the general principles of this new system and its results published than numerous inventors set to work to improve upon the idea. It would be quite impossible, even if it were desirable, to detail all of these attempts, many of which were never carried out on a practical scale at all, but considerable interest attaches to a few of them.

Early in the course of our experiments, Mr. Young and I had tried the effect of mixing a proportion of air with the steam applied at the lower end of the retorts, with the object of burning a portion of the fixed carbon, so as to supply a part of the heat necessary to enable the remainder

Fig. 8.

YOUNG AND BEILBY'S IRON AND BRICK RETORT.

of the carbon to decompose part of the steam, and to set free the fixed nitrogen as ammonia. The plan worked quite successfully so far, that is to say, the carbon of the "spent shale" was nearly all burned away, and a good yield of ammonia was obtained, although a lower heat was applied to the outside of the fireclay retort. As every volume of oxygen in the air took in with it four volumes of nitrogen, the quantity of air that could be economically employed was very small. Up to a certain point the extra volume of gas passing up through the red-hot spent shale acted usefully in carrying with it heat that was available for effecting the primary distillation of the oil from the shale in the upper part of the retort. It also helped to carry off, more rapidly, the oil vapours as they were formed, thus reducing the amount of secondary decomposition to which these vapours were subjected. But beyond this point the presence of the nitrogen was harmful, not beneficial. The volume of gas from a ton of shale had already been increased by the new system from 2,500 up to about 14,000 cu. ft. This increase had already rendered the condensation and scrubbing of the more volatile parts of the crude oil a matter of considerable difficulty, so that a further addition to the volume of gas through the admission of atmospheric nitrogen increased these difficulties, and was looked upon as not economical. Further, the addition of a quantity of inert nitrogen to the gas rendered it much less valuable as a fuel.

In 1884-85 an attempt was made, by means of what was known as the "Couper Rae retort," to effect the separation of the ammonia in the lower retort entirely by the agency of internal heat generated by a free mixture of atmospheric air with the steam introduced. These retorts shown in

Fig. 9, were built below as solid-walled combustion chambers entirely without flues or means of external

Fig. 9.

COUPER AND RAE'S RETORT, 1883.

heating. After a considerable amount of time and money had been spent in trying to get satisfactory results from them, these retorts were finally abandoned.

Later on, Messrs. A. Neilson and A. C. Thomson renewed the attempt to work with air combustion in the lower part of a retort of considerable size, built like a blast furnace; but I understand that the method was only successful with shales containing a large percentage of fixed carbon.

When it was found, in the case of the Pentland retorts, that the joint between the iron above and the firebrick below was troublesome and apt to leak, a number of benches were built (Fig. 10) in which the iron retorts were replaced by firebrick, that is to say, the firebrick retort was carried right up to the hopper, thus removing the principal joint between the iron and fireclay into a cooler region. These worked well until the pores of the bricks and the joints between them became loaded with carbon deposited by the oil, when the walls of the retorts swelled and cracked, becoming leaky at the joints.

In 1885 the Hermand Oil Company erected a bench of retorts at their Breich Works under licence from us. These, as shown in Fig. 11, were longer than the Pentland retorts, and differed from them further, in as far as each retort was provided with a separate hopper. They worked for several years and gave excellent results, the increased height being evidently an advantage, as it enabled the shale to be subjected to heat for a longer time. Subsequently the same Company erected several benches of retorts at the Hermand Works, in which the brickwork was carried up to the hoppers as in the Pentland retorts, already shown (Fig. 12). While these retorts began well, they soon became leaky and turned out inferior oil, thus confirming the experience which had been gained with the Pentland retorts.

All of the retorts referred to have been carefully drawn to scale, so as to show them in their true relative size.

The experience of the past 16 years with the Young and Beilby system of distillation has shown that the original combination of iron and fireclay retorts is a practical

Fig. 10.

PENTLAND RETORT, 1882.

Fig. 11.

BREICH RETORT.

necessity, and that with proper care in its design and construction the combined retort can be maintained in good working order for years. It has also shown that the maintenance of regular heats on the upper and lower retorts is very difficult, except with a purely gaseous fuel, generated by the retorts themselves when the shale is suitable—otherwise by independent generators.

Fig. 12.

SECTION

PLAN

HERMANN RETORT, 1889.

The fluxing and clinkering of the shale ash is still the most serious difficulty in practical working, and during the past few years Mr. N. M. Henderson, Mr. Crichton, Messrs. Bryson, Fraser, and Jones, as well as some others, have designed and erected retorts in which the curved shoot of the Pentland retort is removed and replaced by various pieces of mechanism for the continuous withdrawal of the spent shale ash. It is undesirable that I should in any way anticipate what these gentlemen may have to tell us about their several inventions at the Broxburn meeting next month; we shall therefore leave the subject of retorting at this point.

#### SULPHATE OF AMMONIA MANUFACTURE.

Thirty years ago the method of dealing with the ammoniacal liquor from the retorts was crude in the extreme. The liquor was boiled off in ordinary egg-codded steam boilers, a very large proportion of the water having to be evaporated in order to exhaust the ammonia even moderately well. In working with a single boiler it was usual to feed slowly till the liquor was well up the glass, and then to shut off the feed and boil off till the liquor was down near the bottom of the glass. At this stage a portion of the spent liquor was blown off and the feeding started again. When several boilers were worked in series, the spent liquor was fed into the first of the series and the fresh liquor was blown off from the last.

The shale liquor was very weak as compared with gas liquor, containing from 0.5 to 0.7 per cent. of ammonia, only a small proportion of which was present as fixed ammonia, so that lime was never used.

The general result of this system was far from satisfactory, the exhaustion of the liquor being, as a rule, very imperfect. It was not at all unusual for the spent-liquor still to contain a fifth of the whole ammonia.

Up till 1881 there was an impression that the Coffey still was not applicable to the liquor of the oil works; either the liquor was too dirty or too weak, or the quantity was too small to be economically dealt with by the large type of Coffey stills which had been designed for the spirit industry.

At Oakbank, in 1881, a series of experiments was carried out on the use of open steam in column stills, with the result that a simple form of still was designed and brought into practical use during that year. This column still is shown in section in Fig. 13. It was cheaply constructed, easily worked, and kept itself clean even when the liquor contained oil sludge. It dealt economically and effectively with even moderate quantities of liquor. This still seemed to meet the requirements of the time, for it was quickly adopted by a number of the oil companies.

Since that time the use of column stills has become so common in gas works that almost every maker of gas plant has his own pattern. Several of these designs are much more suitable for dealing with large quantities of liquor than the more simple form, whose interest is now chiefly historical.

The introduction of the column still effected a very great saving in fuel, while it reduced the loss of free ammonia in the spent liquor to a mere trifle.

The requirements of the Alkali BEILBY'S AMMONIA ACTS drew a good deal of attention to the "cracker boxes," in which the ammonia gas is converted into sulphate, and the necessity for working with close gas-tight boxes resulted in various improvements in their construction and working, which further cheapened the cost of producing sulphate.

This cost, which 30 years ago was sometimes as much as 6*l.* to 7*l.* per ton, has been reduced now to under 3*l.*

An important economy, first proposed by Mr. W. Young in 1880, was the returning of the waste steam from the cracker boxes into the retorts in place of a corresponding quantity of fresh steam. The practice has since become universal; the whole of the exhaust steam from engines and pumps, as well as from the cracker boxes, is taken into a common system of piping and led to the retorts, so that very little fresh steam is used. The saving thus effected cannot be less than 4*l.* per ton of shale.

Fig. 13.

#### REFINING OF THE CRUDE OIL.

In the chemistry of oil refining there has been practically no change for the past 30 years. Oil of vitriol is still used for the removal of basic tars and resinous bodies, and caustic soda solution for the removal of the cresote tars and sulphur compounds. The different oils are separated by fractional distillation, and the paraffin by cooling, crystallisation, and filtration. While these general principles remain the same, the details of their application have been altered in the direction of increased precision and economy. Fuel, labour, and chemicals are all used more sparingly and with better effect. In one respect the refining of 1869 to 1876 was very imperfect; that was in the making of lubricating oils. Burning oils and paraffin wax of the finest quality were made in the works of Young's Paraffin Light Company more than 30 years ago, but the lubricating oils of 20 to 25 years ago left much to be desired. Neither in colour, in setting point nor in

viscosity were they at all up to the standards which have come into force since 1877.

The colour difficulty was overcome by distilling the heavy oils off caustic soda, the viscosity was raised by the plentiful use of superheated steam in the distillation, and the setting point was lowered by improved freezing machines and filter presses.

A great step forward was made when Mr. N. M. Henderson perfected his apparatus for the continuous distillation of the oils. This apparatus was fully described in 1889 by Mr. D. B. Steuart (this Journal, 1889, 100) in a paper read before this Section. The use of this system in Broxburn Works at once reduced the refining loss from 30 per cent. down to 26½ per cent., the quantity of chemicals used being also reduced. The entire cost of refining fell from over 1*d.* per gallon down to ¾*d.* or less.

The cooling of the heavy oils and the extraction of paraffin scale received a great deal of attention. As a rule each work had its own methods and apparatus for carrying out these operations.

An apparatus erected at Oakbank in 1885, and described in papers read before this Section in the same year (this Journal, 1885, 321 and 653) has continued to work satisfactorily, and has been considerably extended on the original lines.

In paraffin-wax refining the "sweating" process, which was brought out by Price's Patent Candle Company, has almost completely superseded the old naphtha process, greatly to the advantage of economy and safety. In this process the crude paraffin scale is melted and cast into cakes. These cakes are placed on drainers in ovens heated by steam pipes to a temperature just a little short of the melting point of the scale. The low-melting portions of the scale are sweated out of the cake, taking with them the oil and colouring matter, and leaving a small, but a purer and harder cake. One or two repetitions of this process are sufficient to bring the colour and hardness of the wax up to the required standards.

This process has been improved by Mr. W. M. Henderson (this Journal, 1894, 1043), so that the cost of handling the wax is greatly reduced.

The general effect of all of the improvements of the past 30 years has been to reduce the cost of refining a gallon of crude oil from 2·2*d.* down to 0·7*d.*, the latter figure including the refining of the scale into wax—an operation which was formerly carried out separately and at great expense.

#### COSTS AND PROFITS.

Thirty years ago market prices were still so high that it was not necessary to scan the works cost sheets very narrowly; indeed, many companies did not even trouble to make out cost sheets at all. It is, therefore, not possible to speak of the average costs of that time with the precision and certainty of to-day, when, in every works, costs are made out to the ¼*d.* of a penny.

#### COST OF SHALE.

I have not the experience which would justify me in speaking of the various factors which influence the cost of shale; in what follows, therefore, I simply take it as a fact that in 1868-69, as well as in 1897, shale of such a standard quality as the Broxburn 30-gallon seam could, in the more favourably situated fields, be mined and delivered to the retorts for 5*s.* per ton; and further, that the lower shades of the Dunnet Barracks and Pumphreston seams of 20-gallon quality could be worked for 1*s.* less, or say 4*s.* per ton. While passing thus lightly over the subject of shale costs, it is necessary to guard against any misapprehension as to the vital importance of the shale supply in determining the profitable working of an oil works. In the past history of the oil companies far more has turned on the quality and cost of their shale than has appeared on the surface; and for the future it is clear to those who know the trade best, that it is this question which will determine which companies shall survive in the struggle for existence. With these qualifications we may take it that the costs of 1868-69 were approximately:—

	Per Ton.
	<i>s.</i> <i>d.</i>
Shale .....	5 0
Retorting .....	5 0
Refining .....	5 6
A total cost of .....	15 6

The produce obtained from a ton of shale was:—

Burning oil .....	12·0 gals.
Lubricating oils .....	3·9 "
Paraffin scale .....	2·1 "
Sulphate of ammonia .....	12·0 lb.

The net prices of these products in the works were:—

	<i>d.</i>
Burning oil .....	15·0 per gal.
Lubricating oil .....	12·0 "
Paraffin scale .....	30·0 "
Sulphate of ammonia (cost of making being deducted) .....	¼ per lb.

Putting these figures into the form of a profit-and-loss statement we have:—

#### I.—YIELDS AND COSTS OF 1869, AT THE PRICES OF 1869 (BY OLD VERTICAL RETORTS), WITH A THIRTY-GALLON SHALE.

Costs per Ton.		
	<i>s.</i> <i>d.</i>	<i>d.</i>
Shale .....	5 0 =	60

Paraffin scale .....	2·1 " 30 =	63
Sulphate of ammonia, 12 lb. at ¼ =	9	299
Gross profit per ton of shale .....		112

Subject to deduction of commercial charges and interest.

The rapid development of the petroleum industry of the United States caused the price of burning oil to fall steadily from year to year, and by 1877 it had reached 9½*d.* per gallon, while lubricating oil was still in the region of 11*d.* to 1*s.* For these earlier years there was comparatively little lubricating oil or paraffin exported from America, but from 1877 onwards the exports went up rapidly. Five years later, in 1882, we find that burning oil had fallen to 4·3*d.*, lubricating to 7·5*d.*, and paraffin scale to 19·2*d.* per gallon, showing that the competition from America was telling now on all three products.

If we apply these prices to the costs and yields of 1869 we find:—

#### II.—YIELDS AND COSTS OF 1869, AT THE PRICES OF 1882 (BY OLD VERTICAL RETORTS), WITH A THIRTY-GALLON SHALE.

Costs per Ton.		
	<i>s.</i> <i>d.</i>	<i>d.</i>

Subject to addition of commercial and interest charges.

that instead of a profit of 9*s.* 4*d.* per ton there would have been a loss of 4*s.* 2*d.* But the improvements effected in retorting and refining had been sufficient to turn the scale on the right side; for the cost of retorting had been reduced

from 5s. 1d. to 2s. 6d. per ton, and the cost of refining from 5s. 6d. to 3s. 6d. per ton, making the total cost 11s., as compared with 15s. 7d. in 1869, while the yield of refined products obtained from 30 gallons of crude oil had been increased from 18 gallons up to 21·3.

### III.—YIELDS AND COSTS OF 1882, AT THE PRICES OF 1882 (BY HENDERSON'S RETORTS), WITH A THIRTY-GALLON SHALE.

#### Costs per Ton.

		<u>175</u>

Gross profit per ton of shale ..... 43

Subject to commercial charges and interest.

The profit-and-loss statement now shows a gross profit of 3s. 7d. per ton of shale.

In 1881-82 the introduction of the new system of retorting turned the attention of the trade to ammonia as a means of compensating for the falling price of oil products.

The price of sulphate of ammonia, which had been about 14l. per ton in 1869, had risen to 21l. in 1882, but the fall from this point was very rapid. The subjoined table, which was referred to by the Chief Inspector under the Alkali Acts in his report for 1896, shows the increase of production from 1882 to 1895 inclusive:—

Year.	Total Shale mined in the United Kingdom.	Total Sulphate of Ammonia recovered from the Shale.	Yield per Ton of Shale mined.	Price per Ton.
	Tons.	Tons.	Lb.	£ s.
1882	1,060,200	5,200	12	20 5
1883	1,167,300	6,400	12	16 10
1884	1,518,800	9,500	11	14 10
1885	1,770,400	16,200	20	11 15
1886	1,728,500	18,000	23	11 10
1887	1,411,000	21,100	..	12 5
1888	2,076,400	22,100	24	12 0
1889	2,014,000	24,000	26	12 5
1890	2,212,200	24,700	25	11 10
1891	2,361,100	26,900	25	11 0
1892	2,089,300	23,100	25	10 5
1893	1,956,500	28,500	32	12 10
1894	1,985,300	33,000	37	13 0
1895	2,212,000	38,300	39	11 0

Mr. Forbes Carpenter has pointed out that the quantity of shale in the second column does not exactly represent the quantity retorted, which on the average would be less than the quantity mined, as a certain quantity is used in gas-works. The fifth column shows average yearly prices of sulphate per ton.

In 1887 the prices for oil products had dropped to the lowest recorded point. Burning oil was 3·2d., lubricating oil 2·2d., and paraffin scale 16·8d. per gal., while sulphate of ammonia had come down to 12l. 5s. per ton.

In 1897 we find that prices had fallen to 3·41d. for burning oil, 3·19d. for lubricating, 14d. for paraffin, and 8l. per ton for sulphate of ammonia. The diagram (Fig. 14) shows the course of prices for 18 years.

The prices for ammonia are taken per pound, less cost of manufacture.

A profit-and-loss statement, with the costs and yields of 1882 at the prices of 1897, shows a loss of 2s. 3d. per ton of shale:—

### IV.—YIELDS AND COSTS OF 1882, AT THE PRICES OF 1897 (BY HENDERSON'S RETORTS), WITH A THIRTY-GALLON SHALE.

#### Costs per Ton.

	s. d.	d.

The sum of the balances from the tables (Nos. IV. and V.) is 4s. 3d., which represents the result of the improvements of the past 15 years, valued at the extremely low prices of 1897.

If we enlarge the period of comparison back to 1869, a statement of costs and yields of 1869, at the prices of 1897, shows a loss per ton of 8s. 6d.:—

Fig. 14.

Fig. 15.

This sum of the balance of Tables Nos. V. and VI. is 10s. 6d., which represents the result of the improvements of the past 28 years, valued at the low prices of 1897. If the shale through-put of Scotland is taken at 2,400,000 tons, we find that the value of these savings on one year is 1,260,000l. Unfortunately for the shareholders in the oil companies, the greater part of this handsome sum has not gone into their pockets, but has been left in the pockets of the consumers of the products!

The diagram (Fig. 15) shows graphically the progress of the costs, prices, and profits for the past 18 years of one of the leading oil companies.

A supplementary profit-and-loss statement is given, showing the results of working a 20-gallon shale, such as the Pumpherson, at the costs, yields, and prices of 1897:—

Subject to commercial and interest charges.

The most striking features disclosed by these later statements of profit and loss are, the extraordinary shrinkage in the value of the products from a ton of shale as well as in the costs for obtaining them. The significance of these shrinkages appears to be that nothing but an improvement of prices can raise profits to a satisfactory point. Costs have now been reduced to so low a point that there is small margin left for further reductions. I expect that we shall hear from Mr. Bryson next month something of what he has accomplished in the matter of retorting; but we cannot ignore the fact that each successive penny of reduction is more difficult to win than the last.

Like many others who have been interested in this industry, I have thought much and often on the possibilities which remain for developing new sources of profit. I shall conclude by referring to

MATTERS WHICH CALL FOR FURTHER INVESTIGATION.

(a) In the distillation of the shale itself an excessive proportion of the volatile constituents goes off as uncondensed gas. I use the word "excessive" advisedly, for I have found that small quantities of shale, when distilled at a very gentle heat in a moderate vacuum, yield a much larger proportion of oil and a correspondingly smaller proportion of uncondensed gas. I have had this fact before me for more than 25 years, but have never been able to see how it is to be made available practically.

(b) At the oil stills a similar waste takes place. Papers on the subject were read before this Section in 1887 by Mr. J. B. McArthur and myself, but I am not aware that anything has been done practically towards the utilisation of this gas.

The total production of this gas cannot be much short of 60 million cubic feet per annum.

(c) The basic tars, which are removed from the oils by the action of oil of vitriol, may have unexhausted possibilities. Every ton of shale produces from 3 to 4 gals. of these tars, so that from 7 to 10 million gallons are produced per annum.

The present practice is to wash and steam the free acid out of the tar, and then to burn it as fuel under the oil stills. Its value for this purpose cannot well exceed 15s. to 20s. per ton.

These tars contain a high percentage of nitrogen, and many attempts have been made to convert this nitrogen into cyanogen or into ammonia. Both conversions are possible; but it is doubtful if either of them can be commercially successful.

It is to a deeper and more exhaustive chemical investigation of the less volatile portions of these tars that attention ought to be directed.

(d) The resinous bodies which come off during the coking of the residue stills also deserve fuller investigation.

Chemically, the hydrocarbons which compose the oils and paraffins are not very hopeful subjects to tackle; but perhaps the oil chemists of the next generation may be able to feed us and to supply us with soap as readily as those of the present generation have illuminated and warmed us!

In order that the forthcoming meeting at Broxburn may be practical and useful, it is desirable that all who have questions to propose for discussion should communicate them to the Secretary as soon as possible. It is intended to devote a part of the meeting to the consideration of the latest departure in retorting—the use of automatic drawing appliances; but it will be most gratifying to the Committee of the Section if those who are most heavily interested in the future of the industry will make the fullest possible use of the occasion for the discussion of matters which may influence that future.

In conclusion I have to express my indebtedness to the managing directors and officials of the leading oil companies for the very great frankness and courtesy with which they have placed their records and experience at my disposal during the preparation of this sketch. This is a most encouraging experience for an official of the Society of Chemical Industry, and ought to reassure those of our friends who fear that the objects of the Society may be defeated through the unwillingness of manufacturers to co-operate with the Sections. It is for the Society to show its appreciation of this generous policy by doing all in its power in order that this important industry may gain, not lose, by the mutual intercourse and association.

Hon. Local Secretary:

Dr. H. Schweitzer, 77, William Street, New York, U.S.A.

SESSION 1897-98.

Meetings will be held on the third Friday after the first Monday in every month.

Meeting held at the College of Pharmacy on Friday, October 22nd, 1897.

MR. THOS. J. PARKER, VICE-CHAIRMAN, IN THE CHAIR.

THE SECRETARY read a letter from Dr. Chandler in which he expressed his regret that an imperative engagement out of town made it impossible for him to be at the meeting. He extended a hearty invitation to the members to hold their November meeting in the new Havemeyer Hall, in the Columbia University, in their new building on Morningside Heights.

DR. ENDEMANN said it became his sad duty to announce to the Section the death of their friend and co-member, Dr. Alsberg. Towards the end of August he commenced to

feel unwell, and decided to visit his family in the Adirondacks. Here he was suddenly taken worse, and though he rallied for a time, he died early in the following month.

Dr. Alsberg was born in 1812, in Waldeck, in Germany, and studied until about his fourteenth year at the Gymnasium at Korbach. After that, his father put him to business, but this was so much against his inclination that his father sent him to the Polytechnic at Brunswick, where he studied and graduated, obtaining a prize, which induced his uncle to furnish the funds for his university education. He first studied with Prof. Wochler; then later on with Prof. Geuther in Jena, and after graduating in 1861, became the University laboratory assistant. He then came to the United States with recommendations from Prof. Wochler to Prof. Joy at Columbia College, and Prof. Chandler engaged him as his private assistant, with whom he stayed about two years. He then commenced the manufacture of "Lactine," an infants' food, well known in Europe, but apparently unknown in the United States at that time. Not being well supplied with funds for advertising, he soon had to give up this manufacture. He then started the manufacture of vermilion, of which he was really the only successful manufacturer in the United States, and he continued in that business until his death. His business has been merged in various firms, the firm at the time of his death being Alsberg and Pfeiffer. He introduced thereafter almost every colour which is manufactured on a large scale. Though essentially a manufacturer, and as such intimately connected with trade, at the same time he never forgot science. Whatever he could do to help on the struggles of scientific men he did, and no doubt many of the members of the New York Section had been benefited by his friendship, and would sadly mourn the sudden recall of their friend from this world.

## THE CONSTITUTION OF HYDRAULIC CEMENTS.

By SPENCER B. NEWBERRY AND W. R. NEWBERRY.

HYDRAULIC cements, as is well known, are compounds of lime with the constituents of clay, and are obtained by burning natural or artificial mixtures of clay and carbonate of lime at a high heat, and grinding the resulting "clinker" to powder. Portland cement is made by preparing an artificial mixture of the materials, of correct composition, relatively high in lime, and burning the mixture at a white heat. Natural-rock cements are made from a limestone containing a high proportion of clay, and usually much magnesia, by burning at a low heat. The composition of modern Portland cements is remarkably uniform, as may be seen from the following table, taken chiefly from the circulars of the various factories:—

	Dyckerhoff. (German.)	Germania. (German.)	Porta. (German.)
Lime, CaO.....	63.75	66.04	62.28
Silica, SiO <sub>2</sub> .....	19.35	21.14	23.69
Alumina, Al <sub>2</sub> O <sub>3</sub> .....	7.00	6.39	7.30
Iron oxide, Fe <sub>2</sub> O <sub>3</sub> .....	4.50	2.59	2.87
Magnesia, MgO.....	Not det.	1.11	1.08

	Empire. (American.)	Saylor's. (American.)	Sandusky. (American.)
Lime, CaO.....	64.00	62.79	64.19
Silica, SiO <sub>2</sub> .....	20.80	20.64	23.20
Alumina, Al <sub>2</sub> O <sub>3</sub> .....	7.39	6.93	7.03
Iron oxide, Fe <sub>2</sub> O <sub>3</sub> .....	2.61	5.41	2.41
Magnesia, MgO.....	Not det.	1.72	0.97

Much has been written in regard to the probable reactions which take place in the burning of cement, and the nature of the compounds of lime, silica, alumina, and iron oxide of which the finished cement is composed. Most of the earlier work in this field is unsupported by experimental evidence, and even a brief synopsis of it would cover many pages. It is generally held that cement consists of basic silicates and aluminates of lime, which form crystalline hydrated compounds with water, thus causing the hardening of

cement. The part played by iron oxide and magnesia is obscure, and apparently of secondary importance.

The most complete study of the constitution of cements has been made by Le Chatelier (*Ann. des Mines*, 1887, 315). His experiments consisted of a careful microscopic examination of cement, both in the form of clinker and after hardening in water. He also made experiments on the artificial preparation of silicates and aluminates of lime, by heating mixtures of the pure materials. The most important of Le Chatelier's conclusions may be stated as follows:—

The monosilicate, CaO.SiO<sub>2</sub>, found in nature as Wollastonite, is not acted upon by water, and therefore plays no part in the hardening of cement.

The disilicate, 2CaO.SiO<sub>2</sub>, formed by heating chalk and powdered quartz in proper proportions, in a crucible, falls to powder on cooling, in the same manner as over-clayed cement clinker. This spontaneous pulverisation is due to a change of crystalline form (dimorphism).

The trisilicate, 3CaO.SiO<sub>2</sub>, cannot be obtained by heating a mixture of silica with three molecules of lime, a mixture of lower silicates and free lime being always obtained. The mixture heats and slakes with water, but after slaking sets slowly. In Le Chatelier's opinion this trisilicate may be formed indirectly, by heating lime and fusible silicates, and is the chief active constituent of hydraulic cements.

The mono-aluminate, CaO.Al<sub>2</sub>O<sub>3</sub> (lime spinel), is nearly infusible; sets rapidly with water.

The di-aluminate, 2CaO.Al<sub>2</sub>O<sub>3</sub>, is rather fusible, sets quickly with water, like plaster; but the mass, after setting, falls to pieces on boiling with water.

The tri-aluminate, 3CaO.Al<sub>2</sub>O<sub>3</sub>, is very fusible, and sets quickly with water.

The ferrites, made by heating mixtures of lime and iron oxide, all slake with water, and show no setting properties.

Hardened cement, according to Le Chatelier, consists of hexagonal plates of crystallised calcium hydrate, Ca(OH)<sub>2</sub>, embedded in a white mass of interlaced needle-shaped crystals of hydrated calcium monosilicate, CaO(SiO<sub>2</sub>).2½H<sub>2</sub>O. The chief reaction which takes place in the hardening of cement may therefore be represented as follows:—

Assuming that three equivalents of lime or magnesia, and no more, can enter into combination in cement with one equivalent of silica or alumina, Le Chatelier states that the proportion of lime and magnesia should not be less than the minimum—

$$\frac{\text{CaO}.\text{MgO}}{\text{SiO}_2.\text{Al}_2\text{O}_3} = 3,$$

nor greater than the maximum of—

$$\frac{\text{CaO}.\text{MgO}}{\text{SiO}_2.\text{Al}_2\text{O}_3.\text{Fe}_2\text{O}_3} = 3.$$

In these formulæ, equivalents, and not weights, are indicated.

The conclusions of Le Chatelier are reasonable, and agree closely with the practical results of cement manufacture. Le Chatelier's work certainly deserves the highest praise, and throws much light on some very obscure questions connected with the constitution of cements. Taking this work as a basis, it appeared to the authors very desirable to carry the experiments further, and ascertain, if possible, what proportions of lime, silica, and alumina will yield cement of the highest possible quality. It will be observed that Le Chatelier's formulæ indicate the correct amount of lime to be used with a given quantity of silica *plus* alumina. It does not appear from these formulæ, however, whether a highly silicious clay requires a different proportion of lime from one rich in alumina. It would also be of great interest to determine whether silicious or aluminous clays give the best practical result, the correct proportion of lime being employed in each case.

The questions which the authors have attempted to solve are as follows:—

1st. What proportions of lime must be employed for given percentages of silica and alumina in a clay?

2nd. Can a general formula be stated, applicable to all clays, which shall indicate the proportion of lime which will give the best result with each?

3rd. What effect has the presence of oxide of iron in the clay used on the proportion of lime required and on the quality of the resulting cement?

4th. Is the presence of alkalis in the raw materials necessary to the production of good cement?

5th. Is magnesia capable of replacing lime in cement mixtures, or is it inert, as has often been stated; and how does magnesia affect the quality of the cement obtained?

The plan followed in the efforts to solve these questions was that of synthesis with pure materials. These materials were as follows:—

1st. Silica: ground quartz, in impalpable powder, containing 99.49 per cent. silica.

2nd. Alumina, C.P. precipitated, containing 99.50 per cent. alumina, 0.20 per cent. soda, 0.05 per cent. iron oxide, and 0.25 per cent. silica.

3rd. Carbonate of lime, precipitated chalk, containing 99.7 per cent. calcium carbonate.

4th. Iron oxide, red, German C.P.

5th. Magnesia, German, C.P. containing only traces of silica, alumina, and lime.

All these materials were in the form of a perfectly impalpable powder, and none of them left any residue on a sieve of 180 meshes to the linear inch.

Mixtures of these materials, in calculated proportions, were made by rolling backward and forward on a large sheet of paper, then sifting three times through a 60-mesh sieve. The mixtures were then moistened with water, made into a cake, dried, and broken into small pieces for burning.

The burning was done in a Fletcher gas-furnace, using gasoline gas as fuel. To avoid contaminating the charge by the corrosion of the furnace, the fireclay cylinder was replaced by one of exactly similar shape, composed of basic material. This was made by mixing 21 oz. Portland cement clinker (passing a 20-mesh screen), 11 oz. Portland cement, 3 oz. plaster of Paris, and 1 oz. soda ash. The mixture was moistened with water and rammed into a suitable mould. After setting about a week under a damp cloth the cylinders were dried by gentle heat, and were then ready for use. Such cylinders stand repeated heating to a white heat, and are not in the least attacked by the charge. After use, they show, however, a tendency to air-slake, and crumble if left standing some weeks in the air. Good results were also obtained with cylinders cut from commercial magnesia brick.

The amount of material used in each experiment was about 300 grms. This was broken into small pieces and loosely piled into the furnace, thus being exposed to direct contact with the flame. The heat was varied to suit the material, an intense white heat being easily obtained with sufficient blast pressure. The burning of each charge occupied about an hour, or about one half hour after an intense and constant heat was obtained. On cooling, most of the material was found to be well sintered; the light-burned pieces on top were rejected.

It is generally agreed that cements of the highest strength and most vigorous hardening properties are those which contain the highest proportion of lime consistent with constancy of volume, *i.e.*, freedom from tendency to expand and crack. In these experiments the "high-lime limit" was determined by means of the *hot test*, by making a small pat of the cement, allowing it to set over night, and exposing it for four or five hours to steam at about 98° C. (208° F.). Tests were also made by placing the pats in steam as soon as made; this proved less severe and less

distinct than the plan of allowing the pats to set over night before exposure to steam. The results obtained were very distinct and striking, cements containing a very slight excess of lime showing marked expansion and cracking. In this manner the limit of lime which could be brought into combination could be fixed within 1 per cent. In most cases the pats were kept in boiling water for several hours after exposure to steam, but no additional information was thus obtained, since pats which remained sound for five hours in steam invariably continued sound in boiling water.

In addition to the hot and cold pat tests, tensile strength tests were also made in many cases. As the amount of material available for these tests was very small, briquettes  $\frac{1}{2}$  in. square or  $\frac{1}{4}$  sq. in. in section were employed. It was found that these gave approximately one-fourth the tensile strength shown by the same cement in briquettes of 1 sq. in. section. A German Portland cement gave the following results at seven days:—

	Lb.
Average of four $\frac{1}{4}$ sq. in. briquettes, 149 lb. $\times 4 =$	596
" " 1 " "	582

It is not claimed that the results of these tensile strength tests are of any especial significance; they were made simply in order to determine whether the artificial mixtures yield cements which compare favourably with commercial products. As the materials used were practically free from alkalis, which are supposed to play an important part in bringing about a good combination, this question appeared to be an interesting one. The results of these experiments will now be briefly stated.

#### I.—Proportion of Lime required for given Amounts of Silica and Alumina.

A. *Calcium Silicates*.—Mixtures of pure precipitated chalk and impalpable ground quartz were made in the proportion of 2,  $2\frac{1}{2}$ , 3, and  $3\frac{1}{2}$  molecules of lime to 1 of silica. These mixtures were burned at an intense white heat.

$2\text{CaO} \cdot \text{SiO}_2$ .—Chalk 200, silica 60. Clinker shrunken and sintered, translucent and crystalline. On cooling, fell entirely to powder, as described by Le Chatelier. Some of the pieces were quenched with water, by which the dusting was prevented. Dried and ground, these pieces yielded a white powder. A pat of this set slowly, showing good hardness at one day; very hard, on glass, at seven days. Hot test, sound; on glass, very hard.

$2\frac{1}{2}\text{CaO} \cdot \text{SiO}_2$ .—Chalk 250, silica 60. Clinker white, somewhat sintered, much shrunken. No sign of dusting on cooling. Pat showed very little setting quality, but hardened slowly in water; fairly hard at seven days, decidedly hard after six weeks. Pat placed in steam (after setting one day), hardened well; very hard, sound, and on glass after six hours.

$3\text{CaO} \cdot \text{SiO}_2$ .—Chalk 250, silica 50. Clinker white, shrunken, slightly sintered, no dusting. Powder showed no warming on mixing with water. Pat set fairly at one day, still rather soft at seven days, hard at six weeks. Hot test, sound; on glass, very hard.

$3\frac{1}{2}\text{CaO} \cdot \text{SiO}_2$ .—Chalk 256, silica 44. Clinker very little sintered, soft. No dusting. Pat set hard, but left glass curved slightly, and cracked before placing in water; became very hard after several weeks in water. Hot test, on glass, sound, hard.

These results may be most conveniently compared in the following tabular arrangement:—

#### Silicates.

Formula.	Ratio CaO to $\text{SiO}_2$ .	Per Cent. CaO.	Per Cent. $\text{SiO}_2$ .	Pat Test.	Hot Test.
$2\text{CaO} \cdot \text{SiO}_2$ .....	1:85	65.11	34.89	Set hard, hard 7 days, hard 6 weeks.	Sound; on glass, hard.
$2\frac{1}{2}\text{CaO} \cdot \text{SiO}_2$ .....	2:33	70.00	30.00	Set soft, fair 7 days, hard 6 weeks.	" " "
$3\text{CaO} \cdot \text{SiO}_2$ .....	2:80	73.68	26.32	" " "	" " "
$3\frac{1}{2}\text{CaO} \cdot \text{SiO}_2$ .....	3:27	76.56	23.44	Cracked, soft; hard 6 weeks.	" " "

These results are certainly very different from those obtained by Le Chatelier and described above. There appears to be no difficulty in obtaining a good combination of pure lime and silica up to the proportion of 3 mols. of lime and 1 of silica, provided the temperature is high enough, and the materials finely divided. Le Chatelier does not describe his methods of mixing and burning, and it is probable that his materials were heated in a crucible, and not in direct contact with the flame; in this case the temperature was doubtless much below that obtained in the authors' experiments.

While the combination of silica and lime appears to be complete, as shown by the constant volume of the product, both in cold water and in steam, the setting qualities of the higher calcium silicates are very slow. None of the products obtained, except the first, showed any decided set at one day, and the gradual hardening properties are more like those of hydraulic lime than Portland cement. According to Haunschild (Thonind. Zeit. 1893, 418) the hardest burned portions, called "Grappiers," of the celebrated Teit hydraulic lime have the following composition:—Silica, 23.6; lime, 64.7; alumina, 1.4; iron oxide, 0.8; magnesia, 1.4; sulphuric anhydride, 0.5; water, 7.6. These, when ground, form a white cement, largely used by cement-ware makers. The above analysis corresponds to a ratio of lime to silica of 2.74, or approximately the same as  $3\text{CaO} \cdot \text{SiO}_2$ . It will be seen later, however, that

the presence of even 1.4 per cent. of alumina is sufficient to greatly modify the character of the silicate.

**B. Calcium Aluminates.**—Mixtures of pure chalk and alumina were made in the proportion of 2, 2½, and 3 mols. of lime to 1 of alumina. As these mixtures proved to be very fusible, the charges were burned in a large platinum crucible placed in the Fletcher furnace. An intense heat was employed—about the same as in burning the silicates.

$2\text{CaO} \cdot \text{Al}_2\text{O}_3$ .—Chalk, 200; alumina, 102. Burned by direct heat, fused to a white slag. Burned in crucible, strongly sintered, semi-fused. Powder white. With water, heated strongly, set in a few seconds, like plaster. Pat, set hard; hard, on glass, after six weeks. Hot test, on glass, fairly hard, rather soft inside.

$2\frac{1}{2}\text{CaO} \cdot \text{Al}_2\text{O}_3$ .—Chalk, 250; alumina, 102. Burned by direct heat, fused. In crucible, semi-fused. Powder heated strongly with water, set quick. Pat, off glass at one day; curved and cracked at three days; soft, cracked at six weeks. Hot test, curved and cracked, soft.

$3\text{CaO} \cdot \text{Al}_2\text{O}_3$ .—Chalk, 300; alumina, 102. Burned in crucible, semi-fused. Powder heated strongly with water, set quick. Pat, curved and cracked before placing in water, disintegrated entirely in water. Hot test, curved and cracked, soft.

These results may be more easily compared by reference to the following table:—

#### Aluminates.

Formula.	Ratio $\text{CaO to Al}_2\text{O}_3$ .	Per Cent. CaO.	Per Cent. $\text{Al}_2\text{O}_3$ .	Pat Test.	Hot Test.
$2\text{CaO} \cdot \text{Al}_2\text{O}_3$ .....	1.10	52.38	47.62	Set quick, hard, sound 6 weeks.....	Sound; on glass, fairly hard.
$2\frac{1}{2}\text{CaO} \cdot \text{Al}_2\text{O}_3$ .....	1.37	57.85	42.15	Set quick, curved and cracked.....	Curved and cracked, soft.
$3\text{CaO} \cdot \text{Al}_2\text{O}_3$ .....	1.65	62.23	37.77	" " " " .....	" " " "

The above experiments lead to the following conclusions:—

1st. Lime may be combined with silica in the proportion of three molecules to one, and still give a product of practically constant volume and good hardening properties, though hardening very slowly. With  $3\frac{1}{2}$  molecules of lime to one of silica the product is not sound, and cracks in water.

2nd. Lime may be combined with alumina in the proportion of two molecules to one, giving a product which sets quickly, but shows constant volume and good hardening properties. With  $2\frac{1}{2}$  molecules of lime to one of alumina the product is not sound.

#### II.—General Formula for Cements.

Assuming that the trisilicate and di-aluminate are the most basic compounds which can exist in good cements, we arrive at the following formula:—

in which X and Y are variable quantities, having different values according to the relative proportions of silica and alumina present in the clay employed.

The formula  $3\text{CaO} \cdot \text{SiO}_2$  corresponds to 2.8 parts of lime by weight, to 1 part of silica.

The formula  $2\text{CaO} \cdot \text{Al}_2\text{O}_3$  corresponds to 1.1 parts of lime, by weight, to 1 part of alumina.

Substituting weights for equivalents, we have the following formula, representing the maximum of lime which should be present in a correctly-balanced cement:—

$$\% \text{ Lime} = \% \text{ silica} \times 2.8 + \% \text{ alumina} \times 1.1.$$

This formula may be used to calculate the proportion of lime which should be used with any clay of known composition, as follows:—

Multiply the percentage of silica by 2.8, and the percentage of alumina by 1.1; add the products; the sum will be the number of parts of lime required for 100 parts of clay.

As 2.8 parts of lime correspond to 5.0 parts of carbonate of lime, and 1.1 parts of lime correspond to 2.0 parts of

carbonate of lime, the calculation may take the following simple form:—

Five times the percentage of silica, plus twice the percentage of alumina = the number of parts of carbonate of lime required for 100 parts of clay.

As a practical example of the use of this formula, let us suppose a clay of the following composition:—

	Per Cent.
Silica.....	65.4
Alumina.....	16.5
Iron oxide.....	6.1
Lime.....	2.2
Magnesia.....	1.0
Moisture: combined water, &c. ....	7.9
	<hr/> 100.0

Let us now calculate the amount of lime (or carbonate of lime) which must be added to this clay to produce a correct cement mixture:—

	Lime.
% Silica = 65.4 × 2.8 =	183.12
% Alumina = 16.5 × 1.1 =	18.15
Total.....	201.27
Less lime contained in clay ..	2.20

---

199.07 parts of lime required for 100 parts of clay.

As 56 parts of lime correspond to 100 of carbonate of lime, we have—

$\frac{199.07}{56} \times 100 = 355.5$  parts of carbonate of lime required for 100 parts of clay.

The correct mixture would then be—

	Parts.
Clay.....	100.0
Pure carbonate of lime.....	355.5

The percentage of carbonate of lime in this mixture would be 78.0. On burning this, a cement of high quality will result, provided the materials are finely ground and perfectly mixed.

If we refer to the analyses of cements given at the beginning of this article, we shall find by calculation that the first two (German) cements correspond almost exactly to the proposed formula. The others show a slight deficiency of lime from the theoretical. It will of course be understood that the proposed formula represents the *maximum* of lime which can be used with safety. This maximum can be reached in practice only by most thorough grinding and mixing of the raw materials. Given these conditions, the more nearly the amount of lime approaches that called for by the formula, the higher will be the quality of the resulting cement.

It will be observed that the formula—

differs only from the minimum formula proposed by Le Chatelier in the number of molecules of lime assumed to be combined with one molecule of alumina.

Le Chatelier's formula may be written—

The difference in composition of cements made according to these two formulas is, of course, slight, especially when using a clay low in alumina. With high percentages of alumina, however, the difference is much more marked. If either of these formulae is correct, it should give the best results obtainable, when applied to either highly silicious or highly aluminous clays. It may here be mentioned that the common practice of expressing the composition of cements by the *ratio of lime to silicates* ( $\text{SiO}_2 + \text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ ) is very indefinite. With pure silica, according to the above formula, this ratio will be 2·8, while with pure alumina it will be only 1·1, and with clays of different relative proportions of silica and alumina this ratio will vary between wide limits. For example, applying the above formula, disregarding the iron oxide, to a kaolin and a silicious clay, we obtain the following:—

	Correct Ratio.
Kaolin (silica, 45; alumina, 40) .....	2·0
Silicious clay (silica, 70; alumina, 15) .....	2·5

This variation in the correct ratio of lime to silicates may be clearly seen in the table given below, in which the composition of cements prepared according to the proposed formula, with different relative proportions of silica and alumina, is given in full.

To determine whether the proposed formula—

or the first formula of Le Chatelier—

represents the correct proportion of lime in cements, a series of mixtures of chalk, silica, and alumina were prepared according to both formulae, burned, ground, and tested for constancy of volume and tensile strength. In these mixtures the composition was calculated so that the resulting cements should contain 2, 4, 7, and 12 per cent. of alumina respectively. It was found that the presence of even 4·2 per cent. of aluminate,  $2\text{CaO} \cdot \text{Al}_2\text{O}_3$  (2 per cent. alumina), was sufficient to give the tricalcium silicate excellent hardening properties, equal to those of the best cements. With increasing proportions of aluminate the clinker became much more fusible, the mixture containing 12 per cent. of alumina fusing to a semi-transparent slag, and yielding a quick-setting cement. This corresponds exactly with the results obtained in practice with aluminous clays, such mixtures having been found difficult to burn correctly, owing to their fusibility.

The clinkers obtained from these mixtures were faintly bluish-white in colour, and about like good Portland cement clinker in degree of sintering and hardness, except in the case of the mixture with 12 per cent. of alumina, which gave a hard, semi-fused clinker, difficult to grind. The cements obtained were perfectly white, and slow-setting except in the case of that with 12 per cent. of alumina. They set sharply and hardened well, showing qualities fully equal to those of the best cements. The cements containing 2 and 4 per cent. of alumina showed no noticeable heating on mixing with water. That containing 7 per cent. of alumina heated slightly, and that with 12 per cent. strongly. This behaviour, and also the increased quick-setting qualities with rising percentages of alumina, indicate that the aluminate, in presence of large amounts of silicate, behaves in the same manner as when free, and make it probable that the silicate and aluminate of lime in cements are simply mixed and not combined together.

The following tables show the results obtained with the two formulae under consideration. The tensile strengths given represent the average of two  $\frac{1}{2}$ -in. briquettes of neat cement, gauged with 22 per cent. of water, in each case. As already explained, the tensile-strength tests are not considered of any importance except as showing that the products are generally at least equal in strength to commercial Portland cements:—

Formula,  $X(3\text{CaO} \cdot \text{SiO}_2) + Y(2\text{CaO} \cdot \text{Al}_2\text{O}_3)$ .

The above tables show that the formula—

gives uniform and satisfactory results in point of hardening quality and constant volume with percentages of alumina ranging from 2 to 12 per cent. The product containing 12 per cent. of alumina is, however, quick-setting and low in tensile strength. A kaolin containing 15 per cent. silica and 40 per cent. alumina would, according to this formula, yield a cement containing 15.7 per cent. of alumina. The writers' experiments with kaolins from various sources show that they yield a very fusible clinker, difficult to burn uniformly and extremely hard to grind, while the resulting cements are quick setting and inferior in strength.

Turning now to the table showing the results yielded by the 1st formula of Le Chatelier—

we see that though the difference in composition as compared with the cements in the first table is slight, the high-lime limit has here been clearly passed, as shown by the bad results obtained in the hot test. The defects are more apparent as the percentage of alumina increases, the cement containing 12 per cent. of alumina proving unsound even in the cold pat test. From this it is evident that the allowance of 3 mols. of lime to one of alumina is excessive, and that the proposed formula, in which 2 mols. of lime are assigned to 1 of alumina, is more nearly correct.

### III.—Effect of Iron Oxide.

According to Le Chatelier, mixtures of iron oxide and calcium carbonate yield on burning products which slake with water and possess no hydraulic properties.

Dr. Schott (Dingl. Polyt. J. 202, 134 and 513) found that the alumina in cement could be completely replaced by iron oxide without injury to the hydraulic properties, and prepared cement containing only lime, silica, and iron oxide, which showed excellent hardening qualities.

In the hope of throwing some light on the rôle played by iron oxide in cement, a mixture of pure iron oxide, ( $\text{Fe}_2\text{O}_3$ ), and calcium carbonate was prepared according to the formula  $2\text{CaO} \cdot \text{Fe}_2\text{O}_3$ . On burning, the material fused to a black slag, which yielded a brown powder on grinding. Mixed with water to a paste, this powder showed no heating, and did not set or harden in air or cold water. A pat placed in steam, however, after setting one day in air, hardened rapidly, and after several hours in boiling water showed no cracking and appeared very hard.

From this experiment it appears that lime and iron oxide readily combine, yielding a product which is constant in volume, though it shows no hardening properties in the cold.

A mixture was then prepared according to the formula  $3\text{CaO} \cdot \text{SiO}_2 + 2\text{CaO} \cdot \text{Fe}_2\text{O}_3$ , containing 7 per cent. iron oxide. The result was as follows:  $3\text{CaO} \cdot \text{SiO}_2$ ;  $2\text{CaO} \cdot \text{Fe}_2\text{O}_3$ . Fusible, clinker black; powder, dark gray; pat, slow-setting, set hard; hard 28 days. Hot test, sound, hard, on glass.

It will be observed that the above cement contains only silica, iron oxide, and lime, no alumina being present. Except in colour, the resulting clinker and cement closely resembled that obtained from silica, alumina, and lime. It thus appears that iron oxide and alumina act in a similar manner in promoting the combination of silica and lime.

A number of mixtures were prepared according to the formulæ—

In the first formula no lime is assigned to the iron oxide; in the second formula the iron oxide appears with 2 mols. of lime. The percentages of alumina and iron in the mixture were 4 and 3 respectively. Both these mixtures gave perfectly sound and satisfactory cements, and no noticeable difference could be observed between them. In tensile strength, up to 28 days, formula No. 1 gave the better result.

Another mixture was prepared according to the maximum formula of Le Chatelier—

In this the percentages of alumina and iron oxide were also taken as 4 and 3 respectively. The resulting cement showed high tensile strength, but failed in the hot test. The pat placed in cold water also left the glass at 2 days, showing that the proportion of lime present was too high.

The percentage composition, and ratio of lime to silicates of the cements prepared according to the above formulæ, is shown in the following table:—

	Lime CaO.	Silica SiO <sub>2</sub> .	Alumina Al <sub>2</sub> O <sub>3</sub> .	Iron Oxide Fe <sub>2</sub> O <sub>3</sub> .	Ratio Lime to Silicates.
1.....	69.68	22.32	4.00	3.00	2.29
2.....	70.23	22.77	4.00	3.00	2.34
3.....	71.09	21.91	4.00	3.00	2.46

As above stated, Nos. 1 and 2 gave cements which stood the boiling test well, while No. 3 failed.

From the close similarity in the composition of cements No. 1 and No. 2, it is evident that it is quite unnecessary, in working with ordinary clays, to take the iron oxide into consideration in calculating the amount of lime required. Iron oxide evidently combines with lime in the same manner as alumina. The amount of iron oxide present in ordinary clays is, however, so small, and the amount of lime with which it will combine so insignificant, that the effect of ordinary proportions of iron oxide in cements is extremely difficult to trace.

### IV.—Effect of Alkalies.

Most writers on the cement industry have assumed that alkalis, potash, and soda play an important part in bringing about the combination of lime with silica and alumina, and the artificial addition of alkalis to materials deficient in them is often recommended. The writers' experience has been, however, that no advantage results from this addition, and Feichtinger states the same. The foregoing experiments show that pure silica, alumina, and lime, free from alkalis, combine readily to produce well-sintered clinker, and that the fusibility of the clinker depends chiefly on the proportion of alumina or iron oxide present. It thus appears unlikely that alkalis have any important action.

In order to test the effect of soda on the combination of silica and lime, two mixtures were prepared according to the following formulæ:—

5 per cent. soda was taken in both cases. The results were as follows:—

1. Soda largely volatilised. Clinker soft, light, infusible. Powder heated strongly with water. Pat swelled and cracked before placing in water. Hot test swelled, soft.

2. Clinker soft, light, infusible. Powder did not heat with water. Pat set fairly; swelled and cracked after two days in water.

It is interesting and rather surprising to note that while the tricalcium silicate,  $3\text{CaO} \cdot \text{SiO}_2$ , proved to be of constant volume, though of feeble hardening properties, the same with the addition of sodium silicate gave a product which swelled and cracked.

It appears from the above experiments that soda is incapable of assisting in the combination of silica with high proportions of lime.

### V.—Effect of Magnesia.

The question of the influence of magnesia in Portland cement has been studied by many chemists, and is now undergoing careful investigation by the Association of German Portland Cement Manufacturers. Several eminent authorities hold that the presence of considerable percentages of magnesia causes cement to expand and crack after long periods. The most thorough work on this subject is

doubtless that of H. Dyckerhoff, presented to the German Association in 1895 (this Journal, 1890, 943). According to Dyckerhoff's experiments, more than 4 per cent. of magnesia, whether added to a normal mixture or substituted for an equivalent amount of lime, causes a steady falling off in the strength of the resulting cement. Actual cracking was observed only with 8 per cent. or more of magnesia. As stated above, this question is now being most exhaustively studied by a committee of the German Association, who have laid out a series of experiments and observations, which will require five years to complete. In view of this, the writers have not attempted to investigate the injurious practical effects of magnesia.

There is another aspect of the question, however, which is of great importance to cement chemists, and that is, the influence of the presence of magnesia on the proportions of lime and clay required to produce a correct mixture. If magnesia replaces lime and combines with clay, as indicated by the formulae of Le Chatelier, it must, of course, be allowed for in the calculation of the mixture. If, however, magnesia is inert, as some have maintained, it may be disregarded, and the clay used may be proportioned to the lime alone. A number of experiments were tried in the hope of throwing light on this question, and though the work is incomplete and not yet conclusive, some interesting facts were brought out which may well be briefly stated.

The first question to be studied is, whether magnesia forms with silica and alumina any compounds possessing hydraulic properties. It is well known that pure magnesia, calcined at high heat, sets with water and hardens like cement.

Pure magnesia (German C. P.) was moulded into cakes with water, dried, and burned one hour at a white heat. The resulting clinker was much shrunken, brittle, and hard to grind. The powder, made into a pat with water, set slowly, hard at one day; very hard but slightly cracked at the edges after several days in water. Under hot test the pat curved and cracked.

The same material, pure magnesia, burned in a crucible at bright yellow heat, showed only slight hydraulic properties and hardened fairly. The hot test remained soft.

It thus appears that pure magnesia, calcined at a high temperature, possesses decided hydraulic properties, but is not constant in volume.

**Magnesium Silicates and Aluminates.**—Several compounds of magnesia with silica and with alumina occur in nature as minerals, and therefore would not be expected to show any hydraulic properties. Among these may be mentioned: Spinel,  $MgO \cdot Al_2O_3$ ; Enstatite,  $MgO \cdot SiO_2$ ; Forsterite,  $2MgO \cdot SiO_2$ .

It will be remembered that the mono-aluminate and disilicate of lime show decided hydraulic properties. It is therefore evident that magnesium compounds differ decidedly from those of lime in their behaviour towards water.

Artificial compounds of magnesia and alumina were prepared by mixing pure magnesia and alumina in the proportions:  $MgO \cdot Al_2O_3$ ,  $2MgO \cdot Al_2O_3$ ,  $3MgO \cdot Al_2O_3$ , and burning at a white heat. None of the mixtures showed any sign of fusing or sintering, and the calcined products were in all cases light, porous, and soft. On pulverising and mixing with water none of the pats showed any tendency to set, and after several days in moist air all were still soft, and turned to mud when placed in water. Neither of the magnesium aluminates showed any tendency to harden in steam.

Artificial magnesium silicates were prepared from pure magnesia and silica, and burned at the highest white heat of the gas-furnace. The results were as follows:—

$MgO \cdot SiO_2$ . Semifused, clinker hard, like porcelain. Powder showed no setting or hardening qualities in air, water, or steam.

$2MgO \cdot SiO_2$ . Well sintered, clinker porous, rather hard. Powder showed no setting or hardening properties in air, water, or steam.

$3MgO \cdot SiO_2$ . Infusible, slightly sintered, clinker porous, soft. Pat seemed to harden slowly in moist air, but after several days in air turned to mud on placing in water. No setting in steam.

From the above experiments it is evident that the compounds of magnesia with alumina and silica have no hydraulic properties, and it is quite unlikely that they play any part in the hardening of cements. Whether the tribasic silicate and aluminate exist as chemical compounds is very doubtful.

**Action of Magnesia on Clay.**—At the suggestion of Dr. Aug. Dyckerhoff, experiments were undertaken to determine whether magnesia has the power of decomposing clay, when calcined with it, and rendering the silica of the clay soluble. The action of lime on various forms of silica has been studied in a most interesting way by Lunge (Thonind. Zeit. 1894, 655), who found that the silica of kaolin is rendered entirely soluble by calcining with lime, while precipitated and crystalline silica are less completely acted upon, the extent of the action increasing rapidly, however, with increasing fineness of division of the silica. Lunge's method consists in repeatedly digesting the product of the calcination with dilute hydrochloric acid (20 per cent.), and a 20 per cent. solution of sodium carbonate. By this treatment the lime and the silica which has been rendered soluble are dissolved out, while the uncombined silica remains unattacked (this Journal, 1895, 37).

For the experiments with magnesia, a clay of the following composition was taken:—

Loss on ignition .....	7.46
Silica .....	65.41
Alumina .....	16.54
Iron oxide .....	6.06
Lime .....	2.22
Magnesia .....	1.88
	99.57

A sample of this clay was ignited at a red heat, finely pulverised, and 1 grm. treated with hydrochloric acid and sodium carbonate, according to Lunge's method. The residue was 96.24 per cent., showing a loss on digestion of only 3.76 per cent.

A mixture of clay and carbonate of lime was then prepared, corresponding with the formula—

This consisted of 100 parts of clay and 356 parts of calcium carbonate. Burned at a high heat, a grey-green, well sintered clinker was obtained. This was ground and treated with hydrochloric acid and sodium carbonate. The residue was only 0.4 per cent., showing that practically all the silica of the clay was rendered soluble by calcination with lime.

A mixture of clay and magnesia was then prepared, in the proportion required by the formula—

the lime in the last experiment being replaced by an equivalent quantity of magnesia. The mixture consisted of 100 parts of clay and 144 parts of magnesia. Burned at a high heat, a reddish clinker, partially sintered, was obtained, which yielded a pink powder on pulverising. This showed no hydraulic properties on mixing with water.

Allowing for the loss on ignition of the clay, the composition of this mixture, after calcination, should be—

Magnesia .....	60.87
Clay .....	39.13

One grm. of the calcined mixture was then treated with hydrochloric acid and sodium carbonate solution. The residue was 10.14 per cent. or about one-fourth of the clay present. Analysis of the solution and residue gave the following:—

Solution—	
Silica .....	27.12
Iron oxide and alumina .....	15.26
Magnesia .....	48.36
Residue—	
Silica .....	6.63
Iron oxide and alumina .....	2.23
Magnesia .....	1.43
	101.03

From the above experiment it appears that magnesia decomposes clay when calcined with it, but that the action

is far less complete than in the case of lime. The product of the calcination of magnesia and clay has, however, no hydraulic properties, and cannot take part in the hardening of cement.

**Proportion of Clay required with Magnesians Material.**—In order to determine conclusively whether magnesia should be allowed for in calculating the proportion of clay required for use with magnesian materials, experiments were tried with a dolomite lime (air-slaked), of the following composition:—

	Per Cent.
Lime, CaO.....	43.5
Magnesia, MgO.....	31.0
Loss on ignition.....	25.0
Total.....	99.5

By calculation it is found that to convert all the lime into cement according to the formula stated, leaving the magnesia free, 21.6 parts of clay (analysis given on page 892 or preceding) will be required for 100 parts of dolomite lime.

A mixture was prepared in these proportions, and burned. The clinker was dark green and well shattered. The cement was yellowish in colour, slow-setting, and hardened well in water, appearing sound at 28 days. The hot test was perfectly sound, the pat remaining on the glass.

In this cement the ratio of lime *plus* magnesia to silica *plus* alumina is 4.46, an immense excess over that called for by the formula of Le Chatelier, in which the magnesia is assumed to act like lime. It is probable, as indicated by the experiments of Dyckerhoff and others, that this cement will show expansion and cracking after some time, and its behaviour in this respect will be carefully watched. This defect, however, as shown by the hot test, will be due to presence of a high proportion of magnesia, and not to excess of lime or deficiency of clay. (See also this Journal 1890, 1037.)

Another mixture, consisting of 100 of dolomite lime with 18 of clay, gave pats which curved and cracked, both in steam and in cold water.

It thus appears that the proposed formula is applicable to magnesian materials, as well as those free from magnesia, also that the magnesia should not be considered in calculating the amount of clay required.

#### Summary.

The conclusions to which the writers are led by the above experiments may be briefly stated as follows:—

1. The essential constituents of Portland cement are tricalcium silicate with varying proportions of di-calcium aluminate. This composition may therefore be expressed by the formula  $X(3CaO.SiO_2) + Y(2CaO.Al_2O_3)$ . From this formula it may be calculated that the correct proportion of lime, by weight, in Portland cement, is 2.8 times the silica *plus* 1.1 times the alumina.

2. Iron oxide combines with lime at a high heat, and acts like alumina in promoting the combination of silica and lime. For practical purposes, however, the presence of iron oxide in a clay need not be considered in calculating the proportion of lime required.

3. Alkalis, so far as indicated by the behaviour of soda, are of no value in promoting the combination of lime and silica, and probably play no part in the formation of cement.

4. Magnesia, though possessing marked hydraulic properties when ignited alone, yields no hydrochloric products when heated with silica, alumina, or clay, and probably plays no part in the formation of cement. It is incapable of replacing lime in cement mixtures, the composition of which should be calculated on the basis of the lime only, without regard to the magnesia present.

#### DISCUSSION.

The CHAIRMAN stated that a number of years ago it had devolved on him to look up the literature on cement, and the analysis more especially. The literature then at his command was not very extensive. He eventually appealed to the Astor Library, but in almost all the analyses he saw of the hydraulic cement none seemed to go above 90 per cent. The remaining 10 per cent. were left to the choice of the cement maker.

Dr. NEWBERRY said he would like to add one thing which he had forgotten to mention. He had put on the board Le Chatelier's formula for the hardening of cements. It was a little hard to believe that those effects took place, and he would merely point out that they were engaged in a series of experiments on that subject which he hoped would soon throw some light on it. They should all acknowledge their obligations to Le Chatelier, who had done the first and most complete work in this field, but that what they hoped to do was to carry that still further and to apply Le Chatelier's microscopic study of the cement clinker and the hardened cement to materials of absolutely known composition; to take the dry calcium silicate without the presence of the aluminium and magnesium silicates, and all the things which confuse it, and submit it to microscopic study during its hardening. They were already carrying on some work in that direction, and when finished they hoped to be able to contribute something to the knowledge of how cement hardened. Their work had previously been devoted entirely to low cement combined.

Dr. F. VAN DERROET asked the reason for having the amount of water in Le Chatelier's formula an unknown quantity, when it appeared in the second member of the equation as a known quantity.

Dr. McKENNA said that the review of Le Chatelier's work just presented by Dr. Newberry was a lucid and valuable one and the experiments with which he had followed it up and those which he had in view were really of great value. There was considerable work of that kind needed. It was viewing the subject from a very high plane; the behaviour of these ideal mixtures was very instructive. He thought that in practice the composition of good cements could not be placed within narrow limits. Dr. Newberry had mentioned that the lime should be from 62 to 65, the silica from 20 to 23, and the alumina 6 to 7; but it was found that some good cements varied. Thus, they could run higher in silica, changing the proportions of the other elements and yet not suffer. Silica could also play the part of a beneficial agent and actually combine with the lime and harden thus and not by hydration. This was the action which took place in puzzolanous cements, but, of course, although a good cement, it would not be one of these ideal Portlands. Perhaps thermo-chemistry would yet tell us more as to the most probable combinations from cement of a given composition.

Very little was known of a certainty regarding magnesia, particularly in the case of cement immersed in water—sea-water. There were many situations in which cements were placed; but the experiments of the German Manufacturers' Association were almost solely on the subject of its influence when immersed in sea-water. This was, of course, its most important application. Cases of cements with high percentages of magnesia were recorded, which were still very sound after a long time. This was only another instance of the fact that in practice they had much to learn.

Dr. WM. JAY SCHIEFFELIN asked Dr. Newberry whether in the last experiments mentioned with the dolomite he had also tried whether magnesia would require the silica in calcining.

Dr. L. N. ADLER said he had seen it stated that magnesia when heated still had the capacity of taking up water, and asked whether there was any truth in that statement, and whether that might not account in a measure for the fact that a cement containing 32 per cent. of magnesia still had the necessary properties possessed by cements containing only 8.

Mr. CLIFFORD RICHARDSON said he would like to express his great appreciation of the value of Prof. Newberry's paper. It seemed to him to mark an epoch in the history of the cement industry, and it was encouraging to see that this work had been done in connection with the establishment of the industry in the United States. It was particularly important, in that it enabled us to judge accurately of the value of a clay for the purpose of cement making, and to determine the highest amount of lime which it could combine with, thus putting the industry on a more rational footing than it ever has had before.

Mr. S. A. TUCKER said it seemed to him that at the very high temperature necessary, to bring out the effects of the hydraulic properties of magnesia, the electrical furnace product might be very variable.

Dr. EDEMANN, in reply to a statement that dolomite would give very excellent hydraulic cement, said that he had made experiments in connection with the manufacture of liquid carbonic acid gas from dolomite found in Westchester county, which could be had at a nominal price. The carbonic acid was obtained by passing steam over the dolomite in retorts while the retorts were heated to redness. In that way he found that just one-half the carbonic acid would be driven off and one-half remain behind with the lime. He made experiments with the product thus obtained to find whether it had really hydraulic properties, and had found it absolutely valueless for the purpose.

Mr. M. TOWN said that when cement was used in sandstone and limestone buildings, a great many free soluble salts found their way to the surface of these stones and in the course of time defaced the surface of the buildings. These soluble salts had come to his notice in some very peculiar combinations. Several sandstones he examined showed calcium oxalate as the result of the use of cement. It took him a long time to find out how calcium oxalate was produced. He could at once account for magnesium sulphate, which was caused by the presence of pyrites in the coal used for burning the cement. Calcium oxalate appeared to be produced in cements through the action of a certain fungus—the *penicillium glaucum*. Carbonic acid from the air combined with lime and moisture at a favourable temperature to form calcium oxalate,  $\text{CaC}_2\text{O}_4$ , showing that certain micro-organisms possessed synthetic powers as well as analytic powers. Thus calcium oxalate was produced on the surface of limestone indirectly through the cement. Again, calcium fluoride, which had worked its way to the surface and formed a white florescence, was treated by a builder with hydrochloric acid, forming calcium chloride, on which thrived the green alga "*Protococcus viridis*," known as the green fungus, found on the north side of trees and on brown stone and sometimes on buildings after a rainy spell. When this micro-organic plant rooted itself on calcium chloride there was no way that he has ever heard of in which it could be destroyed. These two peculiar instances were directly traceable to cement.

Dr. S. B. NEWBERRY, in answer to Dr. Vanderpoel, replied that he thought that Le Chatelier meant to imply that there should be an excess of water. In answer to Dr. Schieffelin, the author replied that they had tried that experiment, and the result was a failure. The material was no good as a cement. In answer to Dr. Adler, the author replied that Dyckerhoff stated that magnesia calcined at a high temperature was not constant in volume but was very dense, and when it took up its water, as it ultimately did, it expanded, but did so very slowly; but that magnesia calcined at a lower heat would readily combine with water, and did not swell; that is, it took up water before it set and hardened. Dr. Adler presumably wished to show that injury might arise where cement was calcined at a high temperature, whereas if calcined at a lower temperature it would not show itself. It well known that most common American cements, such as those made from natural rock, containing lime and from 15 to 20 per cent. of magnesia, did not perceptibly crack or go to pieces. Dyckerhoff explained that by saying if Portland cement were calcined at a white heat the magnesia would be very injurious. As to the effect of calcining pure magnesia, they did not find (although he had seen it stated in text-books) that if calcined at a moderate heat it would have hydraulic properties. Calcined at a cherry heat it had very feeble hydraulic properties. After calcining at a white heat, although it hardened very slowly, it became eventually quite hard. There was another reason that must be noted, viz., if the temperature were too high it would fuse down and probably fail to test; it would have no hydraulic properties.

In answer to Mr. Tucker, the author replied that he had never seen the product of an electrical furnace. It would be very interesting to see whether that extremely high temperature had modified these hydraulic properties at all.

## ON THE ESTIMATION OF SMALL AMOUNTS OF $\alpha$ -NAPHTHOL IN COMMERCIAL $\beta$ -NAPHTHOL.

BY JOHN PROCHAZKA AND H. N. HERMAN.

THE following method for the determination of  $\alpha$ -naphthol in  $\beta$ -naphthol was discovered in the works of the Heller and Merz Company more than two years ago, because a shipment of  $\beta$ -naphthol received at that time, being worked up for colouring matter in the usual manner, failed to give a product of the usual quality. Nor was the true cause of the trouble at once suspected. It was only by a logical analysis of all the conditions of manufacturing that the true cause of trouble was traced to the presence of certain impurities in the  $\beta$ -naphthol employed, impurities which were found to be absent in the lots of  $\beta$ -naphthol that had been used before.

A method for the determination of  $\alpha$ -naphthol in  $\beta$ -naphthol has been described by Dr. A. Liebmann before the Manchester Section of this Society, and is published in the April number of the current year.

The principle there applied is identical with the principle underlying our method, and consists in the property of  $\alpha$ -naphthol combining more readily with diazo bodies than  $\beta$ -naphthol, forming bodies generally more soluble.

The body recommended by Dr. Liebmann for the purpose of determining  $\alpha$ -naphthol in  $\beta$ -naphthol is the diazo compound of *p*-nitraniline, the body we have found expedient to use is the diazo derivative of the 1-4-naphthylamine sulphonic acid, generally called naphthionic acid.

The diazo compound needed for this test should be carefully prepared as follows:—

27½ parts by weight of 90 per cent. of sodium naphthionate are dissolved in 185 parts of water. 6·2 parts by volume of 66° of oil of vitriol are diluted to 30 times their bulk and run slowly into the naphthionate solution, which is continuously stirred to secure a uniform paste. Then cool off the mixture to below 5° C. and add slowly, stirring carefully, a 10 per cent. solution of sodium nitrite, containing 7 parts of the commercial 98 per cent. product. The resulting paste is made up to a volume of 750 parts of water and is now ready for use.

The solution of  $\beta$ -naphthol to be tested is prepared as follows:—

15 parts by weight of  $\beta$ -naphthol;  
200 parts by weight of 25 per cent. of caustic soda solution;

140 parts by volume of 10 per cent. of soda ash solution; are heated together until the  $\beta$ -naphthol is completely dissolved. The solution is then made up to 250 parts by volume, and cooled off to a temperature below 5° C. before use.

The diazo compound is now run slowly and carefully into the  $\beta$ -naphthol solution, which is continuously stirred during the process of mixing.

If the  $\beta$ -naphthol is pure, the resulting azo compound will precipitate completely in the shape of a fine crystalline powder, and hardly any colour will pass into solution, while the first portions of the diazo compound are being added. On the contrary, if  $\alpha$ -naphthol be present in any appreciable quantity a coloured solution is formed beside the crystalline powder above mentioned. Even where the percentage is less than  $\frac{1}{10}$ th the presence of  $\alpha$ -naphthol will reveal itself by the peculiar bluishness of the tinge imparted to the solution. If the rest of the diazo compound is added, the presence of the  $\alpha$ -naphthol compound is obscured through the formation of a thick colour paste. However, by boiling the product the paste is made to settle in the shape of a layer of fine crystals, and the supernatant liquid is more or less coloured with the  $\alpha$ -naphthol compound. From the phenomena previously mentioned, the following short method was finally deduced:—Instead of combining the whole of the  $\beta$ -naphthol, only a part, say, 5 per cent. of the whole, is combined with diazonaphthalene sulphonic acid. The diazo paste prepared as above is well shaken and 37½ parts by volume run into the  $\beta$ -naphthol solution, the same quantity as above, and with the same precautions as already described. It is then not necessary to boil the product, as the insoluble colour formed settles readily, and by dipping strips of filtering paper into the supernatant liquid, and

comparing the tint with that obtained similarly from mixtures of pure  $\beta$ -naphthol with a known percentage of  $\alpha$ -naphthol, a fairly accurate idea of the amount of  $\alpha$ -naphthol present can be obtained. The method can be further simplified by using colour solutions of known strength and same shade as that of the above coloured filtrate, for the purpose of comparison. The method is more reliable, if moderately large samples are used, but with proper caution can be successfully applied to quantities less than 1 gram.

It is a gratifying sign of the progress of chemical industry that  $\beta$ -naphthol, almost entirely free of  $\alpha$ -naphthol, can be had in commerce at a price only slightly above that of the impure article.

#### DISCUSSION.

Dr. H. ENDEMANN said that he had used the method just described on known mixtures and had found it work well. Did the author know the nature of the substance which is dissolved in an alkaline solution with blue colour?

Dr. ENDEMANN said that the colour obtained in that way from  $\alpha$ -naphthol was a brown, and that the solution of the brown did not become blue in the presence of an alkali—at least not according to the table, which gave the reactions. He thought it could not be that substance, but might perhaps be another derivative.

Dr. SCHWEIZER inquired whether the author claimed that the employment of naphthionic acid for paranitraniline had any advantage? He considered the use of alcohol and toluene in Liebmann's method rather objectionable. He thought, however, that the use of paranitraniline for naphthionic acid must be an advantage, because in the one case they had a soluble diazo compound and in the other the insoluble diazonaphthionic acid. He only called attention to the insolubility of diazonaphthionic acid, and theoretically would be of opinion that a combination of the Liebmann and Prochazka test might be of advantage.

Mr. J. PROCHAZKA, in answer to Dr. Endemann, replied that he believed it to be the compound of the  $\alpha$ -naphthol, which was soluble and very bluish, and perhaps it might be a diazo-derivative. The method described by Dr. Liebmann prescribed the use of alcohol and toluene, so that under certain circumstances this method might be more convenient. His method would not be more advantageous for everybody, but having conveniently at hand large quantities of diazonaphthalene sulphonic acid, it was more convenient, and he thought it might prove so for a great many.

#### A NEW CHROME MORDANT ON ANIMAL FIBRE.

By O. P. AMEND.

INASMUCH as all persons familiar with the art of dyeing will readily concede that the methods for mordanting now generally in practical use are subject to serious defects and objections, it is most gratifying that a process has recently been found by which all of these defects and objections are practically obviated. The injuries resulting from the old (boiling) mordant bath were in some cases so serious that, for many reasons, some dyers preferred to use colours which would combine with and develop on the fibre without the use of a mordant, although such colours are, as a rule, inferior to colours produced on mordanted material. For the benefit of those not practically experienced in the art of dyeing, a short description of the mordanting, under the old, as well as the new method, will no doubt be interesting.

By mordants we mean chemicals that will form combinations with the fibre, and these combinations of the fibre and chemical will again combine with, or form a lake with, the dyestuff or colours in the subsequent dye-bath. The colours so produced are, as a rule, very fast to light and washing, and do not crock. The salts of aluminium, chromium, copper, cobalt, iron, nickel, manganese, and other chemicals have been employed for this purpose, but the most important by far is chromium. It is usually employed in shape of a chromic salt, such as bichromate of potash or soda. Acetate and fluoride of chromium have been suggested, and are used to some extent. The above-mentioned bichromates, however, still seem to be in general use. Along with the bichromates a secondary acid salt or free acid is used. The object of this addition is to produce

a reduction and decomposition of the bichromate employed, in order that the so reduced bichromate may be deposited on and combined with the fibre. Various compounds have been employed for this purpose. Bitartrate of potash or argols and oxalic acid are preferred in alizarin dyeing; sulphuric acid, lactic acid, and the lactates are preferred in case of logwood dyeing. A new method has been suggested in Germany, by which the bichromates are first decomposed by means of sulphuric acid, after which lactic acid or a lactate is added in order to still more reduce the so-decomposed bichromate. It will be seen that the object of all these secondary acid salts and acids is to produce as complete a reduction of the chromium salt on the fibre as is possible. None, however, obtain this much-sought-for result in a perfectly satisfactory manner. On examining the mordants so produced a yellowish tinge can always be observed, this being due to an incomplete reduction. E. Knecht (in Hummel and Knecht) has proposed to reduce the remaining chromic compounds by means of a warm solution of bisulphite of soda.

The object of the new mordant (Amend process) was to combine chromium with animal fibre in such a way as to leave the fibre in its most natural state, and in order to obtain this result, boiling had to be avoided. It was found that free chromic acid combined with animal fibre at ordinary temperatures. The nature of this chemical combination has not been definitely determined, for the simple reason that the chemical composition of animal fibre is not thoroughly known. But if a classification was to be made this new compound would be placed under the heading of a chromic salt, the animal fibre taking the place of the base, in fact, it might be compared with some of the more sparingly soluble bichromates.

To show how similar the reactions of this new chromic acid animal fibre compound are to the inorganic bichromates, may be illustrated by its action towards the aromatic amines. It is well known that bichromates acting on aniline or its salts produce so-called aniline blacks. The same reaction takes place when using this new chrome fibre compound. The aniline black thus produced is formed on the animal fibre, thereby producing a fast black on furs, wool, &c. It has been laid down in all the literature on this subject, that no satisfactory aniline black could be produced on animal fibre, on account of the reducing action of the latter. Nolting and Leber (page 57, *Anilinschwarz und seine Anwendung*, &c.) in describing a proposed process for aniline black on wool or silk, quote:—"Dieses Verfahren ist ebenso unpraktisch wie alle übrigen bisher zum färben der Wolle vorgeschlagen."

This reducing action has been explained by various authors in many different ways, but whatever may be the cause of the same, it is a fact that it has been overcome in the new chrome fibre compound.

As the chromic fibre compound was of such great value in producing a fast aniline black, the next step was to produce a chrome oxide fibre compound, by simply substituting some other reducing agent in place of the aromatic amines. It was found that any of the well-known reducing agents could be used, and after a great number of trials, sulphurous acid, in shape of the commercial solution of bisulphite of soda, proved to be the most practical. The chromic acid animal fibre compound is subjected to a very dilute solution of bisulphite of soda, and thereby reduced to a chrome oxyhydrate animal fibre compound. As this reduction takes place at ordinary temperature and in very dilute aqueous solutions, it is easily seen that the fibre is not acted upon in any injurious way. The bright yellow chromic acid compound is now converted into a bluish-green chrome oxyhydrate compound. It had always been the object of the dyer to produce a chromated fibre with as little injurious action in the latter as possible. Although they used the chemicals in very dilute solutions, a temperature of the boiling point of water was necessary during the mordanting operation, which lasted from 1 to 1½ hours. This certainly had an injurious action on the fibre, such as felting, weakening, loss in weight, and harsh feeling. The new process overcame these difficulties as the solutions employed were still more dilute and were applied at ordinary temperatures.

It was shown by actual analytical research that any of the old boiling mordanting methods had injurious effects on the fibre. The boiled fibre was found to have lost from 1 to 2 per cent. up to 2½ per cent. of its actual weight, according to the material employed; consequently the hot mordant rendered a part of the material soluble, thereby changing its chemical composition. The loss expressed in percentage does not seem great, but in converting it to practical figures it shows as follows:—In a mill dyeing 10,000 lb. of wool a day, and supposing the average loss to be 1 per cent., it would represent a loss of 100 lb. of wool per day, which loss is due to the extracting action of the boiling mordant bath.

Any practical comparative tests between the old boiling and the new mordant, will show great physical differences, so far as elasticity, feel, and appearance of the surface are concerned.

In the new process, invented by Mr. O. P. Amend, the loss in weight of the wool is scarcely appreciable, and this would prove conclusively that no destructive change has taken place. The second action of the old mordant boiling bath is an oxidising one, which can easily be demonstrated in an unmistakable way, by applying such mordant to a so-called indigo-bottomed material. Although indigotine is quite a stable compound, it is oxidised by this hot mordant to a large extent, and it is therefore self evident, that the much weaker animal fibre must necessarily suffer to a still greater degree. By applying the new Amend mordant to the same indigo-bottomed wool no perceptible change takes place, the indigotine is not oxidised, and therefore it is safe to assume that there is no oxidising action on the fibre. It is well known in the art of dyeing that the harsh and brittle properties of the fibre are due to oxidation, such that explains the superior qualities as to the feel and textile strength of fibre mordanted according to the Amend process, when compared to that mordanted in the boiling bath. The fibre resulting from hot mordant always produces a material of inferior spinning qualities, while that mordanted according to the Amend method shows no perceptible change from the original fibre (show slubbing).

It was found that chromic acid combined very readily with animal fibre in very dilute solutions (the solution containing  $\frac{1}{10}$  of 1 per cent. of chromic acid), and that almost the theoretical amount (that is to say, about 97 per cent. of chromic acid) was taken up by the fibre in presence of a secondary acid (the amount of such acid employed being one-tenth of 1 per cent.). This secondary acid also proved to be of value in the reducing step of the process. Knowing that chromic acid combined with animal fibre at ordinary temperature, the next question to be considered was: Would this secondary acid, or part of it, also combine with the fibre at ordinary temperature? That acids combined with animal fibre at the boiling point of water is known, and is so stated by Hummel and Knecht. It was found by analysis that 66 per cent. to 70 per cent. of the secondary acid employed combined with the fibre. The next step was to get rid of this acid so as not to interfere in the subsequent dyebath. Could it be removed by simple washing, or would it be more practicable to remove it by means of a chemical agent? Both ways proved successful.

After this treatment we have the chrome-oxyhydrate in its pure form on the fibre, free from chromic and all other acids; and we have before us the ideal form of a lake-forming mordant. The application of the alizarine series in ammoniacal solution (this renders them more soluble and thereby admits of a more even and penetrating dyeing) has always been the desire of the dyer, and the new mordant is especially adapted to this method. A short reflection will show why any of the old chrome mordants will not answer as well. It has been admitted by all authorities, that in the old styles of mordanting, the fibre contains chromic acid, chromic salts, or combinations of chrome which are easily acted upon by ammonia or alkali, and therefore the dyeing in such alkaline baths was rather difficult and very uncertain. That the new mordant, after having been washed by an alkali, is free from all the above-mentioned objections, is self evident. The conclusive proof of this assertion can easily be shown in an experimental way. Show: It will be seen that any of the old mordants

treated with distilled water will colour the water a yellowish tinge due to soluble chromic acid compounds, whereas the new mordant does not give up anything to the distilled water. The same reaction will take place in a more vigorous manner in the hot dyebath, that is to say, the old mordant will give off a part of its chrome in soluble form, which will necessarily produce precipitates or lakes with the dyestuff in the dyebath, thereby producing a so-called smutting of the material. This involves not only a loss of colouring matter employed, but it also produces colours which will not stand a thorough scouring or stand a severe crocking test.

Now let us look at the product of the new Amend mordant. The first thing one's attention is drawn to, is the condition of the dyebath, and here the most striking illustration is given in case of the logwood dyebath, logwood being the most delicate and difficult dyestuff. In using any of the hot mordants, the logwood bath will turn an inky colour, which shows conclusively that an oxidation or a formation of a dye-lake has taken place in the bath. It is known to everyone skilled in the art that such a dyebath will not produce a perfectly clean dye. In the new or cold mordant the bath will show all the way through a typical logwood colour, absolutely clear and transparent and not having a changed shade due to any oxidation. This fact explains the superiority of the colour produced by the Amend mordant.

It is, moreover, easily understood, that as there is no loss by precipitation or oxidation, the amount of colouring matter used with the new mordant must be considerably less than with any of the hot mordants. This fact has been ascertained in a long run in many of the dye-houses, the actual saving having been from 15 to 30 per cent. in logwood and logwood extracts. The hot mordant has been shown to produce a loss in colouring matter where the reactions are clearly visible in the result, as in the case of logwood. But the same takes place in case of alizarines and other mordant combining colours, where the reactions cannot be as easily followed by actual observation, but the loss is shown by the saving of the colouring matter in the new Amend mordanting process.

Another proof of the superiority of the colours produced by the new Amend mordant, is a comparative exposure to air, light, and moisture of samples dyed with equal percentages of dyestuffs by the new and old mordants. One will readily notice the much greater resistance of the colours produced by the Amend mordant, as compared with those by the old mordants. The different alizarine blues, for instance, show a characteristic bearing towards the action of direct sunlight. It is well known that the alizarine blues fade to a greyish shade, whereas indigo fades simply to a different shade in blue. Alizarin Blues dyed by the Amend mordant fade also, but instead of the grey shade produced by the old mordants, they, like indigo, fade to a different shade of blue.

A simple explanation of these reactions can easily be found, bearing in mind that any one of the old mordants contains chromic acid or acid salts of chromium, whereas the Amend mordant is free from these objectionable compounds; we have already demonstrated the destructive action of chromic acid and chromic salts in the dyebath, and in presence of moisture and light they continue their ruinous action on the colour as well as on the fibre. The correctness of these assertions is evident, inasmuch as every practical dyer admits that colours produced on heavily mordanted material will not stand the action of light and air, as well as the same colour would on a less heavily mordanted fibre; this plainly shows that the more heavily mordanted the material is by the old boiling method, it contains proportionately more chromic acid or its salts; whereas, in the Amend method, no matter how heavily mordanted the material might be, there is no possibility of these undesirable compounds being present.

We think therefore, that the saving of steam, the saving in colouring matters and wool weight, and the improvement of stock and in colours, as before shown, will appear favourably to anyone, and will be convincing of the advantages to be obtained by the use of the Amend process.

## DISCUSSION.

Dr. H. SCHWEITZER stated that he had seen, especially in Germany, very careful trials made with the new process, and it was an unqualified success, especially in regard to the saving of dyestuffs and to the preservation of the textile fibre.

Mr. ALAN A. CLAFIN asked Dr. Amend if, in the whole process of mordanting, the subsequent dyeing would not be conducted in a hot bath just the same as with the ordinary mordant. The use of this new process of chrome mordanting brought up a subject which he had investigated as well as he could with his limited opportunities, and he had the testimony of the dyehouses as corroborative evidence as to the best results to be obtained on a chrome mordant. On very many colours dyers preferred to use assistants which had no reducing power. On some of the new chrome blacks—for instance, the so-called Alizarin Blacks—the dyestuff producers recommend oxalic acid. Dyers frequently used bisulphate of soda, and from the results of the best textile chemists in the United States it seemed to be shown that a completely reduced chrome mordant was not often required. Similar results had also been found in the case of lactic acid. By the use of lactic acid with chrome, more complete and quicker reduction was obtained if the bichromate were first decomposed by sulphuric acid. Yet that process had not been adopted generally in the dyehouses for various reasons, such as unevenness in the dyeing, resulting from a too quick deposition of chrome, and the complicated nature of the process. If the lowest reduction of the chrome gave the best result, the adaptability of the new process was mainly a question of manipulation. He would like to see demonstrated whether the lowest oxide of chrome would give the best results on all colours, or whether it depended on the colour. He thought such experiments had been tried before, and that the testimony of the mill people had been the other way, but he was not certain that the results had been fully corroborated. Dr. Amend assumed that lactic acid could go on to the wool directly without change, whereas in the boiling bath with bichromate the lactic acid was decomposed and could not remain on the wool as an acid. In the cold process lactic acid might be found on the wool in an undecomposed state.

Dr. O. P. AMEND, in answer to Mr. Clafin, replied that as a matter of course it would. It had to be heated to a certain point before the colours could combine with the mordant, but it would take a lower temperature and less time; that was to say, one could develop logwood colour in 20 to 30 minutes at a temperature of 92 to 95 °C. That was not actual boiling. The boiling mordants, being of an acid nature, always developed a hard fibre, kinked and harshened it, and there was always a loss in weight. The unevenness in the dyeing was always due to some trace of acid on the fibre. If one took a large piece, say 100 yards, they would have spots or streaks. If they cut out these spots or streaks and compare them with other parts more evenly dyed, they would find they were due to the destructive action of some chromic acid or a chromic acid salt, or else some acid left on that part of the material. Another thing which demonstrated the effect of chromic acid or any other acid, in any form, on the fibre, was by exposing the so-produced colour to the action of sunlight and air. It was under such conditions that its oxidising and destructive action kept going on. In case of Logwood Black, it would turn a beautiful green. If every trace of the acid were removed and the washing is properly done, in the new process there would be no cause of unevenness, and the logwood black (a very handsome colour) would then stand any amount of sunlight. It had been demonstrated practically at Dobson's, in Philadelphia. They had dyed a large quantity of black, and found the results absolutely even. He was sorry he had not the samples to show to the members of the section, but that he would send them if they wished. Chrome oxide hydrate combined with the dyestuff as a base would with an acid; and, if there were no trace of sulphuric, chromic, or any other acid on the wool, a destructive action would not take place. Indigo bottomed wool combined with the chromic acid directly, without any appreciable change taking place; whereas there would be a

change in lactic or any other boiling acid mordant, that is to say, about 50 per cent. of the indigo would be lost. This pretty stable compound was actually oxidised by the boiling mordant. In the new mordant there was scarcely a perceptible loss of indigo.

## THE NEW GOVERNMENT LABORATORY.

THE new Government Laboratory, which has been two years in course of erection, was formally opened on October 1st. It is situated in Clement's Inn Passage, adjoining King's College Hospital, on a site covering 7,000 square feet. It is a plain red-brick building, with bands and corners of Portland stone, and has the advantage of being lighted on three sides. It consists of three floors and a sub-basement, and stands in an area, the surrounding wall of which is faced with white glazed bricks.

The main entrance, fronting Clement's Inn, leads directly to a central corridor on the ground floor. The corridor runs the length of the building, and communicates by staircases at each end with the other floors. All the internal walls, with exception of certain offices used as sitting-rooms, are faced with glazed bricks—white above, with border and tinted dado below; while the floors of the rooms are of pitch-pine "parqueterie," or of granolithic pavement.

The ground floor contains the private offices of the principal and deputy-principal, the reference library, the waiting-room, the research laboratory (a room 34 ft. long by 17 ft. wide), the Crown contracts laboratories—a set of three rooms, communicating with each other by arched openings, and having a total length of 69 ft. by 17 ft.—and the reference sample laboratory, 28 ft. by 20 ft.

The basement is similar in design to the ground floor, and has a central corridor running throughout its length. The boiler house, with engineer's workshop, various store-rooms for glass, chemicals, stationery, &c., and a receiving room for goods, occupy the further end of this floor, the remaining portion being taken up by laboratories for mechanical work, water analysis, and bacteriological work, the standardising of the instruments and apparatus required in the laboratory, the examination of hydrometers and saccharometers used in the Revenue Service, and the examination of the chemicals and the preparation of the solutions in use.

In the area—roofed in at this place with Hayward's lights—is a Hall's carbonic anhydride evaporating and condensing engine, the evaporation of the liquid carbonic anhydride being employed to cool a strong "brine" or calcium chloride solution. The cooled brine is used for making ice, for lowering the temperature of the water used in the main laboratory, and for circulating in the tanks in the cold-storage room.

The first floor of the building differs in design from the lower floors. The greater portion is occupied by the main distillation laboratory—a large room, 49 ft. by 43 ft., lighted by lofty windows and a dormer lantern roof. Opening on to a short corridor leading from this room to the main staircase are the two tobacco laboratories, and two rooms for the superintending analysts. Above these, on the second floor, are two laboratories, typewriter's office, and a museum. A flat roof, reached by a spiral staircase, covers this part of the building, and may be used for operations requiring to be done in the open air.

On the other section of the second floor, at the opposite end of the main laboratory, are photographic rooms and two laboratories, while the roof here carries the water-storage tanks.

A hydraulic lift communicates between the basement and the various floors.

The building is lighted throughout by electricity supplied from the public mains.

The pipes throughout the laboratories are easy of access, and are painted in different colours to indicate their purpose. In the basement the main supplies are carried below the ceiling of the corridor, and are visible throughout their length. On the first floor, in the main laboratory, a channel 5 ft. square, running beneath the central gangway, is cut off from the corridor below, and utilised for the conveyance of the gas, water, and steam-pipes. The service to the

benches is carried in a space behind the bench-cupboards, which have loosely-fitting backs to give access to these pipes.

With the exception of the rooms used for offices, where Teale's slow-combustion stoves are fitted, the building is heated by steam circulating through iron radiators standing in the corridors and on the floor of the various laboratories. Beneath the radiators are channels covered with slate slabs, and communicating directly with the outer air. In the main laboratory these ducts, carrying the fresh air, open into the central channel beneath the gangway along which the steam pipes are carried, the heated fresh air passing into the room through an iron grating. Along the base of the dormer lantern roof is fixed a copper steam-pipe for preventing a down draught.

The main ventilating system is worked by a fan situated in the basement. Leading from the top corners of the main laboratory down to the basement, and opening by gratings in the rooms through which they pass, are four air-shafts, which connect by oblique passages with a main duct, 7 ft. square, running underneath the basement corridor. The flues in the various evaporating and fume cupboards, with one exception, also lead downwards to the same main channel. The entire system is exhausted by the fan, the vitiated air being driven up the shaft surrounding the boiler flue. The fumes from the cupboard in which sulphuretted hydrogen is generated, pass away by means of a shaft entering directly the boiler flue.

There are three distinct water systems. High-pressure water is conveyed directly to the laboratories by branches from the New River Company's main, and is available for working filter pumps and doing other mechanical work. The water used in this way does not pass to the drain, but is conveyed to a clean waste reservoir below the basement floor. The New River Company's service is also connected with tanks on the roof for furnishing the ordinary bench supply to the various laboratories. This water, however, if simply used for condensing purposes, is received into a pipe, which conveys it to the clean waste cistern. The service to the benches in the main laboratory is from a special insulated tank of 1,000 galls., supplied with water cooled by the brine from the refrigerator. After passing through the condensers this "cooled" water also flows to the clean waste, serving to reduce the temperature of the general supply. The contents of the clean waste reservoir are pumped up to the storage tank on the roof; the boiler feed-water is a separate supply.

Reduced steam from the boiler is laid on to the various laboratories for heating and drying purposes, and for furnishing distilled water. The steam evaporating cupboards are constructed of crown glass in oak framing. The bottom is of slate, with an oak-faced projection or ledge in front, 6 ins. wide. The roof slopes from the front to just above the downward opening of the draught flues in the wall at the back. The doors slide up and down with balance-weights, and are prevented from shutting close down by india-rubber buffers. Underneath a bevelled hole in the slate slab is fixed a conical copper vessel. A removable porcelain collar, rising 3 ins. above the slate, fits in the hole, and carries a disk, 12 ins. in diameter, made of a steel plate thickly coated with "woodite," a material which has been found to be little attacked by steam, acid, or alkali. The disks are perforated with different sized holes. The pan is connected with two pipes; one of these, the steam supply, is opened by a valve when the bath is required; the other, fixed slightly below the steam pipe, carries away any accumulation of water from the condensation of the steam to a glass-faced indicator box, containing an overflow pipe at the same level as the outflow from the copper pan. This box, being connected with the water supply, serves to provide a constant level of water in the pan when the steam from the boiler not being available, the vessel is heated by gas—a Bunsen burner being fixed below for this purpose. In those cases where the slate bottom carries more than one pan, the cupboard is divided by glass partitions into compartments, each separately connected with the flues.

Cupboards similar to these, but fitted with a gas supply in place of the steam arrangements, are also erected for conducting operations requiring a higher temperature or

evolving noxious vapours. The metal connections of the gas are outside the cupboard.

Distilled water is obtained in the various laboratories by condensing the excess steam used for heating the sand-bath and drying oven, the whole forming a connected system. Fixed to the wall, at a height of 5 ft. from the floor, is the drying oven, made of stout copper, and protected externally with asbestos and lagging of oak. The bronze front has plate-glass panels. A regulated current of air may be introduced, but the apertures are so arranged that the air passes through a considerable portion of the heated covering before entering the bath. On opening a valve, steam is admitted to the surrounding jacket of the oven, and, after circulating there, is carried by means of a copper pipe to a worm of block tin contained in an iron drum provided with a supply of cold water. The condensed water runs into a large earthenware jar fitted with glass tap. An overflow pipe of stout glass leads from the bottom of the jar, and at the same time indicates the level of the water within.

Beneath the steam oven stands a small press, the top of which consists of a tin-lined copper box. This box is heated by the steam supply, and also receives the hot water obtained by the partial condensation of the steam in and around the drying apparatus. It is provided with a tap and furnishes hot distilled water. The box has an overflow pipe communicating with a steam trap, and returns all surplus water to the boiler. The top of this small hot-water cistern is tray-shaped, and is used as a sand bath, while in the warm cupboard beneath, rails are arranged for the drying of towels, &c.

The working benches in all the rooms except the main laboratory are arranged along the walls beneath the windows, and consist of a mahogany top overhanging by 3 ins. a row of drawers and cupboards below, the whole being raised from the floor to allow of recessed toe-space. The gas supply is carried along the front of the bench beneath the projecting ledge, where are also the taps on the branch pipes, which pass under the top to the nozzle at the back of the bench. Between each two workers is an oblong porcelain basin with water standard, fitted with a Kelvin tap delivering water to the basin, and with branch pipes for drawing off water for condensers. A Fischer metal filter pump with indicator gauge, and connected with the high-pressure water system, is fixed on the bench, and also a pipe for conveying away the clean waste water from condensers, &c. The waste water from the basin passes into a V-shaped wooden trough, lead lined and coated with pitch. This trough, after receiving the waste from other benches, empties into a funnel, also pitched; a continuing pipe leads to the drains outside the building.

The reagent shelves are of stout plate glass resting upon gun-metal brackets, the ledge of the bracket being faced with a strip of corrugated rubber.

In the main laboratory are eight blocks of benches arranged in two rows on either side of a wide central gangway, to which the benches run transversely. Each block is divided into four working benches, a white-ware basin being at each end of the block for the joint use of the two men working opposite to each other. Down the centre of the block, and raised a foot above the mahogany top, is a pewter-covered shelf, beneath which is the service pipe of cool water with which this room is supplied for distillation work. The electric light wires are carried beneath the shelf to stand-lamps at each end, and buttons are also fixed in the circuit for the attachment of electric motors. Each block is connected independently with the main supply and return pipes, and may be cut off without affecting the other benches in the room. A shallow pewter-lined tray with draining hole rests on the edge of the basin, for holding the ice-bath and flasks, and when not in use slides into recess below the bench top. The cupboards and drawers are similar to those in the other rooms, being of oak wainscot, and the pipes are conveyed in a space between the backs of the benches.

A dark room for polarimetric work opens from this laboratory, which is also provided with a cold-storage chamber, cooled by a circulatory system of brine from the refrigerator.

The standard solutions are kept in small oaken cabinets with glass-panelled doors. The top of the cabinet is of

crown glass, and carries a light framework of brass, with small spring clips, for holding the burettes. A side tube, with stop-cock, at the bottom of burette is connected by piece of rubber tubing passing through a hole in glass top with the solution bottle contained on the shelf opposite the glass door of the cabinet, the burette being filled by suction. After a titration the liquid is run back into the storage bottle, which is protected by a soda-lime tube and stop-cock. A reserve stock of solution is stored at the bottom of the cabinet.

One of the tobacco laboratories is constructed of fire-proof materials, and contains furnaces and drying ovens. The drying ovens are arranged so that the steam may pass through one or more as required. They are connected with a self-filling boiler heated by gas, arranged so as to maintain a supply of steam over night.

There are three large muffle furnaces, standing on a wide stone hearth, beneath a capacious flue, and a specially constructed piece of apparatus for charring vegetable substances. This consists of 160 small Bunsen burners arranged in five double rows and regulated in fours from the front. A nickel-plated grid, for holding the dishes, is fixed above the whole.

In the different laboratories are arrangements adapted for the work of the particular department.

For melting butter and other fats, there is an oven with sliding glass doors, and beneath it an open copper bath in which to carry on the filtration—both being heated by steam as required. For combustion work there is a stone table with glass hood, and connected with draught flue; and a Muencke trompe connected with the high-pressure water supply is attached to the wall above the blow-pipe table.

The laboratory has been built, under the superintendence of the Office of Works Department, from designs furnished by Dr. T. E. Thorpe, F.R.S.

## Obituary.

### SIR HENRY DOULTON,

MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

SIR HENRY DOULTON died on Nov. 17, at his residence in Queen's Gate Gardens, South Kensington. Death was due to an affection of the heart, with which he was seized only a few days ago. Sir Henry, who was the second son of Mr. John Doulton, of Lambeth, was born in 1820, and educated at University College School. At the age of 15 he began his technical training as a potter, and in 1870 commenced the manufacture of art pottery and Doulton ware, and ultimately became the senior partner in the firm of Doulton and Sons, which has establishments at Lambeth, Smethwick, St. Helens, Burslem, and Paisley. He was knighted in 1887, having already been created a Chevalier of the Legion of Honour. The Albert Medal of the Society of Arts was specially conferred on him at Lambeth by the Prince of Wales. He had also received 105 diplomas of honour and gold medals, and 102 silver medals. The speciality of the work of Messrs. Doulton was terra cotta, but it was not confined thereto. Sir Henry greatly stimulated the art education of Lambeth, and it was his experienced eye which detected the artistic work of Mr. George Tinworth, all whose beautiful bas reliefs have been produced at Lambeth, and who has continued throughout his life in the service of his first patron. Sir Henry provided the best accommodation for his workpeople, who were considered in every way.

In the year 1889, when the Annual Meeting of the Society was held in London, Sir Henry Doulton entertained the members to luncheon at his Art Pottery, in Lambeth, and gave a most interesting demonstration. (See this Journal, 1889, 510—511.)

He married, in 1849, Miss Kennaby, and was left a widower in 1888. During the whole of his business life he identified himself with most of the philanthropic and charitable works started for the benefit of South London.

## I.—PLANT, APPARATUS, AND MACHINERY.

### PATENTS.

*Coffey's Distilling Apparatus, Impts. in the Packing of the Tubes in the Rectifiers of.* R. M. McDougall, Glasgow. Eng. Pat. 24,405, Nov. 2, 1896.

A FERRULE is soldered on to the still tube, where it passes through the frame of the rectifier, and is screwed externally to receive one or more screw collars or glands, by means of which the packing material is compressed into recesses in the frame surrounding the tube; this represents the claim. A gland may be provided both on the exterior and interior of the frame, or on the exterior only.—R. A.

*Filter Presses [Potter's Slip, &c.], Impts. in.* J. Critchlow and T. Shore, both of Stoke-on-Trent, Stafford. Eng. Pat. 26,112, Nov. 19, 1896.

THE invention relates to the class of filter press described in Eng. Pat. 17,924 of 1893. Instead of mounting the filter trays on rollers, as in the prior specification, they are provided with shafts or stud-carrying rollers, which run on racks on the side frames of the machine. The trays are brought together by rotating the shafts, &c. by means of suitable handles, and the required pressure is applied to the end tray by means of a screw, which is tightened up first by hand and then by worm gearing.—R. A.

*Absorbing Gases in Liquids, An Improved Absorption Apparatus for.* H. Ritzel, Leipzig-Plagwitz, Germany. Eng. Pat. 18,578, Aug. 10, 1897.

THE apparatus comprises a vessel through which the gas is slowly passed, and a number of sets of spraying nozzles arranged one set above the other within the vessel. The nozzles of each set are directed tangentially so as to produce a rotation of the sprayed liquid and the gas, the nozzles of adjacent sets being set in opposite directions to ensure a thorough mixture of the gas with the liquid. To facilitate the removal or insertion, or the opening or closing, of any of the nozzles, they are attached by means of connecting pipes and couplings with a multiple-way cock which controls the liquid supply to each nozzle.—R. A.

\* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to C. N. Dalton, Esq., Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

## II.—FUEL, GAS, AND LIGHT.

*Coal Ash, Relation between the Composition and Fusibility of.* E. Prost. Bull. Assoc. Belge des Chim. 11, [1], 119—126.

TAKING as a basis, on the one hand, the results of determinations of composition and fusibility of 29 samples of Belgian coals, and on the other, the formula established by Bischof for the fusibility of clays, the author finds that the quotient obtained by dividing the amount of oxygen in the silica by that in the alumina of the ash, and the result by the oxygen of the other bases present ( $\text{Fe}_2\text{O}_3$ ,  $\text{CaO}$ ,  $\text{MgO}$ ), affords an indication of the relative fusibility of the ash. The result is, however, dependent on the percentage of the last-named bases, and especially of iron, since, as this percentage increases, the fusibility decreases, in consequence of the fusible silicates becoming embedded in the excess of bases and the whole partaking more of the refractory character of the latter.

Combining the above considerations, the practical result obtained is, that when the said quotient amounts to or exceeds 2.25, in presence of not over 7 per cent. of iron, the fusing point of a coal will be about  $1,500^\circ\text{C}$ .; i.e., the ash is considered as refractory. On the other hand, when the value of the quotient ranges between 1.6 and 2.25 (or even higher), but the iron exceeds 7 per cent. to any appreciable extent, then the ash is moderately fusible ( $1,350^\circ$  to  $1,500^\circ\text{C}$ ). And finally, all samples of ash yielding a quotient inferior to 1.6 will be found fusible at about  $1,350^\circ\text{C}$ .—C. S.

*Coke-Oven Gases, Utilising.* Report of the Commissioner of Labour and Inspector of Mines, Tennessee, 1896. Eng. and Mining J. 1897, 64, [13], 369.

IS the utilisation of coke-oven gases for the heating of boilers, the following points should be observed:—The flue for conducting the gases from the ovens to the boilers should be built of the best material, and of ample size, and should be so constructed as to be without a descending grade. The boiler flues and stack should be of such size that the gas may meet with as little friction as possible in its passage. The ovens should be promptly and systematically drawn and charged, and should be kept covered when in use. The flue and boiler setting should be kept air-tight. —A. S.

*Water-Gas, Progress in the Production and Use of (Dellwik's Generator.)* H. Dicke. J. für Gasbeleucht. 1897, 40, 665—669.

WATER-GAS is made for 15 minutes, and producer gas ( $\text{CO} + \text{N}$ ) for 45 minutes per hour, in generators of the usual type; but in Dellwik generators, water-gas is made for 45 minutes and spent gases ( $\text{CO}_2 + \text{N}$ ) for 15 minutes per hour. 18 kilos. of steam are decomposed to form water-gas by 12 kilos. of carbon by the aid of 28,760 calories, derived from the action of the air-blast on the fuel. 12 kilos. of carbon under the air-blast, afford 14,905 available calories by the old, and 61,598 available calories by the Dellwik process. The Dellwik process therefore, it is said, makes available for water-gas production about four times as much heat as the old process does. The Dellwik generators yield no producer gas, and give at least twice the production, it is stated, of the old water-gas generators: they are therefore specially adapted, it is claimed, for the supply of towns with water-gas for lighting by incandescence. Water-gas, odourised by mercaptan or carbhydramine, is the cheapest and best gas for such a purpose. It may, however, in some cases be carburetted by passage through a retort in which oil is being carbonised. The heat of the retort is easily controlled, and the supply of either water-gas or oil to the retort can be regulated merely by turning taps. A more uniform carburetted water-gas can be produced by this means than by the generators, with large regenerative carburetting chambers attached, which are in use in America and England. Where an increased make of gas is required in existing

gasworks of limited area, water-gas may be introduced and mixed with the coal-gas. If 1 kilo. of coke affords only 1.6 cb. m. of water-gas, the surplus coke from the coal-gas retorts, after firing them, will suffice to make so much water-gas that the total volume of the mixed gases would be 2.6 times that of the coal-gas. A mixed gas, consisting of coal-gas and as much water-gas as that coke which is not used as fuel will afford, if burnt at the rate of 200 litres per hour, gives a light of 100 Hefner units. Coal-gas similarly burnt in incandescent burners at the rate of 110 litres per hour, yields 60 Hefner units. Given a works supplying 3,600,000 cb. m. of coal-gas per annum, and obtaining 12,823 Pfennige per cb. m., the same amount of light will be secured from 4,083,000 cb. m. of mixed gas, and the equivalent price will be 11 Pf. per cb. m. It is computed on this basis and with coal at M. 137 per 10,000 kilos., that the net profit per cb. m. will be 3.848 Pf. for coal-gas and 5.082 Pf. for the mixed gas. Also, that for a given calorific value, the holder cost of the mixed gas will be about 40 per cent. less than that of coal-gas.

The latest Dellwik generator (this Journal, 1897, 431 and 525) yields, however, 2.4 to 2.5 cb. m. of water-gas per kilo. of coke. In one trial, in which a  $1\frac{3}{4}$  minutes' blast alternated with a 12 minutes' make, and 100 cb. m. were made per hour, 2.4 cb. m. of water-gas were obtained per kilo. of smithy coke from the Consolidation pits (Ruhr district). The spent blast gases contained, on an average, 18.2 per cent. of carbonic acid, and 100 vols. of the water-gas consisted of:—Carbonic acid, 3.6; carbonic oxide, 40.4; hydrogen, 51; nitrogen, about 4.5; and marsh-gas, about 0.5. There was about 92 per cent. of carbon in the coke; hence about 2.6 cb. m. of gas were obtained per kilo. of carbon. Therefore 2.5 cb. m. may be expected with certainty; and, at a calorific value of 2,600 per cb. m., and with carbon yielding 8,080 calories per kilo., about 81 per cent. of the calorific power of the carbon will be found in the water-gas. In another trial, with  $1\frac{1}{4}$  minutes' blast and 7 minutes' make, and a production of 100 cb. m. per hour, 2.55 cb. m. of gas were obtained per kilo. of Essen gas-coke. The larger make per kilo. appears to be due to the greater porosity and more extensive surface of the gas-coke. In a 27-hour trial, 120 cb. m. per hour and 2.58 cb. m. per kilo. of Charlottenburg gas-coke were secured. The injuries caused to incandescent mantles by deposition of iron from traces of iron carbide in water-gas have been exaggerated. Water-gas from which iron has not been separated has given satisfactory results at Radkersburg, where it has served as the town supply for  $1\frac{1}{2}$  years.

—J. A. B.

*Calcium Carbide, Impurities in Commercial.* H. Le Chatelier. Bull. Soc. Chim. 1897, 17, 793—794.

BESIDES calcium and carbon there are present in commercial calcium carbide, silicon and iron. By decomposing by water and then by acid, and floating the residue in methylene iodide, the whole of the iron is found at the bottom as silicide. If the calcium be in excess of the carbon, the remaining silicon appears as calcium silicide; but if the carbon be in excess, carbon silicide is formed. Thus the determining affinities are those of iron for silicon and of carbon for calcium. There seem to be two silicides of calcium—one attacked by hydrochloric acid, but not by nitric; the other easily attacked by nitric or acetic acid, and giving with hydrochloric acid an insoluble white residue in place of the yellow one (the "*Silicone*" of Wöhler) which the other leaves. The attack of calcium silicide by acid leaves a mixture of these residues, analyses of which vary between the formulae  $\text{Si}_2\text{O}_3\text{H}_4$  and  $\text{Si}_2\text{O}_3\text{H}_2$ .—J. T. D.

*Acetylene, Poisonous Action of.* U. Mosso and F. Ottolenghi. Ann. di Chim. e di Farmacol. 25, 163; Chem. Zeit. Rep. 21, [59], 158.

See under XVIII. B., page 930.

*Total Ammonia in Gas Liquor, Estimation of.* E. Donath and K. Pollak. Zeits. angew. Chem. 1897, 555.

See under XXIII., page 936.

## PATENTS.

**Incandescence Bodies for Gas and other Burners, Impts. in.** A. Kiesewalter, Limburg-on-the-Lahn, Germany. Eng. Pat. 20,221, Sept. 2, 1897.

THE novelty claimed is "the preparation of incandescence lighting mass" by fusing in a closed vessel a mixture of pure oxides of barium and magnesium together with a small quantity of antimony oxide or bismuth oxide. The glassy mass is pulverised, dissolved in acid, and the solution used for impregnating organic materials. If it be desired to avoid a yellow or reddish-yellow tint of light, in place of silica or zirconia, lime or thoria may be used, either each separately, or both intermixed, whereby a bluish or yellowish light is obtained.—H. B.

**Incandescent Bodies, An Improved Solution or Fluid for Impregnating.** L. Freudenthal, Berlin. Eng. Pat. 20,225, Sept. 2, 1897.

THORIUM oxalate is converted "by suitable treatment" into nitrate, which is dissolved in water, and "a small quantity of the chlorides of other metals is added." No specific example is given, but "the choice of the metal chloride to be added is made according to the actual requirements as regards (for instance) strength of light, colour of light, permanency of the light, or durability of the incandescent body."—H. B.

**Incandescent Oil Burner, Impts. in or relating to Burning Liquid Hydrocarbons in conjunction with an Incandescent Hood or Mantle to produce an.** J. L. Waldapfel, Cologne. Eng. Pat. 20,713, Sept. 18, 1896.

THE arrangement of the lamp is such that "that part of the apparatus in which the gases are mixed and filtered, is built into the reservoir for the liquid." The initial gas pressure is obtained by applying an auxiliary flame directly to the bottom of the reservoir containing the liquid to be vaporised. Within the reservoir, and fastened to its upper cover, is a cylindrical upright vessel, into which the gases liberated from the heated liquid hydrocarbons flow, and are made to pursue a tortuous up-and-down course through a series of pipes and chambers within the vessel. On their way the gases have to pass through a filter or mixer, consisting of a number of small layers of felt with intermediate wire gauze, and finally they issue into a small gas-holding chamber at the top of the lamp, through a tube with a downwardly directed mouth. The gasholder is surmounted with a burner and mantle as usual. From the bottom of the internal cylindrical vessel passes a small pipe to the outside of the lamp, fitted with a valve-cock, and terminating in a burner under the bottom of the reservoir. As soon as gas is generated, the auxiliary lamp is removed, the valve-cock is opened, and the gas issuing from the burner is ignited, so as to make the lamp act continuously.—H. B.

**Hydrocarbon Incandescent Lamps, Impts. in or connected with.** R. Haddan, Buckingham Street, W.C. From J. W. Allison, New York. Eng. Pat. 3,446, Feb. 9, 1897.

TO avoid the use of capillary tubes, the vaporiser consists of a straight tube of relatively large diameter, having at its upper end a dismountable nozzle and orifice, which are connected with a device wherein the gas mixes with air, which is sucked in by the rush of gas. The rate of flow of the gas through the orifice is regulated by a needle which extends throughout the length of the vaporising tube, and is actuated by a lever at its base. The admission of petroleum to the vaporising tube is controlled by means of a lever provided with an eccentric, operating upon a diaphragm which carries a valve. "The two essential elements" are the vaporiser and air-mixing chamber, and they may be combined for the production of incandescence by means of mantles, in various ways. There are twelve claims for various combinations of parts.—H. B.

**Incandescence Bodies for Heating Purposes, Impts. in and relating to.** A. Quentin, Brussels. Eng. Pat. 23,006, Oct. 16, 1896.

A "HEATING mass" is to be prepared which will become incandescent on contact with a mixture of air and certain combustible gases. The heating surfaces of suitable appa-

atus (boilers, &c.) are to be coated with this preparation. After the preliminary heating of a part of the coating, the gaseous mixture is to be turned on, causing incandescence over the whole surface; ordinary fuel is to be dispensed with. To obtain such a "heating mass," a mixture of kaolin and powdered pumice is treated with a solution of a suitable metallic salt (such as platinum chloride), and on calcination a porous mass containing metallic platinum is obtained. This process of manufacture is claimed, and there is a general claim for "a heat-giving mass for a heating surface" of the nature above described.—H. B.

**Incandescent Lighting or of Heating by Acetylene, Impts. in Apparatus for applying Acetylene Gas to the Purpose of.** L. Edwards, Chancery Lane. From R. Therr, Paris. Eng. Pat. 26,041, Nov. 18, 1896.

ACETYLENE gas is to be burned in a form of Bunsen burner, the flame raising a mantle of the well-known kind to incandescence. The air is admitted to mix with the gas in such proportion that the flame is smokeless and forms a small blue-green cone surrounded by a reddish outer one. The burner claimed differs from the ordinary Bunsen burner (1) by having the upper end of the burner-tube fitted with a conical or any other burner-mouth the sectional area of which is less than that of the burner-tube; (2) by having at the lower end of the burner-tube a tubular acetylene inlet jet which is movable within the burner-tube, so that the latter can be lengthened or shortened; and (3) by being fitted internally with a cylindrical piece which is pierced with a hole which allows the mixture of gas and air to be drawn in more quickly. The application of mantles for producing incandescence by the combustion of acetylene is claimed.—H. B.

**Mantles or Incandescing Bodies "Self-Lighting" for Incandescent Gas Lamps, Impts. in the Manufacture of.** J. E. Duke, West Dulwich. Eng. Pat. 26,618, Nov. 24, 1896.

REFERENCE is made to Eng. Pat. 969 of 1895, which described an automatic gas igniter consisting of a block of meerschaum containing in its pores platinum black. According to the present invention a very fine line of highly concentrated platinum chloride solution is painted downwards from the top of the mantle, before the organic fibre is burnt out. After burning out, the line of metallic platinum left is streaked over with a solution of calcium carbonate (prepared from calcium hydrate and carbonic acid water) containing in 20,000 parts of solution 1 part of platinum bichloride. The latter is reduced to the metallic state on heating the mantle in a gas flame. To the mantle and in contact with the upper end of the line of platinum, is fitted a gas-igniting meerschaum block, such as above mentioned. On turning on the gas, the igniting block and then the platinum line become red hot, communicating the heat to the minute quantity of platinum mixed with the lime: the lime thereupon becomes incandescent and ignites the gas.—H. B.

**Incandescence Mantles, Impts. in.** A. Kiesewalter, Limburg-on-the-Lahn, Germany. Eng. Pat. 15,963, July 5, 1897.

THE patentee claims a process of preparing mantles by fusing "the oxides suitable for incandescence purposes" along with silicic acid and caustic potash or caustic soda. The glassy product is "dissolved in water" and organic fabrics are impregnated with the solution. "The incandescence material is then precipitated in the said fabric by means of a mixture of suitable acids and reagents, and the residual salts which are soluble in water, are washed out of the fabric." For instance, in using an "alkaline calcium water-glass solution," the calcium compound is to be "precipitated" within the fibre by means of sulphuric acid, or a mixture of oxalic and hydrochloric acids.—H. B.

**Fuel, Impts. in or relating to the Manufacture of.** P. R. de F. d'Hunty, Liverpool. Eng. Pat. 20,156, Sept. 11, 1896.

CHEAP or waste fibrous combustible materials, such as shavings, sawdust, peat, pine and fir cones, resinous bark,

refuse from cotton and linen mills, &c., are mixed with a mineral oil, ozokerite, naphthalene, an alkali, as caustic soda, and an oxidising compound, as sodium nitrate, chlorates, bichromates, &c., and the whole is heated to about 600–700° F.—R. S.

*Promoting the Combustion of Smoke or Inflammable Gases in Steam-Boiler and other Furnaces, New or Improved Means for.* H. Whitaker, Newent, Gloucestershire. Eng. Pat. 21,329, Sept. 26, 1896.

Bricks on the fire bars at the rear part, and at right angles thereto, are a number of parallel vertical metal plates, which become intensely hot, and between which a large supply of air from the ash-pit passes, to supply the desired quantity of heated air wherewith to consume the smoke or inflammable gases.—R. S.

*Treating Smoke for the Extraction of the Carbon and other Residual Products resulting from Imperfect Combustion, Impts. in the Mode, Means, and Apparatus for.* W. M. Ward, Handsworth. Eng. Pat. 262, Jan. 5, 1897.

This invention consists in interposing a washer or scrubber in the flue, the said scrubber being formed of a chamber wherein a horizontal shaft, carrying beaters or arms, is caused to revolve in such a manner as to force the smoke into and through a shallow layer of water. This chamber has a perforated cover, through which the smoke has to pass before reaching the chimney, and which is supplied with water from a perforated pipe.—R. S.

*Gas-Retort Settings, and Regenerator Furnaces for the same; Certain Impts. in the Construction of.* G. E. Stevenson, Claremont, Crumpsall, Manchester. Eng. Pat. 22,887, Oct. 15, 1896.

1st. The gas-producer arch and the side walls thereof are built forward of and through the front wall of the retort setting, and a firing hole is formed in this projecting part. The end wall of the producer is built separate from the front wall of the retort setting, so as to fill in the end of the arch between the side walls and to receive the fire-grate fittings.

2nd. The regenerator flues, both for air and for waste gases, are formed of vertical fire-clay tiles, each one the full depth of each flue, having curved sides, so that the flues become narrower at the top and bottom, and thereby afford a wider bearing surface for the fire-clay top and bottom covering tiles. The latter are either provided with a projecting lug, fitting between the edges of the vertical tiles, or are made flat, in which case thin slabs are used to fill in the same space.—R. S.

*Hydrocarbons, Apparatus for Vaporising; applicable to Engines worked by Gas, Petroleum, Alcohol, and the like.* E. Petréano, Paris. Eng. Pat. 23,270, Oct. 20, 1896.

The object of this invention is to prepare a homogeneous explosive mixture of hydrocarbons (or alcohol) and air, outside the engine cylinder, and to prevent the access to the latter of any of the liquid substances used.

This is effected by introducing the air and liquid to be vaporised into an annular vertical chamber surrounding and deriving heat from either the cylinder or the exhaust pipe therefrom, and containing a number of superimposed cones. These are fixed alternately to the outer and inner walls of the chamber, and thus constitute a series of baffles facilitating the production of a uniform mixture. The resulting gas passes into a bell or chamber, whence it is drawn by the stroke of the engine piston, whilst the unvaporised oil is drained off through a pipe in the bottom of the vaporising chamber.

By applying the same apparatus to the ordinary gas engine, it is claimed that in comparison with the usual method of mixing the gas and air in the engine cylinder, an instantaneous and more perfect combustion of gas, and therefore increased efficiency, is ensured. Moreover, the water jacket of the cylinder can be dispensed with, the entire heat due to the explosion being confined to the compression chamber; and the introduction of steam into the cylinder

to reduce the temperature of the explosion can be effected without risk of decomposition and the consequent corrosion of the cylinder.—C. S.

*Oil, Vaporising; Impts. in or connected with Apparatus for.* C. Crastin, London. Eng. Pat. 24,793, Nov. 5, 1896.

To prevent surplus oil entering or remaining in the vaporising chamber, the oil is allowed to fall from a sight-feed device on to a perforated disc situated below the air inlet, the mixture of air and vapour being drawn off through a lateral tube to the vaporising chamber, whilst the excess of oil runs down into a collecting vessel. The vaporising chamber consists of the annular space between two vertical concentric tubes, and is closed at both ends, except for the inlet pipe below and the outlet above, leading to the motor, &c. Heat is applied to the chamber by the flame of a lamp situated below the open end of the inner tube, and radiation is prevented by a case lined with insulating material.

—C. S.

*Gas [Oxygen, Carbonic Acid, &c.] Absorbing Apparatus for ascertaining the Quantity of a particular Gas in a Gaseous Mixture [Smoke Gas, &c.].* M. Arndt, Aachen, Germany. Eng. Pat. 25,762, Nov. 16, 1896.

See under XXIII., page 935.

*Regenerative Furnaces, Certain Impts. in or connected with.* J. W. Hall, Bilston. Eng. Pat. 26,937, Nov. 27, 1896.

This invention consists in providing the ordinary Siemens regenerative furnace having four regenerators, with two additional regenerators, which are so connected by means of valves of the usual kind, that the whole of the products of combustion, after leaving the usual pairs of regenerators on the exhaust side of the furnace, are passed through one of the additional regenerators, while the air passes through the other one before entering the usual air regenerators. These regenerators are reversed in the usual manner.

—R. S.

*Carbonizing, Charring, or Coking Combustible Substances, An Improved Process for.* A. Basch and H. Graepel, Budapest. Eng. Pat. 5698, March 3, 1897.

COMBUSTIBLE substances which heretofore have been found to be either entirely incapable of coking, or which could only be coked with difficulty (as for example Transylvanian Crown-coal), are mixed with products obtained from the distillation of tar. They can then be coked in a comparatively short time. In the above case, the addition of one-half per cent. of naphthalene enables the coking to take place at about 275° C.; but the temperature of distillation varies according to the nature of the fuel.—R. S.

*Bunsen Gas Burners, Impts. in.* H. Marshall, Edinburgh. Eng. Pat. 238, Jan. 5, 1897.

INSTEAD of the gas entering the mixing tube through a central nozzle, it is introduced through one or more apertures at the side, or through an annular slit with an upward inclination. The air tube is left open at the base, and may be closed when desired by a sliding cover working on a pivot.

—C. S.

*Blue Flame, Impts. in Apparatus for Generating a Vaporous or Gaseous Mixture from Hydrocarbon-containing Liquid and Water for the Production of.* F. Altmann, Berlin. Eng. Pat. 15,261, June 25, 1897.

In this lamp the water and the hydrocarbon liquid are contained in separate reservoirs, and are conveyed thence—either by capillary attraction or hydrostatic pressure—into vessels where they are vaporised by the heat from a flame below. The resulting gases ascend into a mixing chamber communicating direct with the main burner. The relative heat applied to the liquids may be regulated by altering the position of the heating flame. It is claimed for the invention that, the mixing chamber and burner being so close together, condensation of the vaporised substances is precluded.—C. S.

*Illuminating Gas, Carburetting; Impts. relating to, and to Apparatus therefor.* E. F. J. C. Bauweraerts, Brussels, Eng. Pat. 15,369, June 26, 1897.

THE inventor finds that the most suitable substances for mixing with acetylene and mixtures of the same with ordinary illuminating gas in order to produce a smokeless flame, are such volatile bodies containing carbon, hydrogen, and oxygen, as ethyl oxide, acetic acid, acetone, and the alcohols, preferably methyl alcohol. This latter also frees the gas from fatty and other impurities, the addition of a little sulphuric acid also ensuring the removal of hydrogen sulphide.

The apparatus for mixing and "enriching" the gases, consists of a funnel-shaped mixing chamber into which the gases are delivered, and which discharges them into a vessel below, where they pass over the surface of a layer of methyl alcohol and are thereby "enriched," in the sense that "the hydrogen of the methyl alcohol will increase the heat of combustion, and be aided by the oxygen, thus effecting the complete combustion of the carbon, and thereby increasing the luminosity of the flame." The scum of impurities floats on the alcohol, and is drained off through a suitable overflow pipe into a closed receptacle, whilst the gas is led through a main to the burners. The admission of acetylene to the mixing chamber (and thus its proportion there) is suitably regulated.—C. S.

*Petroleum Blue-Flame Burners for Incandescent Lighting and Heating Purposes, Impts. in.* M. Bernstein, Berlin. Eng. Pat. 17,927, July 30, 1897.

IN order to shorten the time requisite for gasifying the oil when the lamp is first lighted, and thereby to minimise the deposition of soot on the mantle, the inventor mounts above the wick a flame divider and a circular hollow chamber, wherein a portion of the air, ascending the space enclosed by the wick, is superheated and is delivered to the inner side of the flame. A supply of heated air to the outer side of the flame is secured by a perforated metal cylinder (of sheet metal) surrounding the flame, and also serving as a support for the incandescent mantle. A set of baffles is mounted in the central air space enclosed by the wick duct, in order to impart a whirling motion to the incoming air, and thus facilitate its mixture with the upper gases of combustion.—C. S.

*Gas suitable for Heating, Motive Power, or Lighting Purposes, by the aid of Volatile Hydrocarbons; Impts. in and relating to Apparatus for Producing.* W. P. Thompson, London. From A. Julien, Brussels. Eng. Pat. 18,005, July 31, 1897.

THE essential part of the apparatus is the mixing carburettor, a cylinder filled about one-third full with the carburetting liquid employed. The mixing is effected by the rotation of a number of perforated discs or paddles mounted on a shaft and partly covered with an absorbent material and sponges. Into this vessel the air to be enriched is forced from a compressor, either direct or *via* a gasholder containing some carburetting vapour, and is intimately and evenly mixed with vapour by the movement of the paddles.

For heating purposes, the discharge pipe of the carburettor may lead direct to the furnace and there be provided with a burner nozzle. It is also claimed that the apparatus will produce a superior explosive mixture for use in automotors, as well as an illuminating gas burning with a smokeless flame.—C. S.

*Acetylene Gas, Impts. in Apparatus for Generating.* W. J. Mackenzie, Glasgow. Eng. Pat. 23,752, Oct. 26, 1896.

A WATER-JACKETED bell linked to its containing tank, covers a carbide container to which a pipe with cock operated by the movements of the bell of the gasholder gives access to the water in the tank of the latter. A spring brake on the operating lever prevents the cock being entirely closed until the gasholder is nearly filled with the acetylene

generated. A device for automatically shutting off an exhausted generating apparatus and putting in action a fresh apparatus is described.—J. A. B.

*Acetylene, Impts. in Apparatus for Automatically Producing and Storing.* E. Chesnay, Dijon; L. Pélion, Dijon; and C. Berthoin, St. Etienne, France. Eng. Pat. 25,236, Nov. 10, 1896. (Under Internat. Convention.)

CARBIDE is fed into a vessel containing water, through a shoot to which it is supplied from a hopper by means of an Archimedeian screw, the rotation of which is controlled by the balance weight of a gasholder bell, into which the gas passes as generated. The screw is rotated by any mechanical motor under the control of the balance weight.—J. A. B.

*Acetylene Gas, Improved Apparatus for the Production of.* A. Fournier, Paris. Eng. Pat. 25,488, Nov. 12, 1896.

A HOPPER for carbide is attached to the crown of the bell of a gasholder. The lower constricted end of the hopper is closed by a conical valve, which opens when an attached rod strikes the base of the holder, owing to the sinking of the bell, and closes when the bell again rises. When the valve is open, carbide passes from the hopper into the water in the tank of the holder and generates acetylene.—J. A. B.

*Acetylene Gas, Impts. in and connected with Apparatus for the Production and Utilisation of.* J. Vaughan-Sherrin, London. Eng. Pat. 26,897, Nov. 26, 1896.

A FIXED or rotating water tank is connected with a number of carbide containers which are put in communication with it in turn by means of taps operated automatically or at a signal given by the gasholder when collapsed to a certain degree.—J. A. B.

*Acetylene Gas, Impts. in or connected with Apparatus for Producing.* W. P. Thompson, Liverpool. From L. L. H. Gérard, Paris. Eng. Pat. 29,188, Dec. 19, 1896.

THE orifice at the bottom of a carbide receptacle placed above a water reservoir is opened and shut by valves on a rod, moved by a diaphragm exposed on one side to the pressure of the acetylene generated, and on the other to the atmospheric pressure. When the valve is open, crushed carbide falls into the water. Or the diaphragm may, by means of a pawl and ratchet, rotate a recessed drum, which discharges the carbide into the water.—J. A. B.

*Acetylene, Impts. in Apparatus for the Manufacture of.* P. De Résener and H. Luchaire, both of Paris. Eng. Pat. 29,320, Dec. 21, 1896. (Under Internat. Convention.)

IMPROVEMENTS on the apparatus claimed under Eng. Pat. 24,440, Nov. 2, 1896 (this Journal, 1897, 790), are described. They consist of a regulator to proportion the flow of water to the carbide receivers to the consumption of gas; and a pipe with cock to cause the water to flow to a second receiver when the first is exhausted.—J. A. B.

*Acetylene, An Improved Apparatus for Manufacturing.* P. de Résener, Paris. Eng. Pat. 30,037, Dec. 30, 1896.

A CARBIDE receiver is placed above a water tank, the cover of which contains a conveyor screw, which passes the carbide into the tank when a crank is turned. Taps and connections for charging either a gasometer or high-pressure receivers are provided.—J. A. B.

*Acetylene from Calcium Carbide and Water, Impts. in and connected with Apparatus for the Production of.* T. Thorp, Whitefield, and F. G. Marsh, Manchester. Eng. Pat. 19,823, Aug. 28, 1897.

A BELL gas holder, by means of a rod passing within the inlet pipe, operates the valve between a carbide chamber and a water tank. Granulated carbide passes from the chamber to the tank when the holder descends. A chamber with interlocking lid and outlet valve to the carbide chamber, is provided for recharging the latter. The interlocking device is described in detail.—J. A. B.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Petroleum Springs in Italy.* T. Tamarelli. R. Istituto Lombardo di Scienze e Lettere di Milano, May 20, 1897. Chem. Zeit. 21, [69], 603.

According to Prof. Tamarelli, petroleum has been found in a boring recently made near Salsomaggiore. It issues from clefts, which traverse the saliferous marls in planes at right angles to the dip, and is mixed with brine (which is found in all borings in the district). The petroleum, from a depth of 618 metres, is accompanied by quantities of gaseous hydrocarbons, which cause intermittent sputterings in the stream. Further discoveries of oil are to be expected from the geological nature of the ground.—J. T. D.

*Petroleum Purification of.* Badische Anilin und Soda-industrie (Ger. Pat. 95,702). Zeits. für angew. Chem. 1897, [19], 629.

It is found that the sulphonated products formed and left dissolved in the oil when treated with fuming sulphuric acid, can be removed by agitation with a small quantity of ordinary (75 to 100 per cent.)  $\text{H}_2\text{SO}_4$  previous to the alkali treatment, thus effecting a degree of purification unattainable by the ordinary method. The quantities given as most suitable in the examples cited in the specification are, in the case of—

*Galician Crude Benzine* (sp. gr. 0.730).—Ordinary  $\text{H}_2\text{SO}_4$  to remove water, 0.25 per cent.; fuming acid treatment, 0.5 per cent. of  $\text{H}_2\text{SO}_4$  (60 per cent. free  $\text{SO}_3$ ); after-washing, 0.25 per cent. of ordinary (92 per cent.)  $\text{H}_2\text{SO}_4$ .

*Cracked Galician Petroleum* (sp. gr. 0.825).—Freed from water, then mixed with 1 per cent. of 20 per cent. fuming  $\text{H}_2\text{SO}_4$ , followed by  $\frac{1}{2}$  per cent. of ordinary (94 per cent.) acid.

*American Machine Oil* (sp. gr. 0.905).—Fuming acid treatment with 3 per cent. of  $\text{H}_2\text{SO}_4$  (5 per cent. free  $\text{SO}_3$ ); after-treatment with 2 per cent. of (92–96 per cent.) ordinary acid.

*Russian Lubricating Oil* (sp. gr. 0.930).—Treated with 4 per cent. of 5 per cent. fuming  $\text{H}_2\text{SO}_4$ , followed by 1 per cent. of ordinary concentrated acid.

*Galician Paraffin Press Oil* (cracked distillate, sp. gr. 0.902).—Fuming acid treatment with 7 per cent. of 10 per cent. fuming  $\text{H}_2\text{SO}_4$ ; after-treatment with 2 per cent. of 85 per cent. acid.

The treatment is claimed as efficacious in the case of all distillates, cracked or uncracked, though more particularly adapted for heavy oils and cracked distillates.—C. S.

*Petroleum, Contribution to the Knowledge of the Chemical Behaviour of.* Action of Sulphuric Acid. R. Zdziozicki. Zeits. für angew. Chem. 1897, [18], 587–592.

A NUMBER of samples of Galician and Russian crude petroleum were treated by agitation with an equal volume of concentrated sulphuric acid at room temperature, the same treatment being also applied to samples of the same oils after division into four fractions of distillate between 150° and 300° C., and a residue boiling above 300° C. The proportion of the lighter fractions absorbed by the acid, was comparatively small, ranging between 0.20 and 1.05 per cent., whereas from 11.80 to 27.20 per cent. of the residue above 300° C. was absorbed. On the other hand, the difference between the amount of heavy constituents present in the crude oil, and in the same oil after the above acid treatment (after deduction of the proportion absorbed by the acid), indicated an increase in these heavier components of from 8.04 to 12.97 per cent. This increase is most easily explained as the result of polymerisation of the unsaturated hydrocarbons, and this confirms the assumption of Engler and Jezioranski (this Journal, 1896, 191) respecting the composition of the heavier fractions of petroleum.

In view of these results the author does not consider that such a treatment would have any beneficial practical result on the medium fractions of petroleum distillate, since any

consequent increase in the yield would be chiefly confined to benzine. On the other hand, in the case of lubricating oils, a considerable proportion of the intermediate oils is converted, by polymerisation (in the treatment of the crude oil), into heavier and more viscous products, resulting in an increased yield of cylinder- and similar oils, the quality of the distillate being also improved by the elimination of the lighter impurities which ordinarily increase the difficulty of distillation.

From experiments made with a view to the utilisation of this acid treatment in practice, the author finds the most suitable quantity of acid to be 5 per cent., larger amounts effecting but a slight extra separation of acid tar, whilst reducing the consistency of the same. The latter result also ensues in proportion as the percentage of monohydrate in the sulphuric acid used, decreases, acid of 66° B. producing a thicker and harder tar than weaker grades of acid. The difficulty of separating this tar from the oil prevents the application of this treatment to residuum.

The purified crude oil requires to be neutralised before distillation in order to avoid the decomposition of the residual acid therein. Owing to the readiness with which troublesome emulsions are formed on the addition of alkali, this operation is far from easy, and involves a protracted period of rest for the deposition of sediment. On the other hand, no final washing with water is required.

The purified crude oil is almost entirely free from pitchy, asphaltic, and resinous matters, and is much lighter in colour, the fluidity being also greater; the distillates require but little purification, and the residue left after the petroleum fractions have passed over, will form a very good consistent lubricant without any further treatment than distillation by superheated steam.

The author turned his attention to the utilisation of the acid tar for the manufacture of lac in the same manner as the acid tar from the ordinary refining process, but found that the resulting product is different, more nearly resembling true asphaltum lac. This circumstance strengthens his opinion that the product of the action of sulphuric acid on crude petroleum is, when freed from acid, identical with natural asphaltum or bitumen.

This utilisation of the 10 to 15 per cent. of crude oil, otherwise wasted, should nearly or quite cover the cost of the acid treatment. It is, however, pointed out that the method is not a universal one, since not all petroleum can be advantageously worked up for asphalt and bitumen.

—C. S.

*Petroleum: Modifications produced by Heat and Pressure.* R. Zdziozicki. Zeits. für angew. Chem. 1897, [19], 619–623.

IN these researches the behaviour of the oil towards sulphuric acid before and after distillation (or heating under pressure) was taken as an index of the alterations produced. The test consisted in shaking up equal volumes (50 c.c.) of oil and concentrated acid in a graduated tube and reading off the amount of oil absorbed at the end of 48 hours. In examining the effect of distillation, all the distillates up to 300° were, on cooling, united, returned to the retort, and filtered, this being considered preferable to testing the distillates and residue separately. The results obtained were as follows:—

Crude Oil from	Percentage Volume of Crude Oil absorbed by $\text{H}_2\text{SO}_4$ in the	
	Undistilled.	Distilled Condition.
	Per Cent.	Per Cent.
Sloboda Raugurska .....	26.8	23.70
Krosno .....	24.2	23.20
Schołnica .....	11.8	12.40
Halachani .....	25.2	21.60
Bibi Ejbet .....	27.4	22.00
Sabuntschil .....	22.6	18.60

the absorption (contrary to anticipation) being less after distillation than before, except in the case of the Schołnica oil. Nevertheless, as repeated distillations of the fraction

250°–300° C. of the Sloboda oil (as well as of the crude oil itself) showed, decomposition does occur, though its effects on the ratio of absorption by  $H_2SO_4$  are masked by other phenomena, which the author attributes to polymerisation. In favour of this view the author cites the constant increase in the amount of residue obtained when a previously distilled crude oil is fractionated. This polymerisation occurs only during the first distillation—a circumstance testifying against the prevalence of a distillation temperature of 300° C. at the time the oil was in course of formation; and from one experiment it seems probable that temperatures above 200° C. are also out of the question.

The results obtained by heating crude oil free from water, in sealed tubes for 3 to 4 hours at 200° C. and 240–250° C., are as follows:—

Crude Oil from	Percentage Volume absorbed by $H_2SO_4$ in 48 Hours.		
	Heated in Sealed Tube to		
	Ordinary Crude Oil.	200° C.	240–250° C.
	Per Cent.	Per Cent.	Per Cent.
Sloboda Rungurska ...	26.80	27.66	26.63
Krosno .....	24.20	..	63.68
Balachani .....	26.20	32.30	30.86
Sabuntsehi .....	22.60	..	65.06
Romani .....	17.85	..	38.19

show a great increase in constituents soluble in the acid, except in the case of Sloboda oil, which was rich in paraffin (9 per cent.). The acid was added to the second and fourth oils in this table as soon as cooled after the heating was completed, but the other oils were left without acid until the second day.

From the above results the author concludes that only the petroleum poor in paraffin and consisting principally of naphthenes, are so changed by heat as to be partly modified by intermolecular alteration into unsaturated hydrocarbons, the temperature employed precluding the decomposition of the paraffin series. The presumption is that ring-naphthenes, i.e., polymethylenes isomeric with olefines, are here converted into the latter bodies; but this explanation does not exclude the possibility of dynamic isomerism between naphthenes and olefines. At any rate, the conversion of the isomer of propylene—differing from propylene in its behaviour towards bromine and sulphuric acid—into true propylene by the influence of heat justifies the assumption that analogous modifications are possible among higher members of the naphthene or cyclo-olefine series.—C. S.

#### PATENTS.

*Benzene, Toluene, and other Products from Mineral Oils and Liquid Tars; Impts. in Obtaining.* J. Meikle, Maryhill, Glasgow. Eng. Pat. 23,619, Oct. 21, 1896.

This invention consists in operating on the oil in a retort containing coke or other suitable carbonaceous material and maintained at about red heat, the oil being injected by the aid of superheated steam. The gaseous mixture is led through pipes to suitable condensers, the benzene and toluene being thereby separated from the gas, which is then used for heating or illuminating purposes. The material employed may, for example, be an oil such as is obtainable from coal or coal-tar, and after all the benzene has been separated from it by the ordinary process. Oils very suitable for the purpose are light creosote oils or light tar oils.—D. B.

*Benzol and similar Hydrocarbons, Improved Process for obtaining.* [Decomposition of Tar Oils by Heat.] G. Schultz, Munich, Germany. Eng. Pat. 26,771, Nov. 25, 1896.

This invention relates to the production of benzene and similar hydrocarbons in considerably larger quantities than has been hitherto possible in the ordinary process of gas manufacture. According to the methods formerly employed, only comparatively small quantities of benzene,

toluene, xylene, naphthalene, and anthracene are obtained, about 50 per cent. of the tar constituting pitch, and 40 per cent. oily residues. The latter are the oils remaining from the treatment of coal tar, after the removal of the hydrocarbons contained therein. By the present invention, these oils are conveyed into highly heated or glowing retorts or hot coke ovens, which are preferably provided with a suction appliance. The vapours, which, in consequence of the decomposition resulting thereby, contain aromatic hydrocarbons, such as benzene, toluene, and the like, are condensed in the usual manner.—D. B.

*Orthotoluenesulphonic Chloride, Method of Producing and Purifying.* W. Majert, Berlin, Germany. Eng. Pat. 6581, March 12, 1897.

Hiemrich orthotoluenesulphonic chloride has been separated from the para compound by crystallising the former out of a mixture made in the cold. The liquid portion thus obtained, contains, as a rule, 70 per cent. of ortho- and 30 per cent. of para chloride. These two chlorides cannot be separated by fractional distillation in a vacuum. It has, however, been found that almost pure orthotoluenesulphonic chloride can be obtained in the following manner:—About 30 to 40 parts by weight of the above mixture are distilled off in a vacuum. The distillate consists of almost chemically pure ortho compound. The residue is cooled, and from the same there are obtained by crystallisation from 10 to 12 parts of para compound. This is separated from the liquid and a further portion of ortho compound is distilled off, and so on. The residue is cooled to the ordinary temperature.—D. B.

#### IV.—COLOURING MATTERS AND DYES.

*Indoïns, Note on the.* L. D'Andiran. Bull. Soc. Ind. Mulhouse, 1897, 245–248.

THE Indoïns are basic colouring matters prepared by combining diazo-safranines with  $\beta$ -naphthol. Their production was patented by Beyer and Kegel in 1885, but the patent was allowed to lapse, and in 1891 the Badische Anilin und Soda Fabrik again patented the process, including the treatment of the resulting compounds with acid in order to render them soluble. According to a later patent of the same firm, soluble dyestuffs are also obtained by repeated washing with water of the insoluble azo compounds. Various other patents, of which the author gives a *résumé*, and which differ from the above only in minor details, have been subsequently taken out.

In the first patent of the Badische Anilin und Soda Fabrik the transformation of insoluble bases into their soluble salts is spoken of, while in their second patent the insolubility is attributed to the presence of mineral matter, which is removed by repeated washing. According to a patent of Dahl and Co., insolubility is due to a combination of safranine-azo-naphthol with sodium. Analysis, however, reveals only slight traces of sodium; and, in the author's opinion, insolubility is caused here, as in many other cases, by the presence of a slight excess of alkali.

An excess of mineral acid also precipitates the colouring matter from its solution, the precipitate consisting of a mixture of mono- and diacid salts.

The Indoïns are sold in the form of black pastes or bronze-like powders, and frequently contain a slight admixture of Methylene Blue to increase the brilliancy of the colour. The shades which they yield on tannin-mordanted cotton are very similar to indigo blues, and are much faster to soap and to light than other basic colours. They can also be dyed on cotton without a mordant, but with less satisfactory results.—R. B. B.

*Bismarck Brown.* E. Taüber and F. Wabler. Ber. 30, 2111–2117.

ALTHOUGH one of the earliest of the artificial organic dyestuffs, the constitution of Bismarck Brown (Vesuvine, Phenylene Brown) cannot be considered as established, and probably none of the Bismarck Browns prepared on a manufacturing scale, or in the laboratory, are chemically identical products. According to Caro and Griess (in 1867),

Bismarck Brown consists of the hydrochlorides of three bases, of which triamidoazobenzene preponderates. More recently, doubt has been thrown upon this view, owing to the fact that the amount of nitrite required in the preparation of the brown on a large scale points to the molecule consisting of the residues of three *m*-phenylene diamines, connected by two azo groups. This leads to the assumption that phenylene-disazo-*m*-phenylene diamine is the chief constituent. There are, however, three formulæ possible for a substance having this composition. In order to convert the whole of the *m*-phenylene diamine into dye-stuff, a weighed quantity of *m*-phenylene diamine hydrochloride was treated with sodium nitrite. The formation of the dye-stuff is accompanied by a copious evolution of nitrogen, which is not due to an excess of nitrite, since a considerable amount of *m*-phenylene diamine is also present. The amount of nitrogen evolved corresponds to 29.1 per cent. of that contained in the *m*-phenylene diamine, since half the evolved nitrogen comes from the nitrite. The proportion of nitrite to *m*-phenylene diamine is 5:6. By taking the mono- instead of the dihydrochloride, no evolution of gas takes place, but when the reaction is finished, unchanged nitrite is found side by side with *m*-phenylene diamine, so that triamidoazobenzene is not the only product. In order to obtain a yield of dye-stuff without any evolution of gas, the authors find that three molecular proportions of *m*-phenylene diamine, together with four molecular proportions of hydrochloric acid, require two molecular proportions of nitrite, but the product obtained is not homogeneous. In order to obtain triamidoazobenzene of undoubted constitution, acetyl-*m*-phenylene diamine was diazotised and combined with *m*-phenylene diamine, the acetylated dye-stuff being finally hydrolysed. Thus prepared, triamidoazobenzene crystallises from hot water or benzene, in needles melting at 114° C. This product was not found in commercial Bismarck Browns, but only in that product obtained from three molecular proportions of *m*-phenylene diamine, four molecular proportions of hydrochloric acid, and two molecular proportions of nitrite. No triamidoazobenzene could be detected in the brown from *m*-phenylene diamine dihydrochloride or in a good commercial sample. The brown for this purpose, after basifying, was extracted in a Soxhlet's apparatus with benzene, 15 grms. of base giving 10 grms. of crystalline extract. The pure substance melts at 118° C., is almost insoluble in water (difference from triamidoazobenzene), and gives numbers on analysis corresponding to a disazo dye-stuff containing three *m*-phenylene diamine radicals.—F. A. L.

*Bismarck Brown.* R. Möhlau and L. Meyer. Ber. 30, 2203—2206.

THE authors have commenced a research on the products obtained by the action of sodium nitrite on *m*-phenylene diamine known commercially as Bismarck Brown, Vesuvine, Phenylene Brown, and Manchester Brown (see also Täuber and Walder, Ber. 30, 2111; see previous abstract). In order to test the statement of Caro and Griess that triamidoazobenzene is the chief product in the mixture obtained, the authors, in an analogous manner to Täuber and Walder, have prepared this substance in a pure state by the action of diazotised phenylene oxamic acid on *m*-phenylene diamine. The product so obtained, after crystallisation, forms groups of concentric prisms melting at 189° C. On hydrolysis with dilute sulphuric acid (100:7.5) they obtained a product which possessed all the properties already ascribed to triamidoazobenzene. When boiled with fused sodium acetate and acetic anhydride it yields the triacetyl compound melting at 264° C. Attempts to produce triamidoazobenzene exclusively, by the action of sodium nitrite on *m*-phenylene diamine were unsuccessful, the best results being obtained by reacting with two molecular proportions of *m*-phenylene diamine hydrochloride on one molecular proportion of sodium nitrite in presence of three molecular proportions of sodium acetate. The investigation of five commercial Bismarck Browns stated to be obtained from *m*-phenylene diamine, led to the result that all contained a product having the composition of a triamidoazobenzene, although the amount present was small in proportion to the bulk of the product.—F. A. L.

*Nitronaphthalene, The Commercial Preparation of.* W. H. Krug and J. E. Blumen. J. Amer. Chem. Soc. 1897, 19, 532.

*Indigo, Assay of.* A. Brylinski. Bull. Soc. Ind. Mulhouse, 1897, 331.

See under XXIII., page 938.

## PATENTS.

*Dyes, Impts. in the Production of.* L. P. Marchlewski, Manchester, E. S. Wilson, Strood, and E. Stewart, London. Eng. Pat. 21,498, Sept. 28, 1896.

ACCORDING to Eng. Pat. 24,418 of 1895, a substance has been separated from crude cotton-seed oil which can be obtained from glacial acetic acid and alcohol in yellow crystals, and is easily soluble in alcohol, ether, boiling acetic acid, and alkalis, but insoluble in water. This product has been termed *Gossypol*, and can be used, according to the specification, in two ways, for the production of dye-stuffs, according to the following methods. *Oxygossypol Brown* is obtained by dissolving 20 kilos. of *Gossypol* in a solution of 15 kilos. of caustic soda in 300 litres of water, and blowing a current of air through the solution for several hours, until no further increase in the tinctorial value takes place. The dye-stuff produced gives brown shades on mordanted wool or cotton, and when a sample so dyed attains a maximum in strength, the current of air is stopped and the solution is acidified, when the dye-stuff is precipitated. Another dye-stuff may be obtained from *Gossypol* by heating 10 kilos. of it with 50—100 kilos. of crystallised sodium sulphide, with or without the addition of sulphur. The temperature is maintained for some time at 120° C. and is then raised to 250° C. for several hours. The dye-stuff produced gives brown shades on unmordanted cotton, and may be employed in the crude state, or purified by dissolving in sodium sulphide and precipitating with an acid. The shades may be intensified by passing the dyed goods through solutions of metallic salts, such as copper sulphate, potassium bichromate, &c. The products obtained according to the specification may also be used for printing. —T. A. L.

*Blue Dye-stuff suitable for Dyeing Wool, Production of a.* S. Pitt, Sutton. From L. Casella and Co., Frankfurt-on-Main, Germany. Eng. Pat. 24,134, Oct. 29, 1896.

ALTHOUGH the diazo derivatives of the periamidonaphthol sulphonic acids are very sensitive to alkalis, they will combine in weak acid solutions to form azo dye-stuffs. For instance, according to Eng. Pat. 12,556 of 1896 (this Journal, 1897, 531), a technically useful dye-stuff has been obtained by combining diazotised 1.1'.3.3'-amidonaphthol disulphonic acid with alkylnaphthylamine. The patentees now find that when the same diazo compound is combined with 1.5-amidonaphthol, a blue dye-stuff is obtained, very fast to light, and giving level shades:—32 kilos. of 1.1'.3.3'-amidonaphthol disulphonic acid are diazotised with 35 kilos. of hydrochloric acid and 7 kilos. of sodium nitrite, and the diazo compound is filtered off, washed with brine, and suspended in 500 litres of water. To this is then added a solution containing 16 kilos. of 1.4'-amidonaphthol, dissolved in 15 kilos. of hydrochloric acid and 300 litres of water. Finally, a solution of 30 kilos. of sodium acetate is run in, when, after a short time, a clear blue solution is obtained. After neutralisation with 20 kilos. of sodium carbonate, the dye-stuff is salted out. In place of the 3.3', other disulphonic acids, such as the 4.3', 3.2', or 2'.3' may be used, or the 4-sulphonic acid and analogous dye-stuffs are also obtained if the 1.4'-amidonaphthol be replaced by the 1.4'.2' or the 1.4'.3'-amidonaphthol sulphonic acid.—T. A. L.

*Sulphinic Acids of the Aromatic Series, The Manufacture or Production of.* H. E. Newton. From "The Fabrikanten vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 26,139, Nov. 19, 1896.

By acting on the diazo compound of an aromatic amine with copper powder in presence of sulphurous acid, nitrogen is evolved, and the corresponding sulphinic acid is produced. For example, 1 kilo. of aniline is dissolved in 15 litres of water and 3 kilos. of concentrated sulphuric acid, and diazotised in the usual manner. The diazo solution is then added with rapid agitation to an excess of an aqueous solution of sulphurous anhydride to which 6 kilos. of copper powder have been added. A rapid evolution of nitrogen takes place, and when the diazo compound has disappeared the reaction is finished. The sulphinic acid produced can be extracted with ether, and has the properties of benzene sulphinic acid, melting at 84° C. 1 kilo. of 1-naphthylamine sulphinic acid is mixed with 3 kilos. of concentrated sulphuric acid and 15 litres of water, and diazotised in the usual manner by means of sodium nitrite. A current of sulphurous acid is then passed in whilst carefully cooled, and subsequently 6 kilos. of copper powder are added. When the evolution of nitrogen has ceased, the formation of the sulphinic acid is complete. After making alkaline with sodium carbonate, the sodium salt is separated by means of salt. The new acid is easily soluble in water, and crystallises therefrom in leaf-like plates. The barium salt is a flaky, white precipitate, sparingly soluble in water, and is obtained by adding barium chloride to a solution of the sodium salt. On treating the new acid with potassium permanganate, it is converted into 1,4-naphthalene disulphonic acid.—T. A. L.

*Azo Colouring Matters [Violet, Blue, Brown], Production of New.* W. H. Claus, A. Rée, and L. Marchlewski, Manchester. Eng. Pat. 26,210, Nov. 20, 1896.

According to Eng. Pat. 18,020 of 1896 (this Journal, 1897, 676), dyestuffs are obtained from the azo compound produced by combining diazotised  $\gamma$ -amidonaphthol sulphonic acid with itself in an alkaline solution. The present specification describes dyestuffs which are formed from the azo compound produced in an acid solution. These products have the following general formula:—

where D is the radicle of a tetrakisalide *p*-diamine, X is an amine, phenol, amidophenol, naphthol, amidonaphthol, or a sulphonic or carboxylic acid thereof; N represents nitrogen atoms, and G.2 an amido-azo compound, produced by combining diazotised  $\gamma$ -amidonaphthol sulphonic acid with itself in an acid solution. The combinations take place according to different methods, of which the two following are the most general:—(1.) 2 mols. of a tetrakisalide *p*-diamine are combined in an alkaline solution with 1 mol. of the amido-azo compound G.2, and the intermediate compound is allowed to act on 2 mols. of an end component. (2.) 1 mol. of a *p*-diamine is combined in an acid or alkaline solution with 1 mol. of an end component. 2 mols. of the intermediate compound obtained are then allowed to react with 1 mol. of the amido-azo compound G.2. The following example illustrates one of the methods by which dyestuffs may be obtained. The tetrazo solution from 36.8 kilos. of benzidine is poured into a cold solution of sodium carbonate so that the whole remains slightly alkaline, and to this is added 52.2 kilos. of  $\gamma$ -amidonaphthol sodium sulphate. When the formation of the intermediate compound is complete, 200 litres of water containing 39 kilos. of sodium carbonate and 56.9 kilos. of the *o*-amido compound (from diazotised  $\gamma$ -amidonaphthol sulphonic acid and amidonaphthol disulphonic acid II in an acid solution) are added, and the whole is stirred for some time and finally heated to 50°–80° C. The dyestuff produced gives reddish black-blue shades on unmoirated cotton. It may be diazotised either on or off the fibre, and on combination with *m*-tolylene diamine, resorcinol, or  $\beta$ -naphthol gives dark-blue and violet black-brown shades.—T. A. L.

*Colouring Matters, Greys, Blacks, Suitable for Dyeing Unmoirated Cotton, Impts. in the Manufacture of.* A. Ashworth, Bury. Eng. Pat. 18,762, Aug. 13, 1897.

The dyestuffs referred to are obtained by the action of sulphur and sodium sulphide on (1) aromatic nitro, amido, or nitro-amido hydroxycarboxylic acids; (2) a mixture of any of these acids with substances such as phenols or naphthols, nitro- or nitrosophenols or naphthols, amido-phenols or naphthols, sulphonic acids of the foregoing, sulphated or nitrosulphated compounds of the benzene or naphthalene series, diamido benzenes and naphthalenes or their sulphonic acids, cane sugar and glucose; (3) azo dyestuffs of the Alizarin Yellow type (action of diazotised nitraniline on salicylic acid), or such containing as one component an amido or nitro-amido hydroxycarboxylic acid. The following is an example of the method employed:—A mixture of 20 kilos. of nitrosalicylic acid and a concentrated solution of 60 kilos. of sodium sulphide is heated for 2 hours at 125° C., when 16 kilos. of sulphur are added and the temperature is increased to about 200° C., at which it is maintained until the melt becomes solid. The product is easily soluble in water, and the solution dyes cotton grey to black shades, which may be intensified by treatment with oxidising agents.—T. A. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Oxy-cellulose.* L. Vignon. *Comptes Rend.* 1897, 125, [12], 418.

See under VI., page 908.

### PATENTS.

*Jute Fibre, Method for Improving the Colour of Raw.* C. O'Brien and J. Shearer, Dundee. Eng. Pat. 20,737, Sept. 19, 1896.

The jute is immersed for one minute in dilute acid—phosphoric, sulphuric, hydrochloric, or oxalic—and then dried in a hydro-extractor or by other means.—R. B. B.

*Waterproofing Silk, Cotton, Wool, and other Threads, and Fabrics made therefrom, Impts. in and relating to.* W. C. Kipling and E. Arnold, Sudbury, Suffolk. Eng. Pat. 22,197, Oct. 6, 1896.

The waterproofing solution is prepared by dissolving 3 oz. of aluminium sulphate, 1 oz. of lead acetate, and  $\frac{1}{2}$  oz. of tannin in 1 gallon of distilled water, and consists therefore essentially of acetate of alumina. The advantages claimed for its use are decreased cost, and freedom from odour; and it is stated that the waterproofing is in no way noticeable.—R. B. B.

*Nitrocellulose, A New or Improved Solvent or Solvents for, whereby Improved Solutions are obtained.* R. W. Strehlenert, Stockholm. Eng. Pat. 22,540, Oct. 10, 1896.

Artificial silk, when prepared in the ordinary way from cellulose, has a marked tendency to absorb water, and when in a wet condition, its strength is reduced by about 90 per cent. The patentee claims the process for the production of artificial silk which shall be proof against the action of water, consisting in either adding to or mixing with the solvent (ethyl alcohol, methyl alcohol, ether, &c.) for the nitrocellulose, before drawing out the threads, formic aldehyde, acetic aldehyde, paraldehyde, benzaldehyde, or other substances of the same group, to the extent of as much as 15 per cent. of the weight of nitrocellulose, or in treating the silk, after being spun, with one of the above-mentioned substances.—A. S.

*Felt, Impts. relating to, and Process for its Production.* G. Kreuter, The Hague, Holland. Eng. Pat. 17,541, July 26, 1897.

This invention consists in the manufacture of a felt composed of silk and wool fibres. Silk rags are washed, carbonised, disintegrated, and carded by the methods employed for woollen rags, and subsequently treated with alum and manganese ore. A treatment with oil and soap next follows for the purpose of cleansing and opening the

fibres. The material thus obtained, is mixed with natural or recovered wool in the mixing machine, about 30–40 per cent. of silk fibre being employed. The mixed material is then made into felt in the usual manner.

The advantages claimed for this felt are, that it is softer and more delicate than woollen felt, possesses a finer felt or "grip," and receives a very high gloss, whilst the hat, &c., does not need such high pressure in finishing as it otherwise would, and can be produced out of less material. Further, it is stated that the shape and appearance are unaffected by rain.—R. B. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Oxycellulose.* L. Vignon. *Comptes Rend.* 1897, 125, [12], 448–450.

The author describes the preparation and some of the properties of oxycellulose. Pure cellulose was treated for half an hour successively in the following four baths (aqueous solutions):—(a) 1 per cent.  $\text{Na}_2\text{CO}_3$  at  $100^\circ$  (30 minutes at  $100^\circ \text{C.}$ ); (b) 1 per cent.  $\text{NaOH}$ , for 30 minutes at  $100^\circ$ ; (c) 0.1 per cent. solution of  $\text{HCl}$  (of  $22^\circ \text{B.}$ ) for 30 minutes in the cold; and (d) 1 per cent.  $\text{Na}_2\text{CO}_3$  for 30 minutes in the cold. After this treatment the cotton was washed with boiling distilled water, alcohol, and then dried. It lost about 10 per cent. of its weight during the process. The effect of several oxidising agents was tried, but a mixture of hydrochloric acid and potassium chlorate gave the best results.

*Preparation.*—30 grms. of the purified cotton were introduced into a boiling solution of 150 grms. of potassium chlorate in 3,000 c.c. of water, and then 125 c.c. of hydrochloric acid (of  $22^\circ \text{B.}$ ) were gradually added. The liquid was kept near the boiling point for an hour, decanted, washed by decantation with distilled water until free from acid, then with alcohol, and dried in the air, and finally on filter-paper and porous tile. The white powder thus obtained possesses the following properties:—

*Properties.*—Under the microscope, oxycellulose has the appearance of very short filaments. It turns yellow at  $100^\circ \text{C.}$ , is insoluble in neutral reagents, and is coloured blue by iodine and sulphurous acid; the coloration being more rapid and distinct than in the case of cellulose itself.

From the results obtained on fusion with potash at  $180^\circ \text{C.}$  it appears that oxycellulose is a mixture of 75 per cent. of oxycellulose, and 25 per cent. of cellulose. The heat of combustion varies between 4,133 and 4,124, that of cellulose being 4,221–4,190. The heat disengaged on immersing 10 grms. of substance in normal potash at  $13^\circ \text{C.}$  was:—

	Per 100 Grms.
Cellulose .....	0.74 cal.
Oxycellulose .....	1.39 "

The following quantities of dye-stuff, as measured by the colorimeter, were taken up by 1 gm. of the substance on dyeing for one hour at the boiling point:—

	Safranine.	Methylene Blue.
	Grm.	Grm.
Cellulose .....	0.000	0.002
Oxycellulose .....	0.007	0.005

Oxycellulose and also the yellow liquid obtained on extraction with potash act as powerful reducing agents on Fehling's solution. The substance remaining behind, after extracting with hot potash, possesses no reducing properties. Since oxycellulose gives Schiff's reaction with magenta and sulphurous acid, it appears to be of an aldehydic nature.—J. S.

### Heating Apparatus for Dye Vessels. W. Stermer.

Färber Zeit. 1897, 8, [11], 165–166.

Of three forms of heating apparatus shown in the figures, used for the purpose of heating dye-baths with directly-introduced steam, it is known that form I. is unsatisfactory, owing to the baths becoming more rapidly heated at the end where the steam enters the horizontal pipe—a circumstance

which leads to irregular dyeing. Form II. has recently been recommended (Oesterr. Wollen- und Leinen-Ind., 16, No. 17). The author, however, prefers arrangement

III., which he has used for some time with satisfactory results. In this the main steam-pipe is divided into two branches as shown, and care is taken that the perforations in the horizontal pipes are of exactly the same size, and that, in working, they are kept free from threads, lint, dyewoods, &c.

The author, further, points out the necessity in introducing the dyestuff and mordant solutions, of distributing them regularly at the back of the steam-pipe so that they may be diffused evenly into the bath.—E. B.

*Plumbite of Soda* [ $\text{Na}_2\text{PbO}_2$ ], with and without Glucose. *The Comparative Mordanting Power of.* A. Scheurer-Bull. Soc. Ind. Mulhouse, 1897, 258–260.

In 1894, Bonnet stated that the power of caustic soda to dissolve lead oxide is increased by the addition of glucose, and the mordanting power of the plumbite of soda thereby improved. The present author finds, however, that although the first of these statements is correct, yet, when a solution containing glucose is compared with one not containing this addition, by mordanting samples of cotton with each and passing into potassium bichromate solution, the colour is of equal depth in both cases. The percentage of lead in the solution containing glucose was 9.1; in the other, 5.4; and the author therefore concludes that the additional amount of lead brought into solution in the presence of glucose cannot be fixed on the fibre. He adds, however, a statement of Bonnet, that the advantage of the plumbite of soda containing glucose, consists in its less alkalinity compared with the ordinary plumbite.—R. B. B.

*Organic Solvents in Printing* [with Induline Dyestuffs]. C. Gassmann. Bull. Soc. Mulhouse, 1897, 237–244.

The author has compared the use of a large number of derivatives of glycerin as solvents for the Indulines. Many of his results will be found described in a previous paper (Monit. Scient. 1896, 10, 348; this Journal, 1896, 584). No good results are obtained with derivatives containing the aldehyde group COH. The most useful solvents are the glycerides of levulinic acid and of tartaric acid, and their acetyl derivatives, these compounds having a greater solvent power for Indulines than is possessed by acetin. The glyceryl derivative of tannic acid is not suitable, owing to precipitation of tannate of Induline. The above solvents are not found useful in the case of Rosindulines.

—R. B. B.

*Dyeing with Cotton Substantive Dyestuffs at Low Temperatures.* E. Grossmann. *Färber Zeit.* 1897. 8, 11, 166—167.

It is usually recommended that dyeing with cotton substantive dyestuffs should be performed at or near 100° C.

This is found in the majority of instances to be the most effective method of applying the dyestuffs in question, but there are a number which dye better at 40—50° C. These are, for example: Erikas B N and 2 G N; Brilliant Congos G and R; Congo Rubin; Orange T A; Curcumin S; Chrysophenin G; Mikado Yellows 3 G and 6 G; Chicago Blues 6 B, 4 B, 2 R, and 4 R; Columbia Blues G and R; and Zambesi Black D. Of these, at the lower temperature, Chicago Blues 6 B and 4 B and Columbia Blue G give slightly redder shades, Brilliant Congo R and Orange T A give yellower shades, and Brilliant Congo G is brighter than when dyed at 100°. Other dyestuffs dye at 40°—50°, and at 100° C., colours similar in intensity but different in shade. Examples are Brilliant Orange G and Heliotrope B, the former of which, at 40—50°, dyes much redder, the latter considerably bluer, than at 100°. Also, at the lower temperature, Columbia Red 8 B yields bluer, Chrysamine G greener, Zambesi Brown G and Deltapurpurin G give clearer, and Congo Sky Blue and Mikado Browns B and G give redder and purer shades than are usually obtained.

It is a striking fact that the dyestuffs which dye cotton better at the lower temperatures, are all compounds which dye with difficulty. It is found, indeed, as a rule, that the less readily a cotton-substantive dyestuff is absorbed by cotton, the better, relatively, does it dye at 40°—50°.

Chrysophenin G and Erikas B N and 2 G N may be satisfactorily applied at the ordinary temperature, and, in general, for pale shades, dyeing in the cold is to be recommended in the case of dyestuffs dyeing with difficulty.

It is also advantageous in the dyeing of mixed woollen and cotton fabrics with dyestuffs which at 100° yield darker colours on wool than they do on cotton, to dye at 40°—50°, in order to obtain even shades. Chrysophenin G,

Erikas B N and 2 G N, Brilliant Congos G and R, and Zambesi Black D are instances of this class.

The colours on cotton obtained at 40—50° C. are hardly so fast to washing as those dyed at 100°; but it is to be remarked that the cotton-substantive dyestuffs generally are not very fast to washing, and the difference is almost inappreciable.—E. B.

*Mordanting of Wool with Chromium.* M. Last.

*Färber Zeit.* 8, 181—184 and 201—203.

The principal chromium mordants used for wool are potassium bichromate with either sulphuric acid, tartar, lactic acid, or oxalic acid, and chromium fluoride with oxalic acid. With certain dyestuffs, e.g., logwood, where the useful mordant is chromic acid, sulphuric acid is the best assistant, the organic assistants being useful only on account of, and in proportion to, their acidity. Tartar and lactic acid, being stronger reducing agents than oxalic acid, are to be preferred when a basic chromium mordant or a mixture of basic and acid mordant is required. This mixed mordant gives a good result with most dyestuffs, and is, on the whole, the best mordant.

When wool is mordanted with the object of fixing chromium in the basic form, the appearance of the spent liquor and the mordanted fibre is as follows:—

Mordant.	Spent Liquor.	Fibre.
K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> and tartar .....	Deep greenish-yellow	Greenish tint
K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> and oxalic acid ..	Deep yellow	Yellow
K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> and lactic acid ..	Pale yellow	Dirty green
CrF <sub>3</sub> and oxalic acid ....	Green	Pale green

It appears from this that more chromium in the basic form is taken up by the wool when mordanting with bichromate and tartar, or chromium fluoride and oxalic acid, than with bichromate and oxalic or lactic acids.

A comparison was made of various dyestuffs dyed on the above four mordants, with results shown in the following table:—

Depth and Shade of Colour obtained.

Dyestuff.	Percentage.	3 per Cent.			
		K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> , 2½ per Cent. Tartar.	K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> , 2½ per Cent. Oxalic Acid.	K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> , 3 per Cent. Lactic Acid.	Cr <sub>2</sub> F <sub>6</sub> , 1 per Cent. Oxalic Acid.
Alizarin Red S (B.A.S.F.) .....	3	Deep bluish tone	Similar to tartar	Paler	Similar to tartar
Anthracene Acid Brown R (C.)	3	Deepest	Next in depth to tartar.	"	Bright, but paler
Alizarin Orange N paste (M. L. & B.).	15	"	Paler	"	"
Alizarin Yellow G G paste (M. L. & B.).	15	Next in depth to lactic acid.	"	Deepest, but dull	Paler
Coerulein S (B.A.S.F.) .....	3	Deepest	Duller	A little paler, and brighter than with tartar.	Very yellowish
Chrome Fast Yellow G G (Berlin).	3	As with lactic acid	Paler	As with tartar	Bright, but paler
Anthracene Brown S W (B.A.S.F.).	3	As with oxalic acid	As with tartar	Palest; very red	Deepest
Alizarin Blue S W paste (B.A.S.F.).	15	Very similar to lactic acid.	Palest; bluer	Deepest and reddest	A little bluer than lactic acid.
Alizarin Blue R R paste (M. L. & B.).	15	As with lactic acid	Paler	Redder than with tartar.	Paler
Alizarin Blue R paste (M. L. & B.).	15	"	A little deeper	"	Very similar to tartar and lactic acid.
Alizarin Blue D N paste (M. L. & B.).	15	"	Similar to lactic acid	"	Similar to tartar
Alizarin Blue A paste (M. L. & B.).	15	Similar to lactic acid	Palest	Deepest; reddish	"
Alizarin Dark Blue S paste (M. L. & B.).	15	"	Paler and redder	Similar to tartar; a little redder.	Deeper than oxalic acid
Alizarin Cyanin G G (Bayer).	3	Deepest and reddest	Paler; greenest	Between tartar and oxalic acid; reddish.	Paler; greenish
Alizarin Cyanin R R (Bayer).	3	Similar to lactic acid	As with lactic acid	Deepest	Similar to lactic acid; greenish.
Brilliant Alizarin Cyanin G paste (Bayer).	15	Similar to oxalic acid	Deepest	Paler; very greenish	Paler; very greenish
Alizarin Black W R paste (B.A.S.F.).	15	Deepest	Paler	Very similar to tartar; a little bluer.	Paler

Alizarin Blue is deepest on bichromate and tartar or lactic acid mordant. As a rule, tartar gives the bluest shades; with lactic acid, and generally with oxalic acid, redder tones

are obtained. Chromium fluoride and oxalic acid is a combination influencing the shade towards green.

The differences of shade also depend on the proportion of

organic assistant to mordant. It cannot be definitely said which is the best chromium mordant, since for each dyestuff there exists a particular mordant which yields the best result. In practice, however, it is impossible to vary the mordant in this manner, and bichromate and tartar may be considered the most generally useful.

Whittaker and Denison (J. Soc. Dyers and Colourists, 1895, 98) have estimated the amount of chromium taken up by the wool when the different assistants are employed, and they conclude that the greatest amount is fixed by using the bichromate and oxalic acid mordant. Since, however, this mordant does not give the deepest shades, it is evident that the depth of colour does not depend on the total amount of chromium fixed on the wool, but on the amount fixed in acid or basic form according to the dyestuff em-

ployed. It should also be noted that when the three assistants are used in acid-equivalent amounts, less chromium is fixed with oxalic acid than with lactic acid or tartar.

In selecting the best mordant, it is also necessary to consider the fastness of the resulting colours, especially as regards washing and light. A series of tests has therefore been carried out in this direction. With regard to fastness to light, very slight differences are shown, but, in respect of fastness to washing, the shades dyed on bichromate and oxalic acid mordant are inferior to the rest. In order to ensure the best amount of each assistant being used, patterns were mordanted with 3 per cent. of mordant and 1, 2, 3, and 4 per cent. of assistant. The best proportion of assistant and the fastness to washing are illustrated in the following table:—

Best Amount of Assistant and Fastness to Washing of the Shades obtained.

Dyestuff.	Per-centage.	3 per Cent. $K_2Cr_2O_7$ , 1—4 per Cent. Tartar.	3 per Cent. $K_2Cr_2O_7$ , 1—4 per Cent. Oxalic Acid.	3 per Cent. $K_2Cr_2O_7$ , 1—4 per Cent. Com- mercial Lactic Acid.	3 per Cent. Chromium Fluoride, 1—4 per Cent. Oxalic Acid.
Alizarin Red S.....	3	2—3 per cent.; differ- ences slight.	1 per cent. best, espe- cially in fastness.	1 per cent. 4 per cent. is much paler.	1 per cent. best, espe- cially in fastness.
Anthracene Acid Brown.....	3	1 per cent.	1 per cent. deepest	1 per cent. deepest, but dull.	1 per cent.
Alizarin Orange N paste.....	15	2 per cent.	1 per cent.	1 per cent.	1 per cent. best in shade and fastness.
Alizarin Yellow G G.....	15	2—3 per cent. deepest, 1 per cent. brightest; fastness good.	1 per cent. deepest and fastest.	1 per cent. deepest	1 per cent. deepest and fastest.
Cerulein S.....	3	1 per cent. best; differ- ences slight.	"	"	4 per cent. deepest, but 1 per cent. fastest.
Chrome Fast Yellow G G.....	3	Differences slight; 2 per cent. deepest.	1 per cent. deepest; difference slight.	Differences slight; 2—3 per cent. deepest.	1 per cent.
Anthracene Brown S W.....	3	2 per cent. best in shade and fastness.	1 per cent.	3 per cent.	1 per cent. best in shade and fastness.
Alizarin Blue S W.....	15	2 per cent.	"	"	1 per cent.
Alizarin Blue R R.....	15	"	"	"	1 per cent.
Alizarin Blue R.....	15	"	"	2 per cent.	1 per cent. 3 per cent. is redder, deeper, and much less fast.
Alizarin Blue D X.....	15	2 per cent.; differences slight.	"	3 per cent.	2 per cent. deepest and reddish; 1 per cent. faster.
Alizarin Blue A.....	15	2 per cent.	"	3 per cent.; differences slight.	1 per cent.
Alizarin Dark Blue S.....	15	"	"	"	"
Alizarin Cyanine G G.....	3	2—3 per cent.	1 per cent. best and fastest.	3 per cent.; fastness very good.	1 per cent. greenish; 4 per cent. redder and less fast.
Alizarin Cyanine R R.....	3	1 per cent.	1 per cent.	3 per cent.	2 per cent. deepest; 1 per cent. fastest.
Brilliant Alizarin Cyanine G.....	15	2 per cent.	"	2 per cent.	1 per cent. greenish and fast; 4 per cent. reddish and not fast.
Alizarin Black W R.....	15	1 per cent. deepest; fastness good.	1 per cent. best and fastest.	2 per cent. deepest; fastness good.	1 per cent. deepest and fastest; 4 per cent. very reddish.

It appears from the above table that when tartar or lactic acid is used, the best proportions are 3 per cent. of potassium bichromate with 2—3 per cent. of assistant; in exceptional cases less assistant should be used. With oxalic acid the best proportion is 3 per cent. of bichromate or chromium fluoride and 1 per cent. of oxalic acid. These amounts give the deepest shades, and as a rule dyes which are the fastest to washing. It is noteworthy that with oxalic acid the fastness is improved as the oxalic acid is decreased, and when a small percentage is employed, the fastness compares much more favourably with that of the shades obtained with tartar or lactic acid.

An excess of reducing agent is harmful, since the increased acidity of the bath retards fixation of chromium; but a certain acidity is necessary, as shown by Whittaker and Denison, *loc. cit.*, who obtained much worse results with neutral potassium oxalate than with the acid salt or the free acid. The author cannot confirm the statement of Körner that by employing the correct proportion of reducing agent, the chromium is converted into the violet modification, for he finds that the mordant bath remains yellow even after two hours' boiling.

In the case of chromium fluoride mordant, an entire change of shade frequently takes place when excess of oxalic acid is used. Since oxalic acid cannot act as a reducing agent towards chromium fluoride, its effect must

be wholly due to its acid properties, whereby hydrofluoric acid is liberated and the chromium brought into solution.

A chromium mordant has lately been introduced which contains organic assistants (especially lactic acid) and also sulphuric acid. It possesses the advantage of completely exhausting the mordant bath, but the disadvantage of "going on" very quickly and therefore less evenly.—R. B. B.

*Indigo, Printing of, on Cotton Fabrics.* C. Kurz. *Revue Gen. des Mat. Colorantes*, 1897, 79.

The author recommends the following as a simple method of printing with indigo:—

40 grms. of refined Java indigo are dissolved in 200 c.c. of aniline by 15 minutes' boiling. The clear solution is poured off, the residue being preserved for a second operation. On cooling, the solution deposits indigo in a finely divided condition, which enables it to be readily mixed with the thickening employed, the latter consisting of caustic soda and roasted starch. The colour is printed on goods padded with a solution of glucose at 5° B., and after printing, the pieces are dried, steamed for 2 minutes, and washed. A deep blue is produced with 40 grms. of indigo per litre of printing-colour, and the advantage of the method depends upon the extremely fine state of subdivision of the reprecipitated indigo.—R. B. B.

*Colouring Matters Dyed on Nineteen Metallic Mordants.* A. Scheurer and A. Bøylinski. Bull. Soc. Ind. Mulhouse, 1897, 161—231.

THE authors have exhaustively investigated the mordanting properties of the compounds of 19 metals, *viz.*, Cl, Sn, Ce, Pb, Bi, Mn, Hg, Cd, Zn, Cu, Cr, U, Ni, Co, Fe, Al, Y, Zr, Th. The mordants employed were usually the acetate or aceto-nitrate, which were printed on calico in stripes, the printing-mixture consisting of mordant solution thickened with Alsace gum, of such a concentration that 1 litre corresponded to 0.11 of the atomic weight of the metal in grammes. After printing, the mordants were dried, fixed with gaseous ammonia, passed through a chalk bath, and the pieces well washed. A sample of the calico thus printed with the 19 mordants was then dyed with 1 grm. of colour per litre of water, with the addition of chalk or calcium acetate when considered necessary. The dyed patterns were divided into four portions, of which one was immediately dried, a second soaped at 60° C., the third soaped at 60° C. and then exposed to light (the results of exposure will be published later), and the fourth soaped at the boil with 10 grms. of white soap per litre.

Tables are given showing the colour obtained with each of the 66 colouring matters employed and each mordant, also the results of soaping at 60° C. and 100° C. respectively. The following is a list of those colours, which are interesting both on account of the shade obtained and by reason of their fastness to boiling soap:—

Mordant.	Colouring Matter.	Shade.
U.....	Methylene Blue	Very bright deep violet
Zr, Th, Cr.....	Galloxyann	Black-violet
Bi, Y, Zr, Th.....	Ceruleum	Greenish-olive
U.....	Saffranine	Bright deep crimson
Bi.....	Rhodamine	Very bright violet-pink
Cl.....	Citron-Violet	Pink
Zr, Th, Bi, Cu.....	Weld	Yellow
Cl.....	"	Yellow (less fast)
Zr, Th.....	Gamboge Cutch	Cutch brown
Bi.....	Sumach	Rich olive-yellow
Cu.....	"	Mode shade
Zr, Th.....	"	Yellow mode shade
Y, Cu, Ce, Zr, Th.....	Tannin	Mode shades
U.....	Quercitron Bark	Puce
Zr, Th, Bi.....	Persian Berries	Orange-yellow
U.....	"	Bright red-orange
Ni.....	Erica B (Berlin)	Violet-crimson
Ni.....	Acid Ponceau (Durand)	Light orange-red
Mu.....	Bismarck Brown	Orange bistre
Ni.....	Benzo Orange (Bayer)	Red
Ni.....	Conzo G R (Berlin)	Dull red
Ni.....	St. Denis Red (Poirrier)	Light red
Ni.....	Diamond Black (Bayer)	Violet-black
Ni.....	Ponceau 6 R B (Berlin)	Violet-pink
Cl.....	Alizarin R, V, & J.	Reddish-black
U.....	"	Black
Zr.....	"	Dark crimson
Cl.....	Alizarin Black	Bluish-grey
Zr.....	Alizarin Yellow A	Pink (after soaping)
Cr.....	"	Bright yellow
Cu.....	Carbazol Yellow (Badische)	Very deep yellow-olive
Zr, Th, Cl.....	Carbazol Yellow	Orange-yellow
U, Ni, Zn, Cd, Th.....	Methyl Violet B (Badische)	Violet
Al.....	Patent Blue (M. L. & B.)	Bright violet-blue
Ni.....	Azo Green (Bayer)	Green
Sn.....	Alizarin Blue X (Badische)	Red-violet (in acid bath)
Sn.....	Alizarin Green S (Badische)	Violet-grey
U.....	Alizarin Maroon (Badische)	Violet-black
Y, Zr, Th.....	Alizarin Maroon	Puce, or deep violet
Cl, Al, Zr, Th.....	Alizarin Orange	Crimson
Y, Zr, Th.....	Anthracene Brown	Puce
U.....	Quercitron Bark	Olive-yellow
Zr, Th.....	"	"
U.....	Old Fustie	Bright deep wood colour
Y, Zr, Th, Cr.....	Cochineal	Red to red-violet
U.....	Pyronine G (Leonhardt)	Dark crimson
U.....	Benzodavine (Oehler)	Very bright deep orange
Pb.....	Gallein	Blue
Zr.....	"	Deep prune
U, Bi, Zr, Th.....	Pegu Cutch	Wood brown
Sn.....	"	Cutch brown
U.....	Magdala Red	Very deep purple

*Metallic Oxides Acting as Resist for Colouring Matters.*

Resist.	For
Sn.....	Saunders G
".....	Madachite Green
".....	Azo Green
Pb.....	St. Denis Red
".....	St. Denis Red
Cu.....	Diamine Violet
U.....	St. Denis Red
Cu.....	Violet Blue X

In the two final chapters the authors give the constitution of the artificial dyestuffs used in their experiments, and a list of the chief deposits which serve as sources of the rarer metals employed. The prices of certain pure salts of these metals in December 1895 are also given as follows:—

	Francs per Kilo.
Calcium (sulphate).....	100.5
Cerium (acetate).....	25.0
Bismuth (acetate).....	17.5
Uranium (acetate, crystallised) ....	27.5
Yttrium (nitrate).....	500.0
Zirconium (nitrate).....	75.0
Thorium (nitrate).....	355.0

—R. B. B.

## PATENTS.

*Dyeing Cotton and other Vegetable Yarns, Threads, and Fabrics; Impts. in.* Ad. Liebmann and Al. Liebmann, Manchester. Eng. Pat. 21,253, Sept. 25, 1896.

THE authors have discovered that if dyed vegetable fibres are mercerised, or if the colouring matter be added to the mercerising solution itself, the colours become fixed in the fibre. Dyeing and mercerising may be performed simultaneously when the dyestuff to be used is soluble in the mercerising bath. When this is not the case, the goods are impregnated with a solution of the dyestuff, and are then mercerised in the usual way.—I. S.

*Cotton Threads and other Textile Materials, Impts. in the Method of and in Means for Dyeing and Finishing or Dressing.* C. H. Jacob, Lyons, France. Eng. Pat. 23,199, Oct. 22, 1896.

THE two essential features claimed for this invention are the method of preparing a solution of "Hui-Thao" or vegetable gelatin (or "Gelose," as it is also termed), and the means for applying it. 30 litres of glycerin at 28° C. are mixed with 30 litres of water, and 3 kilos. of "Hui-Thao" are dissolved in this at boiling temperature. When solution is complete, and whilst still hot, 200 grms. of zinc sulphate, previously dissolved in water, are added. The yarns are passed in single threads through this solution, thence through eyelets to remove surplus liquor and to smooth down the nap of the yarn, and finally through a heated chamber for drying.—I. S.

*Kiers and like Vessels for Bleaching, Dyeing, and similarly Treating Textile Materials, Yarns, and Fabrics; Impts. in connection with.* E. Makin, jun., Manchester. Eng. Pat. 23,635, Oct. 24, 1896.

THE principal objects of this invention are to enable the bleaching or other liquor to be rapidly and economically heated and freely circulated throughout the materials under treatment. Any convenient kier or vessel is connected at or near the bottom by a pipe, to a series of hollow shells or vessels in the form of cones placed in a suitable furnace flue and arranged in a row, the larger end of the second cone overlapping the small end of the first, but preferably without touching it, and so on; thus leaving spaces between the cones as well as a central passage through them for the gases from the furnace. The hollow cones are fed or supplied with bleaching, dyeing, or other liquor in any convenient manner, and are also connected by a discharge pipe to the upper portion of the kier.—J. S.

*Scouring and Dyeing Hanks of Yarn or Fibrous Materials, Impts. in Apparatus for.* H. Bentley, Bradford. Eng. Pat. 23,718, Oct. 26, 1896.

A RECTANGULAR, movable framework, which can be raised or lowered into a suitable vat, is fitted along the top at one side with a number of sockets geared together and adapted to receive the square ends of sticks similar to those usually employed to support hanks of yarn in vats. The other ends of the sticks are fitted with metal journals (screwed into and capped over the end), which rest in bearings formed in the framework at the other side; and provision is made to confine these journals longitudinally in their bearings, and so keep the other ends in their sockets. A similar arrangement is provided below to receive a bottom set of sticks. The sticks are revolved by means of a shaft fitted at one end of the vat, and geared by means of toothed wheels with the pinions of the sockets.—I. S.

*Mordanting Yarns, Threads, Fabrics, and other Materials composed of Fibres having a Vegetable Origin; Impts. in the Method and Means for.* Ad. Liebmann and W. Kerr, Manchester. Eng. Pat. 23,741, Oct. 26, 1896.

THE metallic oxides to serve as mordants are dissolved, with or without the aid of glycerin, in a strong solution of caustic soda, in which the goods are then mercerised and mordanted in one operation.—I. S.

## VII.—ACIDS, ALKALIS, AND SALTS.

*Glover Tower, Construction of.* H. H. Niefenführ. Chem. Zeit. 21, [68], 664—666.

IN the construction of a sulphuric acid plant, it is not only necessary to consider the suitability of the individual portions of the apparatus for their own particular work, but each part must be studied in its mutual relationship to all the other parts. This is especially true of the Glover tower: and the author thinks that by suitable construction it can be made much more valuable than at present, especially since, in addition to its own particular function, it also acts as a much more intense acid-producing apparatus than the lead chamber itself.

In the sulphuric acid manufacture we have to deal with reactions between gases and vapours, and also of these with liquids. The energy and completeness of these reactions depend upon a suitable composition of the gaseous mixture, the time of reaction, and the nearness of the molecules to one another, that is, to the pressure under which the gases are. The liquids to be considered, are weak and strong vitriol and nitrous vitriol, and they must naturally present as large a surface as possible to the gases, and be maintained a considerable time in contact with these. To obtain a suitable composition of the gases, a correct working of the pyrites burners is essential, since this lies in the closest connection with the draught as the source of the oxygen. The draught at the end of the system does not, however, indicate the working of the individual parts of the plant, and these should be so arranged that an intense and uniform reaction takes place in the rear end of the chamber. For this it is essential that the gas entering the lead chamber should not be diluted, by diffusion, with the less active and partially spent gases resulting in the process.

This is readily managed in a plate-tower system, which, by its symmetrical construction, ensures a uniform movement of the whole gas.

Here is an advantage of the plate-tower over the cone, the dead space in which leads to a lagging behind of the slower-moving molecules. In the lead chamber this dilution cannot be avoided; it is partially lessened by combining several chambers in one system, and thus effecting a space separation of the gases according to the concentration changes. When the space is thus divided between three chambers, a common proportion between the sizes of these is 3:2:1. From observation, the author states that the maximum space should not be allotted to the first chamber; this agrees with the above considerations; but he would not, however, recommend extreme smallness for this chamber. For cross-section, on which the gas velocity mainly depends,

and with this the duration of reaction, the author has found for systems of 3,000 cb. m. a chamber cross-section of 45—50 sq. m. to be most advantageous, and larger or smaller systems should be constructed proportional to this standard. He also deems it advisable to diminish the height and width of the individual chambers in proportion to the diminution of absolute gas volume.

Connected with energetic and uniform production in the first chamber, is the maintenance of a definite time of reaction and pressure, and care must be taken to diminish neither this nor the correct working of the burners in the introduction of the Glover tower. The draught must be diminished as little as possible. For this the burners should lie as deep as possible, and the roof of the chamber following the Glover should be higher than that of the latter. Attention must be paid to the tower packing, to obtain with the least loss of draught the most intimate contact between the gases and liquid. The loss of draught is less, the greater the cross-section of the tower, but since in wide towers the contact of gas with liquid is incomplete, the author recommends the use of two towers lying parallel. For a 3,000 cb. m. system the base area of these should be  $2.75 \times 2.75$  m. (measured from lead to lead), and it is important, that two equally long and wide pipes should connect these with the burners, and a second pair with the chamber. The inlets to the chamber are so arranged that each is equally distant from the chamber outlet situated on the opposite wall. The increase in cross-section allows of diminished height; this simplifies the placing of the chamber at a higher level than the tower. The lesser height and greater section favour a retardation in the gas velocity and increase the contact of the gas with the nitrous vitriol, that is, the reactions in the tower. A still greater effect is produced by increasing the time during which the nitrous vitriol remains in the tower, which also allows of a diminution in height. That this is correct has been shown in the use of Lunge-Rohrmann plates as tower packing. The Administration of Mines of Buehweiler, with the unsuitable burner gas obtained from gas-purifying residues, performed 80 per cent. of the total deutification in a plate-tower only 1.75 m. high; the daily production being 4,000 kilos. of  $\text{H}_2\text{SO}_4$ . At works in Copenhagen and Japan the effects of the Glover towers have been increased by the introduction of plate layers.

Neither the material nor the size of the holes in the ordinary Lunge-Rohrmann plates are suitable for Glover towers; but, recognising the value of the plate idea, the author has altered these by substituting for the material the ordinary acid-proof firebrick, and while retaining the network arrangement of the holes, altering the canals around these so as to maintain in circulation the largest possible quantity of acid. A Glover tower of 4 sq. m. section would require 128 stones of the modified pattern for each layer, and these would hold about  $18\frac{1}{2}$  litres of acid, or  $\frac{1}{2}$  litre of liquid surrounding each gas passage.

Regarding the possibility of a deposit forming in these canals, the author points out that, according to his own experience and that of others, the main bulk of fine dust and condensable matter in the burner gas always settles out in the lower layers of the Glover filling, that is, where the gases first come into contact with the acid. Slimy deposits from the packing are prevented by the movement of the vitriol, and the removal of crusts would be effected by allowing the periodical flow of a strong stream of acid for a few minutes, as is done with the Glover at present. The author therefore recommends that the lowest three or four layers should consist of a network of the ordinary stones, and for the more ready removal of obstructions, he separates these layers from the upper and succeeding ones by constructing these latter upon a special framework so arranged as to leave a space between the two groups of packing material. Through an opening in the side of the tower, closed during the manufacture, with stone, it is an easy matter to remove the blocked lower layers and replace with new packing. By this means the process interruption is diminished, and loss of packing material reduced. The total height of a Glover tower containing 18 layers and the above space, is only 6.15 m., whilst a tower with the same number of the known network rows would be 7.75 m. high.

For larger systems this difference in height becomes still greater, and for a plant of 5,000 cb. m. might easily reach 3 m.—J. T. C.

*Persulphuric Acid; Electrolytic Formation of.*

P. Richarz. Ber. 30, [14], 1826—1827.

THE formation of persulphuric acid, as the result of the association of two  $\text{HSO}_4$  ions (referred to by Nernst, Ber. 30, [12], 1826), was observed and thus explained in 1881 by the author (Wiedemann's Ann. 24, 183), who determined all the conditions of its formation. In the same paper and a later one (Wied. Ann. 31, 912), he showed that the hydrogen peroxide formed at the same time resulted from a secondary action of the persulphuric acid. Later researches have added nothing new to these results.

Helmholtz (Wied. 11, 737), in 1880, observed the sudden increase of current as the E.M.F. of 1.08 volts is overstepped, Glaser's observation of which was described by Nernst (*loc. cit.*). The author and Lommes (Zeits. f. Physik. Chem. 20, 115) have confirmed this, and have shown that at the same point, the formation at the cathode of hydrogen peroxide (from the reduction of dissolved oxygen) begins.—J. T. D.

*Plumbates, Alkaline Earth  $[\text{XPbO}_3]$ ; Manufacture and Properties of.* G. Kassner. Rev. Chim. Ind. 1897, 8, 227.

THE plumbates of the alkaline earths are produced by heating an intimate mixture of litharge with a small excess of the carbonate of the desired base for an hour or so in a current of air and, preferably, steam, in any kind of furnace which will allow of a temperature of 600 to 1,000° C. being maintained. They may be employed as oxidising agents by treatment with (1) water under pressure, (2) alkali carbonates, or (3) mineral acids, in order to yield lead peroxide; or they may be heated to dull redness in a current of carbonic acid gas, to produce free oxygen. They are practically insoluble in water, and their colour deepens, with the increasing atomic weight of the basic metal, from the yellow of the calcium compound to the black of the barium salt. Calcium plumbate in particular varies in its activity according to the temperature at which it is made; and if it has not been heated above 800° C., it is readily powdered, decomposes alkali bicarbonate solutions in the cold, caustic alkalis at the boiling point, forms a hydrate with water on standing, and gives off oxygen in an atmosphere of  $\text{CO}_2$  at a low red heat. If the substance has been formed at or above 950° C., it possesses none of these properties; but they may be restored to it by heating under water at a pressure of several atmospheres. In order to ensure the mass being of uniform composition, it should be stirred at intervals in the furnace, or it may be advisably mixed with 5 or 10 per cent. of combustible or volatile matter, such as sawdust or ammonium carbonate, so as to render it more porous. The presence of moisture is rather an advantage than otherwise.

Depending on the facts that they are insoluble and do not evolve gaseous products, these plumbates are indicated as suitable for many industrial purposes. They may be employed to replace the chlorate and part of the binding material in lucifer matches and coloured fires, and the articles are thus rendered odourless. In electric accumulators they yield a very porous coating, and the insolubility of the sulphate resulting from the action of the acid augments the cohesion of the covering. They form good filtering material for crude spirit, their basic nature determining the removal of the impurities, including amyl alcohol, especially if the liquid be slightly acidified with sulphuric acid before treatment. In the manufacture of lead or calcium glass, their use confers the advantage of increased facility in the combination of lime with the silica, since it is not necessary first to expel carbonic acid, as would be the case had chalk been employed, as it usually is. The plumbates can also, it is said, be employed in the preparation of potassium ferricyanide and the utilisation of this salt in a continuous process of bleaching without chlorine.—F. H. L.

PATENTS.

*Chlorine Gas, Impts. in Pumping Apparatus for, and the like.* P. Jensen, London. From H. Cappelen and D. Cappelen, Gjemsø Kloster, Skien, Norway. Eng. Pat. 20,423, Sept. 15, 1896.

THE pump cylinder is of cast iron, lead-lined internally. The plunger is of wood, as well as the washer to the stuffing box, which is lined with wool. The valves and their seats are also of wood, the casings to the valves being of lead.—E. S.

*Sulphuric Acid, Improved Method of and Apparatus for Evaporating.* M. Schwab, Manchester. Eng. Pat. 22,512, Oct. 10, 1896.

THE acid to be concentrated is run into the uppermost of a series of shallow vessels arranged on an incline, each vessel being supported on an iron tray bedded in seatings in the side walls of the run, in a chamber heated directly from a fireplace in front, which chamber is thus separated into two flues (between which there is no passage), the flue below for the heating gases, and that above for the acid vapours, which are taken off near the top. The dishes are of flattened V-shape, with plane bases inclined upwards from a vertical rear wall to a curved lip at the discharging end. Above each dish, and supported by the side walls of the run, so as to form a roof for the evaporation chamber, a removable fire-clay plate or slab is fitted; access is also provided for by gas-tight doors in the sides of the chamber. An iron pipe, communicating with the external atmosphere, traverses the heating flue, and is connected in front to a projecting valved pipe, recurved inwards to enter the lower part of the evaporating chamber or flue, to which it conveys a current of heated air, assisting the evaporation. The advantage of using shallow or flat evaporating dishes containing but a small volume of acid at a time, is that no bumping, and so no considerable vibration, is caused during the boiling process, and hence no deterioration, such as cracking of the apparatus, with consequent leakage, and escape of acid fumes into the chimney, can take place.

—E. S.

*Bleaching Compounds, Impts. in the Manufacture of.* J. W. Chenhall, Torquay, Devon. Eng. Pat. 22,792, Oct. 14, 1896.

SODIUM or potassium carbonate, bicarbonate or hydroxide, in strong cold solution, is saturated with chlorine, and finely divided carbonate or bicarbonate of the alkali used, is slowly added with stirring until the liquid thickens to the consistency of dough. The mass is then left to harden.

—E. S.

*Sulphuric and other Acids, Impts. in Apparatus for Concentrating.* E. Dyson, Manchester. Eng. Pat. 27,769, Dec. 5, 1896.

THIS invention relates to improvements in Eng. Pat. 17,699, 1893 (this Journal, 1894, 1959). The apparatus consists of a double row of stepped retorts, overflowing by lips one into the other, and each connected by a tube from its top to an inclined condensing pipe on one side, which receives the vapours. The retorts are enclosed below in a flue, the bottom or floor of which, according to the present improvements, is constructed of arched blocks, flat and horizontal on the top surface, on which the retorts rest, and are arranged in steps. The blocks are perforated to admit of the passage of heated gases from the chamber below. Each retort is provided with a loose division-plate extending from near the top to near the bottom, a groove being formed in the sides to admit of asbestos packing, the plate being held in position by ledges. In addition to, or instead of the division-plate, a distributing tube or fountain may be placed so as to receive the liquor flowing from one vessel and deliver it at or near the bottom of the next. The tubes are constructed with branches or outlets so placed as to prevent obstruction by sediment. A perforated plate is attached near the upper edge of the distributing tube, about on a level with the spout. Violent ebullition or splashing of the acid is thus prevented. Three or more of the lower retorts are cut off from the heating flue by a

division-plate, in order that the acid in them may cool gradually before it passes to the cooling receiver.—E. S.

*Alkaline Cyanides, Method of Drying.* J. D. Gilnour, Lenoxtown, N. B. Eng. Pat. 29,922, Dec. 29, 1896.

Air, heated preferably by the condensed water from steam, as the temperature must not exceed that of boiling water, is passed over the cyanide to be dried, then through a condenser, and, when deprived of moisture, is again passed over the cyanide, and so on repeatedly. The continuous use of the same portion of air is to prevent the introduction of an injurious quantity of carbonic acid, and consequent decomposition of the cyanide.—E. S.

*Metallic Chlorides, such as those produced from Sulphide Ores; Impts. in the Treatment of.* E. T. Turner, Adelaide, South Australia. Eng. Pat. 17,834, July 29, 1897.

This invention relates to improvements on Eng. Pat. 15,749, 1896 (this Journal, 1896, 741), according to which sulphide ores of zinc and lead containing small proportions of gold, silver, and other metals, were subjected to the action of gaseous and aqueous hydrochloric acid to obtain chlorides, which, after fusion, were treated by lixiviation and precipitation processes, the hydrochloric acid being regenerated. According to the process now described, the chlorides obtained are electrolysed while molten, to separate gold, silver, and lead. The residue of zinc, iron, and manganese chlorides is heated in a retort in which a partial vacuum is obtained by means of a steam jet. The zinc chloride volatilised, is decomposed by the steam into zinc oxide and hydrochloric acid, which latter is condensed for re-use. The iron and manganese chlorides remaining undecomposed are treated with steam in revolving calciners to obtain the oxides and hydrochloric acid. Or, alternatively, the iron and manganese chlorides may be decomposed by sulphur dioxide and steam in vertical cylinders.—E. S.

*Nitric Acid, Impts. in Apparatus for Converting Nitric Peroxide into.* O. Guttman, London. Eng. Pat. 18,189, Aug. 4, 1897.

The object of the apparatus is to bring the whole of the acid formed into contact with the ascending unconverted and uncondensed gases. The nitric peroxide gases pass from an ordinary denitrification apparatus into an earthenware receiver filled with coke, broken glass, or balls, as described in Eng. Pat. 14,774, 1896 (this Journal, 1896, 700), whence they are drawn by a compressed-air ejector into two or more vertical coke-charged towers, down which water trickles. The liquid nitric acid thus formed runs into a distributing tank, and the gaseous portion passes from near the top of the towers to a Guttman-Rohrmann water-cooled battery. The distributing tank has a number of sockets, screened internally, through tubes connected, to which the acid flows to the arched tops of the condensing tubes. A portion of the acid also flows to the earthenware receiver first mentioned. The gases remaining unabsorbed in the condensing tubes, are led into another condensing tower, and return as liquid acid. From the condensing apparatus the acid flows into a collecting vessel, which also receives the acid formed in the first-named receiver.—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

*Flue-Dust from Glassworks, The Composition and Origin of.* O. Grosse. Chem. Ind. 1897, 20, 430—434.

The author has analysed the flue-dusts from three glassworks using the Siemens regenerative system. In each case two samples were taken: the one close to the furnace, and therefore deposited at a high temperature; the other from a point near the chimney, deposited at a lower temperature.

*1. Fürstenberg Works.*—The two dusts were readily distinguishable by their colour. The sample collected near the furnace was pure white in colour, uniform, and distinctly crystalline in structure (prisms). It was completely homogeneous and coherent, and broke with a gritty sound in an agate mortar. Chemical analysis showed it to be a mixture of silicates with free silica.

The second sample, deposited at the lower temperature, was of a dark reddish-brown colour. It consisted, like the preceding, of coherent, perceptible hard crystals. It was not completely homogeneous, hard particles of oxide of iron being found in it. The first contained 96.7, the second 97.6 per cent. of silica.

*II. Josephine Works.*—The two samples differed very markedly from those of the Fürstenberg works. With the exception of a small residue of quartz-sand from the walls of the flue, both consisted of an extremely fine powder showing no tendency to agglomerate, and exhibiting under the microscope no trace of crystalline structure. Both samples were light grey in colour. They exhibited a reddish tinge, and the sample taken furthest from the furnace was less dark in colour than that collected nearer to it. This is due to the different proportion of sand containing iron, which was present in the two cases. Both were soluble in dilute warm hydrochloric acid of sp. gr. 1.01; only the admixed sand remained behind.

*III. Wiesener Works.*—These dusts, in addition to sand, contained non-homogeneous particles of indistinct crystalline structure, some yellowish and others light green in colour. Like the Josephine dusts they were soluble in dilute hydrochloric acid, but they differed in colour, the dust from near the furnace being ochre yellow, the other deep black, owing to admixed finely divided carbon.

The author indicates three possibilities for the formation of these dusts: the particles are either carried mechanically forward from the furnace mixture by the gaseous current; or they are due to volatilisation occurring at the high temperature of the furnace, the volatilised substances depositing in the cooler portions of the system; or both these processes may occur simultaneously. In either case the material deposited in the flues is subjected to the further action of the gases evolved from the fused mass.

The author inclines to the view that the dust is due to sublimation. In support of this he refers to the well-known volatilisation of glass galls, to the crystalline nature of certain of the dusts, and to the analyses given in the original paper, which only show  $\text{SiO}_2$ ,  $\text{CaO}$ ,  $\text{PbO}$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ , and alkali, with arsenic and sulphuric acids in estimable quantity;  $\text{Cr}_2\text{O}_3$  and  $\text{Mn}_2\text{O}_3$  were either entirely absent or only present in traces in the dust, although at the Josephine and Wiesener works, relatively large quantities of each were added to the melt. The author points out that the earths present in the dust, form chlorides volatile at relatively moderate temperatures—he gives an experiment to prove the volatility of  $\text{CaCl}_2$ —whilst chromium chloride decomposes to oxide on heating in air, and manganese chloride is only volatile at very high temperatures.

The formation of chlorides in the melt has its origin in the alkali chlorides present as impurities in the sodium or potassium carbonates or sulphate used in the manufacture. These alkali chlorides react either to produce hydrochloric acid with the silica and water-vapour, or else by direct substitution—

Other silicates will react similarly to the calcium silicate.

—J. T. C.

*Glass, Elasticity of: Its Dependence on Temperature.* A. Winkelmann. Wied. Ann. 61, 105; Chem. Zeit. Rep. 21, [59], 153.

ELASTICITY is usually regarded as an additive property, that of a mixture being the sum of a number of terms, each made up of two factors: a constant depending on the nature of the constituent considered, and the proportionate mass of that constituent. The author's experiments do not confirm this, and in the case of glasses it is only approximately true for the members of a group of similar composition. The dependence of elasticity on temperature has been examined up to the softening point. The simultaneous addition of sodium and potassium oxides to a glass, increases, but that of boric anhydride, decreases the variability with temperature. In all cases, however, when the expansion is taken into account, the variation of elasticity with temperature is slight. The coefficient of elasticity is uniformly greater after heating than before.—J. T. D.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Hydraulic Cements, Action of Sea-Water upon.* W. Michaelis. *Proc. Inst. Civil Eng.* 1896-97, 129, Part III., 1—11.

PORTLAND and other hydraulic cements, containing excess of lime, segregate such excess as hydrate during the hardening process, so that, in the case of Portland cement, the hardened mass becomes completely permeated with crystals of calcium hydrate. When the mortar hardens in sea-water, the excess of lime is converted, in the first instance, into sulphate, and ultimately into silicate; but hand in hand with the formation of calcium sulphate goes the production of calcium aluminate-sulphate requiring certainly 30, and probably 60, equivalents of water for its crystallisation, and resulting in such enormous increase of volume that cohesion is destroyed. The true Roman cements, containing 1 part by weight of silicate to 1.1 or 1.2 parts of lime, form more stable compounds, without unsaturated residues, and therefore from a chemical point of view form the best hydraulic mortars. They resist the action of sea-water well, because the much smaller proportion of the double salt with alumina which is formed, finds sufficient space for expansion in the pores of the mortar. Such cements, however, are burnt at so low a temperature that they are deficient in density, so that mortars made with them shrink on exposure to the air, through the evaporation of the water which they have absorbed.

Portland cement, having been burnt at a higher temperature than Roman cement, is denser, but is defective from the chemical point of view, owing to the excess of lime already referred to. Hydraulic limes, such as those of Teil, bear a close resemblance to Roman cements, but are even looser still in texture. They contain, however, but little alumina, and the chief increase in volume they sustain is due to the crystallisation of calcium sulphate—not to the double salt above referred to.

The author's experiments show that these Portland cements richest in lime offer the least resistance to sea-water, from which it follows that for marine work the addition of lime or of highly calcareous cements to Portland cement is unsuitable. Moreover, modern Portland cements of high strength, but rich in lime, are less suitable for this class of work than the older cements containing less lime.

Mortars containing free caustic lime are very unstable. Great internal strains are produced, so that expansion and cracking may go on for years. This, however, may be remedied by the addition of sufficient hydraulic silica or alumina to form more stable compounds with the lime which remains or becomes free during the hardening process.

The addition of trass or of an efficient puzzuolana to Portland or other hydraulic cements containing excess of lime, can increase the strength of the mortars twice or three times, and render them stable in sea-water.

From a Portland cement with an average amount of lime, about 53 per cent. of calcium hydrate would be segregated. It is, therefore, advisable to add at least 125 parts by weight of trass to 100 parts of cement. The more lime present, the more trass is required.

In further experiments with various mortars, the author used artificial sea-water and solutions of calcium, magnesium, and sodium sulphates. One of the mixtures which withstood the action of calcium sulphate best was Teil lime,

mixed with 5 parts of standard sand; all mixtures, however, containing hydraulic silica, either as hydrate or in the form of trass or burnt kaolin, were only slightly acted upon by either calcium or magnesium sulphate, and remained intact after the lapse of two years. Near Portland cement mixtures, without the addition of hydraulic substances, soon disintegrated, especially when rich in alumina.

Hydraulic cements which contain more lime than is required to form stable hydrosilicates and hydro-aluminates, should not be used for marine work unless improved by the addition of substances such as those named. The author suggests that it would be preferable for the manufacturer of the cement, rather than for the consumer, to add the necessary quantity of puzzuolana or trass, as the proportion to be added would vary with the composition of the cement, which would be best known to the manufacturer.—H. H. B. S.

*Blast-Furnace Slag that has been treated with Nitric Acid as an Addition to Hydraulic Cement.* A. D. Elbers. *Eng. and Mining J.* 1897, 64, [13], 364, and [16], 454. (See also this Journal, 1897, 680 and 800.)

IN the tests for tensile strength, the briquettes had broken near the middle of the stem; two test-pieces for the crushing experiments were prepared from each fractured briquette, in the following manner. The stems of the broken pieces were ground until one piece measured 1½ in. in length—measuring through the centre of the stem to the top of the head—and its counterpart, 1½ in. in length. The superficial area of the pieces thus prepared, averaged about 2 sq. in., each piece differing from its counterpart about one-sixteenth part in volume. The following results were obtained:—

### A.—Tests with High-Class Portland Cement.

Composition of Test Piece.	Tensile Strength per Square Inch after 16 to 18 Days.	Resistance to Crushing per Total Surface Area (about 2 Sq. In.) after 128 to 130 Days.
	Lb.	Lb.
Neat Cement .....	565	12,000—15,150
" .....	526	13,200—15,000
Cement, 80 per cent.; prepared slag, 20 per cent. ....	496	11,180—12,750
Cement, 60 per cent.; prepared slag, 40 per cent. ....	305	11,870—12,910

### B.—Tests with an Inferior Portland Cement.

Composition of Test Piece.	Tensile Strength per Square Inch after 19 Days.	Resistance to Crushing per Total Surface Area (about 2 Sq. in.) after 131 Days.
	Lb.	Lb.
Neat Cement .....	310	6,100—6,400
Cement, 60 per cent.; prepared slag, 40 per cent. ....	335	6,300—6,650
Cement, 40 per cent.; prepared slag, 60 per cent. ....	310	6,800—7,350

*Note.*—The resistance to crushing is stated separately for each piece of the broken briquette, the first number denoting the resistance of the shorter piece, and the second number, the resistance of its counterpart.

The test pieces prepared from the briquette made by casting the "slurried" mixture into the mould, and composed of 90 per cent. of high-class Portland cement and 10 per cent. of the prepared slag, with 30 per cent. of water added, gave the following results:—Tensile strain per square inch after 17 days (as previously reported), 350 lb.; resistance to crushing of the shorter piece, 9,450 lb.; resistance to crushing of the larger piece, 10,770 lb.

It is stated that cement "pats" containing slag that has been treated with nitric acid, after having been sufficiently long under water to become properly hardened, and then treated with weak solutions of strong acids, evolve very little, if any, more sulphuretted hydrogen than neat cement under the same conditions.

With regard to mixtures of cement, prepared slag, and sand, it was found that unfavourable results were apt to be obtained at first, but that after some time, especially if kept under water, the strength of the cement mixtures containing prepared slag and sand, increased more rapidly than that of the mixtures containing sand alone. The following table gives the results of tests made with an inferior Portland cement (the same as used for the tests given in Table B). The briquettes were tested for tensile strength on May 26th, when 19 days old; the resulting halves were kept in a dry place until September 15th, kept under water for 20 days, and crushed on October 5th.

Composition of Mixture.	Tensile Strength in Pounds per Sq. In. after 19 Days.	Resistance to Crushing in Pounds for about 2 Sq. In.
1 part of neat cement and 3 parts of sand.	160	2,575-2,820
* cement, $\frac{1}{2}$ slag and 3 parts of sand.	90	2,340-2,675

On comparing the relative results for tensile strength of the neat cement (see Table B) and the mixture of cement and sand, the author considers that if the average of 5 or 10 tests of the former had been taken, a higher result would have been obtained. On the other hand, the ratio between the resistance to crushing and the tensile strength of the mixture of cement, prepared slag, and sand, seems to indicate that the average of five or ten tests would have shown a much higher tensile strength than 90 lb. to the square inch.—A. S.

#### PATENTS.

*Kilns for Burning Bricks, Tiles, Lime, and the like; Impts. in.* F. D. T. Lehmann and P. N. Kohlsaat, both of Chicago. Eng. Pat. 14,673, July 2, 1896.

This invention consists of a brick kiln of the continuous type, but constructed with movable instead of permanent walls. The bricks are set up in the open air and the walls built round them, and similarly, after the bricks are burnt, the walls are taken down and the bricks exposed to the air. There are 10 chambers, and each day the one which has been fired the longest is taken down and set up with fresh bricks at the other end. The walls, floor, and covering are of fire proof tiles and the chimney of sheet iron. The flue is laid underground, beneath the kiln, and has connections, provided with dampers, leading into each of the chambers, but it can be taken up and relaid, as occasion requires, to suit the alterations in the position of the chambers. For the same reason the chimney is mounted upon wheels and runs upon a track.—H. H. B. S.

*Fire Bricks and Fire-Proof Mortar. Impts. in the Manufacture of.* A. C. Ponton, Bedford. Eng. Pat. 21,781, Nov. 2, 1896.

ONE ton of finely-ground burnt flints, with or without the addition of fine sand, is mixed with about 20 gallons of silicate of soda or potash and 3 or 4 cwt. of damp finely-cut fibrous material, such as hay or straw. The mixture is moulded into bricks, which are dried and burnt at a sufficient temperature to volatilise the soda or potash and to consolidate the silica.—H. H. B. S.

*Finely Pulverised Substances, for Use in the Production of Portland Cement, Pigments, and the like; Impts. in the Manufacture of.* R. Hunter, Glasgow. Eng. Pat. 24,711, Nov. 5, 1896.

The ingredients are crushed in a stone breaker and then, by an arrangement of elevators, successively conveyed to and passed through a pan mill, mill stones, and a revolving

screen fitted with blades, the powder being finally received in a chamber, from which it can be drawn off for use as required.—H. H. B. S.

*Bricks, Tiles, and the like; Impts. in the Manufacture of.* A. W. Fludder, Great Shelford, Cambridgeshire, and G. H. Innes, Hitchin, Herts. Eng. Pat. 25,225, Nov. 10, 1896.

DRIED and ground chalk, marl, and sand, or ground flint, are mixed with the requisite proportion of water and kneaded into a semi-plastic mass, which is then moulded into shape and burnt in the usual way. A little blue gault is sometimes added, which enables the burning to be carried out at a lower temperature.—H. H. B. S.

*Impregnating Fibrous Substances, such as Wood, Peat, or the like; An Improved Process for.* W. P. Thompson, London. From F. Hasselmann, Munich, Germany. Eng. Pat. 25,240, Nov. 10, 1896.

THE object of this invention is the rendering of wood and other fibrous substances proof against destruction by fire, damp, insects, &c. The wood is successively impregnated with two solutions, which combine to form a solid substance in its pores, after replacing the easily decomposable saps. The following combinations are proposed:—Copperas and chloride of calcium; chloride of zinc and caustic baryta; copperas and caustic baryta; chloride of zinc and chloride of calcium; caustic baryta and chloride of calcium. The impregnation may be carried out either by soaking in the cold or by boiling, or by pumping out the air and sap from the wood, so as to facilitate the admission of the fluid into the very interior.—H. H. B. S.

*Tight Joints, A New or Improved Composition for Making, and similar Purposes.* H. Redhead, Newcastle-on-Tyne. Eng. Pat. 26,673, Nov. 24, 1896.

THE composition is intended to be used in place of red or white lead for making tight joints in steam, water, gas, and other fittings. It is compounded of Portland, Roman, or other cement; Venetian red or brick dust; boiled linseed or other oil; litharge; and chalk or whiting.—H. H. B. S.

*Grinding and Polishing Material, Artificial, and Grinding and Polishing Tools, Impts. in the Manufacture of.* W. von Floryanowicz, Warsaw. Eng. Pat. 6793, March 15, 1897.

THE patentee produces a powder, equal in hardness to emery, and applicable either as a grinding or polishing powder or for further manufacture into polishing wheels, grindstones, &c. Fire-clay is mixed into a paste with water, the mass dried, and burnt at a temperature of about 1,200° to 1,300° C. If the fire-clay does not fuse at this temperature, about 10 per cent. of felspar or 2 per cent. of burnt lime is added. The burnt clay is ground and sifted. To make grindstones, &c., 40 per cent. of the powder is mixed with 45 per cent. of ground fire-clay and 15 per cent. of manganese, the mixture moistened with water, pressed into shape, dried, and burnt at about 800° C.—H. H. B. S.

#### X.—METALLURGY.

*Gold Field, Canada's Newest.* J. T. Donald. Eng. and Mining J. 1897, 64, [13], 369.

AURIFEROUS quartz veins, from 8 in. to 2 ft. and 3 ft. in width, have been discovered on the north shore of Lake Superior in the vicinity of the Michipicoten River. The samples which have been tested have yielded high results.—A. S.

*Hand-Jig, An Experimental.* P. Buttgenbach. Eng. and Mining J. 1897, 64, [11], 305.

THE author uses the following apparatus for making preliminary tests, previous to treating the ore on a large scale, and also when only a small sample of ore is available for examination. A glass cylinder B, open at both ends, is fixed inside an outer glass vessel A, by means of an airtight india-rubber stopper C. Through C passes a copper tube D, which is connected outside the vessel to an air-ball F.

Within the vessel, the tube D is connected to a hollow copper ring G, which encircles the inner glass cylinder. This ring is perforated on its upper side with small holes, increasing in size as they lie further from the junction with the tube D. The lower part of the inner glass cylinder is provided with a projecting flange L, to which a copper wire screen is fastened by means of a clamp ring K. The ring

P, carrying the screen, has an india-rubber ring fixed on the face nearest the glass, in order to insure a tight joint. The apparatus is filled about three parts full of water and the ore to be treated is placed in the inner vessel. By squeezing the air-ball with the hand, the air between the two vessels is evenly compressed and forces up the water, as well as the ore, in the inner vessel. On continuing this action, the separation of the minerals according to their specific gravity is effected, just as in the ordinary piston-jigs. When the separation is complete, the air ball is disconnected, and the inner vessel, together with the india-rubber stopper, is withdrawn in a vertical position and allowed to drain. A strong wadding is then rammed into the vessel until it is in good contact with the ore, the vessel is inverted, and after removing the clamp and screen, the ore is forced out in layers by pressing on the wadding, and each layer cut off. For jiggling "through the bed," a screen is used having meshes of 1 mm. and a bed of shot, 2-4 mm. in diameter. The ore of high specific gravity glides through the spaces between the single shot, without it being necessary to force the stroke to such an extent, that the latter is moved from its position. A considerable quantity of light tailings passes through the screen at first, but after a few minutes, nothing but heavy matter will pass, and when this is observed to be the case, the mixed product deposited previously, is taken out and passed through the apparatus again.

For separating very fine material, below, say,  $\frac{1}{2}$  mm., the author employs the German "Handsiebertrog," which acts like a small percussion table.

When working with a small jig of the kind described above, the author has frequently used a saturated solution of beryllate of cadmium (sp. gr. 3.3) instead of water, and has in this manner been able to separate minerals having a specific gravity of more than 3.3, but which would not separate with water, owing to the specific gravities of the different constituents being too near together.—A. S.

**Cyanide Process, Limitation of the.** P. Argall. Eng. and Mining J. 1897, 64, [10], 278.

It is stated that the cyanide process is inapplicable in the case of oxidised ores, in which the gold occurs partly in a coarse state, unless the cyaniding is preceded or followed by amalgamation. Copper ores are also unsuitable for cyanide treatment, even with dilute solutions, as the copper which dissolves, accumulates, and is finally deposited on the zinc in the precipitating boxes. Skey found that a 0.03 per

cent. cyanide solution, after standing for one hour in contact with crushed and thoroughly washed samples of chalcocopyrite and copper glance, contained a perceptible quantity of copper cyanide and traces of sulphur and oxidised sulphur compounds. Sulphide of antimony is also soluble in cyanide solutions. With regard to the action of sulphides, Skey found that a 1 per cent. solution of pure cyanide dissolved a given weight of gold in 10 minutes, but on the addition of 1 100,000th part of sulphur (as a sulphide) it required two hours to dissolve the same weight of gold. The author, however, considers that the presence of minute quantities of alkaline sulphides is not seriously injurious in the practical application of the cyanide process. If the sulphur of a soluble mineral combines with the cyanogen, it does not interfere with the solution of the gold; for instance, galena, though soluble is usually quite amenable to cyanide treatment. Zinc blende and pyrites are practically insoluble in cyanide solutions.

It is stated that a large consumption of cyanide—which may be due to the presence of free acid in the ore, of acid or basic salts, or to the ore being easily soluble in the solution—is invariably accompanied by a low extraction of gold. —A. S.

**Cyanide Mill Solutions.** P. Argall. Eng. and Mining J. 1897, 64, [9], 216.

The following table shows the changes which take place in ordinary mill solutions where zinc is used as a precipitant. The solution was originally made from pure potassium cyanide, and its strength was maintained by the addition of pure cyanide from time to time as occasion demanded:—

	After 6 months' continuous use, during which time the solution passed through 11,000 Tons of Ore.		After 13 months' continuous use, during which time the solution passed through 26,000 Tons of Ore.	
	Before Precipitation.	After Precipitation.	Before Precipitation.	After Precipitation.
KCN .....	Per Cent. 0.501	Per Cent. 0.491	Per Cent. 0.505	Per Cent. 0.505
HCN .....	0.061	0.079	0.017	0.021
Total simple cyanides.	1.302	1.335	1.470	1.445
K <sub>2</sub> Fe(CN) <sub>6</sub> .....	0.008	0.117	0.018	0.026
K <sub>2</sub> CNS .....	0.212	0.207	0.058	0.057
Zn .....	0.316	0.390	0.368	0.388
CaO .....	0.085	0.082	0.172	0.172
Gold in ounces.	1.150	0.007	1.810	0.030

There was no material change in this solution after 18 months' continuous use. Zinc does not accumulate in the solution, as the greater part of that which is dissolved in the precipitating boxes is precipitated on the ore charges in the leaching tanks; zinc also separates out in the form of insoluble ferrocyanide, and as sulphide from the action of alkali sulphides, which are usually present in small quantities.—A. S.

**Alloys, New.** F. J. Davis. Eng. and Mining J. 1897, 64, [9], 249.

MANGANESE bronze, free from iron, may be prepared by using a rich alloy of copper and manganese, in the place of the ferromanganese usually employed. An alloy thus prepared, and suitable for gun-wheels, propellers, and mining machinery, had the following composition:—Copper, 53 per cent.; zinc, 42 per cent.; manganese, 3.75 per cent.; aluminium, 1.25 per cent. The absence of iron permits the use of the large proportion of zinc, without risk of rendering the metal brittle. An alloy of the following composition: copper, 67.25 per cent.; manganese, 18.5 per cent.; zinc, 13 per cent.; and aluminium, 1.25 per cent., proved an excellent substitute for German silver, being quite as strong and making better castings, while it is less liable to corrosion. Its electrical resistance is four times as great as that of German silver. The small percentage of aluminium

in the alloys described above, was added to overcome the difficulty of obtaining sound castings.—A. S.

*Iron and Copper, Browning of.* Illustr. Zeits. für Blechindustr. 26, [38], 1314.

THE (copper) articles, heated to redness and cleaned, are coated with a pulpy mixture of equal parts of verdigris and coleothar ( $\text{Fe}_2\text{O}_3$ ) in vinegar, then heated to redness again, and quickly rinsed in copper acetate solution. Another (dark) shade is obtained by the application of a mixture of powdered ferric oxide and spirit, the article being heated over an open fire, rinsed, and polished with a soft brush. For lighter shades the following mixture is used:—Copper acetate, 2 parts; vermilion, 2; sal ammoniac, 5; alum, 5 parts, in vinegar.

Iron gun-barrels are browned by a mixture of antimony chloride, 2 parts; ferric chloride crystals, 2; gallic acid, 1; water, 4 parts. After drying for about 12 hours in a warm place, the barrels are rubbed over with a woollen cloth and polished with olive oil and wax. Other mixtures suitable for the purpose are: equal parts of antimony trichloride, olive oil, and silver nitrate in 500 parts of water; also, copper sulphate, 54 parts; spirit, 26; nitric acid, 14; iron filings, 3; and water, 200 parts. Cleanliness and freedom from grease are essential to successful results.—C. S.

*Iron, Thermo-Chemical Study of the Refining of.* H. Pontbrière. Iron and Steel Institute, Autumn Meeting, 1897.

IN this paper an analysis of white iron is taken, and its ultimate composition worked out by assuming the various proportions in which the non-metallic impurities combine with the metals present. The heat produced in the many combustions and changes which take place during their removal in the process of refining is then calculated and expressed in calories for each reaction. The following table is then obtained showing for each constituent the heat of combustion per 1,000 grammes, together with the relative proportions of the same carried off by gases and left in the bath. No account is taken of the heat lost by solid matters ejected or volatilised from the converter owing to the difficulty in approximating to their value. The heat radiated from the converter is not allowed for, but may be taken as a constant proportion to be deducted from the figures given, so that their relative values will remain the same.

bustion chamber. By the above means a high temperature is obtained suitable for welding, puddling, and smelting operations.—A. W.

*Separation of Slime, Gas, or other Fluid from Bodies [Ores, &c.] containing or mingled with the Same, Impts. in or relating to the.* W. A. Koeneman, Washington Street, Chicago, U.S.A. Eng. Pat. 20,299, Sept. 14, 1896.

THE material to be treated is fed into a centrifugal strainer, which consists of two concentric perforated shells and an intermediate layer of felt, &c. The liquid, &c. separated by the strainer falls into a hopper, and is discharged through a suitable outlet. The solid or other matter left within the strainer is removed by a belical series of fixed scrapers, which transfer it to a conveyor, by which it is discharged from the apparatus. The scrapers are mounted on a shaft carried by a movable headstock, by means of which they can be inserted in or withdrawn from the strainer.—R. A.

*Zinc and Copper Ores, Impts. in the Treatment of.* A. J. Boulton, London. From W. J. Koehler, Broken Hill, N.S.W. Eng. Pat. 20,615, Sept. 17, 1896.

THE zinc and copper being present in the form of oxide, the ore (or other material) is treated with ammonium sulphate

or "sulphamate" and heated to 300–500° C., whereby the two metals become sulphated, and ammonia is evolved. After leaching out the sulphates, the copper is precipitated by metallic zinc, and the zinc sulphate solution is passed through towers, where it meets the ammonia gas produced in the heating of a subsequent charge, and becomes converted into hydroxide, which may be dried, calcined, and sent into the market as zinc oxide. The ammonium sulphate obtained, is employed to treat another batch of ore. When iron is present it must be removed from solution before precipitating the zinc as hydroxide.—W. G. M.

*Nickel Ores, Impts. in the Treatment of, for Extraction of the Nickel and the Production of Iron Oxide Pigment.* T. Storer, Glasgow. Eng. Pat. 22,721, Oct. 13, 1896.

This process is said to be specially adapted to the treatment of ores containing silicates, as, for example, those from New Caledonia. The finely-divided ore, which should pass a sieve of 60 meshes per linear inch, is heated for about six hours under pressure to about 370° F. in admixture with ferric chloride solution, whereby nickel chloride solution is obtained, together with a fine red oxide of iron suitable for use as a pigment. The nickel may be recovered from the solution by any of the usual methods. The colour of the oxide of iron may be varied by altering either the temperature at which it is treated, or the strength of the solution. Usually a solution containing 25½ per cent. of solid ferric chloride is suitable for an ore with 5 to 8 per cent. of nickel, and 1,700 lb. of the dry salt would be used per ton of ore.—W. G. M.

*Metallic Alloys [Fe, Mn, Ni, &c.], Impts. in the Manufacture or Production of.* R. A. Hadfield, Sheffield. Eng. Pat. 21,705, Nov. 4, 1896.

The claims are for alloys of iron containing up to 1·5 per cent. of carbon, 15 to 25 per cent. of manganese and up to 25 per cent. of nickel, with or without chromium or tungsten, or both, up to 12 per cent.; and for similar alloys containing up to 1·5 per cent. of carbon, 7 to 25 per cent. of manganese and below 4 per cent. of nickel, with or without chromium or tungsten, or both, up to 12 per cent. Examples of the actual alloys are given, the composition varying according to the physical qualities required. The alloying metals are preferably melted separately, run into a suitable ladle, and the molten iron or steel poured into them.—A. W.

*Steel, Manufacture of; Impts. in.* W. P. Thompson, Liverpool. From La Société Civile d'Études du Syndicat de l'Acier Gérard, Paris. Eng. Pat. 25,161, Nov. 12, 1896.

In order to convert pig-iron directly into steel, the addition of an alkali metal (sodium) mixed with calcium chloride and lime is claimed. This mixture is to be charged into the crucible along with fragments of cast-iron, or it is to be introduced with the charge into the cupola, or wrapped in paper and plunged into the bath of metal in the foundry ladle.—W. G. M.

*Metals [Iron, Steel] or other Substances with a View to the Manufacture of Steel and for other Purposes, Impts. in the Pulverisation of.* W. P. Thompson, Liverpool. From La Société Civile d'Études du Syndicat de l'Acier Gérard, Paris. Eng. Pat. 25,462, Nov. 12, 1896.

The fluid pig-iron is run into a fireclay funnel-shaped vessel, provided at its lower extremity with an opening through which the metal runs into an outside casing supporting the vessel. It is here met with a forced current of air through a nozzle or other means, by which it is disintegrated into small globules which fall through another opening into a chamber in which it meets with an opposing current of hot air. By this means the globules are deprived of silicon, decarburised, &c., and the metal deposited into water in grains or as a dust ready for treatment with spiegel for conversion into steel. The disintegration of the stream of molten iron may also be brought about by pouring it on to a revolving clay disc, or by passing it between the terminals of an electric current of high density and low electro-motive force.—A. W.

*Crucibles and Furnaces, Lining of; Impts. in the.* P. E. Placet, Paris. Eng. Pat. 28,728 (under Internat. Convention), Dec. 15, 1896.

CHROMIUM compounds, such as the bichromate of magnesia, lime, alumina, or potash, are fused on the inner surface of the crucible, and the whole is then calcined; it thus becomes coated with an adherent refractory coating of chromium sesquioxide. The material may be applied initially by melting the bichromate of potash, if that be chosen, in the crucible, and then causing it to flow over the surface, or by heating the crucible and either rolling it in the salt or allowing it to remain sufficiently long in contact with a solution of the compound. It may also be applied in the form of a paste, mixed with tar, molasses, or oil; or in conjunction with ordinary refractory materials, carbon-lined crucibles or metallic surfaces may be coated. Mixed with such substances as magnesia, lime, &c., the material may be used as a cement in furnace building.

—W. G. M.

*Crucible Steel, Impts. in the Manufacture of.* S. Danner, Kladno, Bohemia. Eng. Pat. 29,846, Dec. 28, 1896.

INSTEAD of adding the raw materials to the crucible they are first subjected to a preliminary treatment in a converter or a Martin furnace, whereby the metal is freed from manganese, sulphur, and phosphorus, and the carbon reduced to the necessary quantity. The fluid mass is then poured into the crucible and the remainder of the refining process is carried on in the usual manner.—A. W.

*Sheet Metal, Method of Treating and Annealing.* W. E. Harris, Niles, Ohio, U.S.A. Eng. Pat. 13,672, June 3, 1897.

This is an improvement on the method specified in Eng. Pat. 9552 of 1896 (this Journal, 1896, 659). The sheets are hot-rolled, annealed, cold-rolled, and then stacked in an annealing box with a mixture of copper filings, soapstone, pulverised iron ore, and plumbago (mixed together, for example, in the proportions of 5, 10, 45, and 40 per cent. respectively) separating the different sheets. When thus finished the sheets have the appearance of Russia- or hammered plates without further mechanical treatment.—W. G. M.

*Slag [Tin], Impts. in the Treatment of, Resulting from the Smelting of Tin Ore.* C. C. E. Böhne, Kreis-Harburg. Eng. Pat. 14,325, June 12, 1897.

THE slags are decomposed in a granulated state by means of hot dilute sulphuric acid of 36° to 46° B. The residue then contains only 0·5 to 0·8 per cent. of tin and is used with two or three times its weight of quartz sand for making the hearths of tin-smelting furnaces, by which means this percentage of tin is also recovered. The tin in the sulphuric acid is recovered by electrolysis and the remaining iron sulphate solution evaporated for coppers.—A. W.

*Metallic Chlorides, such as those produced from Sulphide Ores; Impts. in the Treatment of.* E. T. Turner, Adelaide, South Australia. Eng. Pat. 17,834, July 29, 1897.

See under VII., page 914.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A.)—ELECTRO-CHEMISTRY.

*Cathode Rays, Modification of Salts by the Action of.* R. Abegg. Zeits. f. Elektrochem. 1897, 4, [4], 118—120.

THE surface-changes produced by the action of cathode rays upon the haloid salts of the alkalis are the more remarkable because these salts are amongst the most stable known. The discovery was made by Goldstein, who regarded the change as being of a physical nature. These changes were afterwards investigated by Elster and Geitel, and by Wiedemann and Schmidt, and it was suggested that

the change was a chemical one, which took place with formation of sub-haloid salts. The author has made experiments with the object of deciding between these two views.

Potassium chloride, sodium chloride, and potassium bromide are converted respectively into violet, brown, and blue modifications by the action of cathode rays *in vacuo*. There is no evolution of gas nor do the coloured salts when dissolved in water give any alkaline reaction (*i.e.*, if the salts originally taken are neutral and carefully purified). Their colour is not discharged by the action of chlorine, nor do they themselves decolorise permanganate solution. But by the heating action of very powerful cathode rays, they can always be transformed back into the white form; and this again, after cooling, can be changed into the coloured modification by a short exposure to the rays. These facts are not in accordance with the view that the coloured substances are sub-haloid salts; they tend to show that the change is a physical one. The change does not appear to affect the solubility of the salt.

Cathode rays exercise no reducing action upon cupric chloride, although the brown anhydrous cupric chloride is easily transformed into the white cupric chloride. Moist cupric chloride becomes blackened when exposed to sunshine. Cathode rays do not produce this effect; but, like sunlight, they colour calomel faint yellow. They turn silver chloride a deep violet-black. This colour is scarcely changed by the heating action of powerful cathode rays. The behaviour of silver bromide is different. It is coloured by cathode light (as by sunlight) deep grey. This colour is changed by heating to the original yellow (or perhaps nearer orange) and can be darkened again by light or cathode rays. As these changes take place in the dry salt *in vacuo*, they cannot well be due to any reduction or loss of chlorine or bromine.—D. E. J.

#### *Ionic Reactions and their Importance in Electro-Chemistry.* F. W. Küster. Zeits. f. Elektrochem. 4, 1897, 106—113.

A panegyric of Svante Arrhenius's theory of electrolytic dissociation, in the form of a lecture illustrated by experiments. This theory has transformed analytical chemistry from an art into a real science. At first sight electro-chemical theory appears to have only a slight connection with analytical chemistry. But in analysis we have to deal almost exclusively with aqueous solutions of salts (in an extended sense, including bases and acids) and it is just in these solutions, according to Arrhenius, that the salts are more or less split up into charged constituents—the ions. Different compounds (consisting of electrically neutral molecules) exhibit very different tendencies to split up into charged ions on solution in water. This tendency to split up into ions cannot be utilised as a source of electrical energy, for the positive charges cannot be separated in space from the negative charges simultaneously produced:—

(A point denotes a positive, a dash a negative charge; thus, a sodium-atom is represented by Na, a sodium-ion by Na<sup>+</sup>.)

An electrically neutral substance may withdraw from existing ions their charges, as when copper is precipitated from copper sulphate by metallic iron—

In this case a separation in space is possible, and the reaction can be used as a source of electrical energy. If in Fig. 1 both metals simply dip into a dilute solution of sodium sulphate, no appreciable (certainly no permanent) current passes along the wire. But if crystals of copper sulphate are introduced so that the copper is surrounded with copper sulphate solution, a current is set up. The sulphuric acid anions SO<sub>4</sub><sup>==</sup> play no direct part in maintaining the current; they are only necessary as determining the presence of a sufficiently large number of cations to perform this function.

When an ion is multivalent, a *part* of its charge may be removed by an electrically neutral substance; as when ferric ions are reduced by metallic iron to ferrous ions—

If in Fig. 2 the iron and platinum simply dip into a solution of common salt, no current is produced. But, if ferric chloride be introduced so as to surround the platinum

Fig. 1.

Fig. 2.

with ferric ions, a current is set up. The ferric ions transfer one-third of their charge to the iron plate, thus enabling it to form ferrous ions, and this goes on until all the ferric ions are themselves transformed into ferrous ions. Further examples of the formation and reaction of ions are given. One of these is a reversible process. Ferric chloride can set free iodine from potassium iodide; on the other hand, iodine is absorbed by ferrous salts with formation of ferric salts. Then the reaction—

can proceed in either sense until a certain state of equilibrium is attained.

The process of ionisation is itself reversible, as typified by the reaction—

In solutions such as are of practical importance, no electrolyte is completely split up into ions. The grade of dissociation depends upon the nature of the substance, the nature of the solvent, and the concentration of the solution. When a bottle containing a saturated solution of hydrochloric acid gas in toluene is opened, it fumes in the air just as the saturated aqueous solution of the gas does. But in the toluene solution the hydrochloric acid is not appreciably split up into ions. A galvanoscope indicates no current when two electrodes connected with a battery of E.M.F. 72 volts, are dipped into the solution. The ions are wanting, and so there is nothing to transfer the electricity. Now, the criterion of an acid is the presence of hydrogen-ions. As these ions are wanting in the toluene solution, it ought not, for example, to be able to evolve carbon dioxide from calcium carbonate; and as a matter of fact it does not. If water be added, carbon dioxide is given off, and the solution conducts well.

We must refer to the original, for explanations, based on the electrolytic dissociation theory, of other interesting reactions and experiments, such as the following. Water saturated with carbonic acid gas makes an acid solution of about  $\frac{1}{10}$  normal strength; but it only turns methyl orange slightly red. An acetic acid solution of  $\frac{1}{100}$  normal strength produces a much more distinct red colour. A mere trace of sodium bicarbonate restores the methyl orange in the carbonic acid solution to its original colour. The acetic acid solution behaves in a similar way towards an acetate; but here a larger quantity of the salt is requisite. Sulphuretted hydrogen precipitates black iron sulphide from a dilute aqueous solution of iron acetate. If the iron solution be acidified with acetic acid beforehand, it remains clear on passing in sulphuretted hydrogen; but if sodium acetate be also added, the iron sulphide is precipitated in spite of the presence of the same amount of free acetic acid. Strong acids behave quite differently. A single drop of hydrochloric acid turns a solution of methyl orange bright red; and, however, much sodium chloride be added, the colour is not altered. Sulphuric acid is considerably weaker than hydrochloric. A similar experiment with sodium sulphate shows that the addition of a very large quantity of the salt does noticeably diminish the action of the acid.

Some of the most interesting ionic reactions are those in which ions disappear as such and reappear in combination with other ions or molecules. There are certain reactions which are exhibited by all ordinary copper salts, and we conclude that these reactions are characteristic of the copper ion; for there is no other constituent which is common to all simple copper salts. But we know of solutions containing copper which do not exhibit these characteristic reactions, and we conclude that the copper is present in them, not as an independent ion, but as a constituent of a complex ion. Now we have every ground for assuming that solutions which are abnormal in their chemical behaviour will also prove to be abnormal in their electrical behaviour. An experiment is described proving that the assumption is quite correct in the case of Fehling's solution: for when this solution is electrolysed, the copper in it, instead of being transferred as a cation in the direction of the current, is transferred as a constituent of a complex anion in a direction opposite to that of the current.—D. E. J.

*Aqueous Solutions, Electrolytic Decomposition of.*  
W. Nernst. Ber. 30, 1547—1563.

THE electrolysis of water, at its discovery looked on as a direct decomposition, was later regarded as a secondary action, depending for its accomplishment on the presence of electrolysable substances in solution. More recently still, thanks to the work of Ostwald, Arrhenius, and van't Hoff, the idea of its being a primary decomposition has been reinstated. The modern theory of osmotic pressure and of electrolytic dissociation makes possible more definite views than formerly: the leading idea of this theory is to ascribe to the free ions all the properties of electrically neutral molecules, together with others arising from their electrical charges.

The electrolytic solution or precipitation of a metal is the resultant of opposing tendencies: on the one hand, the electrolytic "solution-pressure," or tendency of the metal to dissolve; on the other, the osmotic pressure of the dissolved ions and the electrostatic force with which the liquid, positively charged by the "initial solution" of metallic ions, opposes the introduction of more. When these opposing tendencies are equal, there is equilibrium; and if we now charge the metal positively or negatively, we have further solution or precipitation till equilibrium is restored.

The formula advanced by the author shows that the potential difference between metal and liquid is directly proportional to the "solution pressure," and inversely proportional to the osmotic pressure of the dissolved ion. The sign of this potential difference will be positive or negative as the electrode yields on solution cations or anions, and in the case of a voltaic cell with two metals and one liquid, the E.M.F. will be the difference between the potential differences at the metal-liquid contacts. Moderate changes in the concentration of either dissolved ion will affect the E.M.F. but slightly; but a great reduction in the concentration of one ion may alter the sign of E, or change the direction of the current. This has been experimentally shown by Ostwald in the case of the Daniell's cell, by adding potassium cyanide to the liquid in contact with the copper. The electrolytic cell differs from the battery cell in that solution or precipitation is going on at both electrodes—not solution at one and precipitation at the other; and hence the minimum E.M.F. which must be applied to overcome the potential differences of polarisation is the sum of the potential differences at the electrodes.

In the case of mixed electrolytes, Le Blanc has shown clearly, that as we raise the E.M.F. in the circuit, electrolysis of one of these takes place as soon as the minimum E.M.F. for that one is overstepped; and he has pointed out the applicability of graded E.M.F. for analytical separations. As a particular case of the principle, he has shown that in the case of many solutions, the water needs a lower minimum E.M.F. than the dissolved substance, so that a direct electrolysis of water takes place if too high E.M.F. be not used; in proof of this, he shows that the electrolysis of the most varied salt solutions in which the explosive mixture,  $H_2 + O$ , is evolved, needs the same E.M.F., 1.68 volt. If this minimum E.M.F. be greatly exceeded the salt

also is decomposed, and then the accumulation of alkali at the cathode, and of acid at the anode, rapidly changes the concentration, and the progress of the decomposition is complicated by diffusion and convection currents. For practical purposes, electrolysis of neutral solutions is to be avoided.

While the requisite E.M.F. for the electrolysis of hydrochloric acid (1.3 volt) is also that yielded by a chlorine and hydrogen gas battery, the E.M.F. of a hydrogen and oxygen gas battery (1.08 volt) is far below that needed (1.68 volt) for the electrolysis of water or of one of the solutions just referred to. Le Blanc has attempted to explain this on the assumption that the liberated oxygen while in solution is in a state of supersaturation; but experiments of Glaser and the author, in which sulphuric acid and potassium hydroxide solutions were electrolysed by gradually increased E.M.F.'s have shown that an E.M.F. of 1.08 will decompose water if a sufficient surface of anode is given, and that different ionic decomposition-correspond with different E.M.F.'s, the lower E.M.F. (in the case of water) working upon ionic oxygen, which exists but in low concentration, the higher with ionic hydroxyl, which is present in much higher concentration.

The following table shows the necessary "decomposition-electromotive force" for each ion in normal concentration, hydrogen being taken as zero:—

Cations.		Anions.	
Az.....	- 0.78	I.....	0.52
Cu.....	- 0.34	Br.....	0.96
H.....	- 0.00	O.....	1.36
Ph.....	- 0.17	Cl.....	1.31
Cd.....	- 0.38	OH.....	1.68
Zn.....	+ 0.74	SO <sub>4</sub> .....	1.90
		H <sub>2</sub> SO <sub>4</sub> .....	2.69

From this table many practical conclusions can be drawn:—Zinc bromide, for example, needs for decomposition  $0.74 + 0.94 = 1.68$  volt. The separation of copper from silver, or of iodine from bromine, is seen to be easily practicable, electrolytically, as the figures for each pair differ so widely; and so forth.

It is to be noted that to accomplish electrolysis at any considerable rate, with E.M.F.'s just above minimum, we must have the ions in sufficient concentration; for this reason, while it is true that the direct electrolysis of the water of a solution may be possible, it is usually a secondary action, the higher concentration of the salt ions causing electrolysis of the salt rather than of the water to take place chiefly, in spite of the lower E.M.F. at which the latter can occur. The same thing explains the fact that chlorine displaces oxygen, for example, so much less readily and rapidly than bromine, though the minimum figures for oxygen and for bromine lie so near together.

The same fundamental principles throw light on the decomposition of water by metals with evolution of hydrogen. From the formula for the E.M.F. of a cell, we see that the conditions favourable to the displacement of hydrogen are, high osmotic pressure of the hydrogen ions, low osmotic pressure and high solution-pressure on the part of the metal. Potassium, for example, decomposes water on account of its enormous solution-pressure. Zinc decomposes water in acid solutions because the concentration of the hydrogen ions is considerable; and in alkaline solutions, though the hydrogen concentration is slight, because the zinc concentration, through the formation of zincates, is slighter still; but it will not decompose water in a neutral solution of zinc sulphate, where the zinc concentration is high and the hydrogen concentration low. In the electrolysis of a solution of a salt the same principles still hold: metal or hydrogen will be precipitated according to the solution-pressure of the metal and the relative magnitudes of ionic concentration of metal and of hydrogen. The practical bearings of this are obvious.

Attention is drawn to the formation at the electrodes, of compounds, by the coalescence of two similar ions deprived of their electric charges—not only molecules of elements,

but such bodies as  $H_2S_2O_8$  and  $K_2C_2O_6$ . Both this, and the variation of osmotic pressure at the electrodes by altering the E.M.F. applied, promise, especially in the domain of organic chemistry, to be fruitful in the preparation of new compounds electrolytically.—J. T. D.

### (B.)—ELECTRO-METALLURGY.

*Chromium, Electro-Metallurgical Process for obtaining.* Aschermann. D.R.P. No. 93,744, June 30, 1896. *Zeits. für Elektrochem.* 4, [8], 214.

A gas-tight electric smelting furnace of cast steel, with a very dense movable carbon electrode, is used. A tightly fitting crucible of graphite is placed within the outer case of steel, and is charged with 10 parts of chromium sesquioxide and 23 parts of antimony sulphide, or with 10 parts of chromium sesquioxide, 10 parts of sulphur, and 23 parts of pure antimony. The former mixture is to be preferred, since a better yield is obtained when it is used, and the crucible suffers less. The apparatus is closed, and a current of from 20—25 amperes is passed through it. This suffices to melt the mixture, and causes an exothermic chemical reaction to occur. When the reaction is completed, a deposit, chiefly amorphous, of antimony trioxide, antimony sulphide, and chromium sesquioxide will be found upon the upper part of the crucible and furnace, whilst in the crucible itself there will be found a molten alloy of chromium and antimony, distinctly crystalline in structure. By repeated melting in this furnace it is possible to remove every trace of antimony from the chromium, but this method of purification is inconvenient and costly. A simpler and less expensive plan is to break the alloy when cold into small pieces, and to drive out the antimony from these by volatilisation at a white heat over an ordinary coke or coal fire. Molten chromium takes up, or dissolves, a considerable amount of carbon. On cooling, this carbon separates out as graphite. Chromium is volatilised at temperatures over  $2,000^\circ C$ .

## XII.—FATS, OILS, AND SOAP.

*Degras, Artificial, Manufacture of.* C. Baron. *Rev. Chim. Ind.* 1897, 8, 225.

A VESSEL holding about 6,000 kilos., built of tinned steel in the shape of a cylinder with an inverted cone at the base, provided with an air agitator, a dry steam coil, and several draw-off cocks at different positions, is charged with 1,000 kilos. of neutral wool fat (extracted with petroleum spirit) and 5,000 kilos. of cod-liver or whale oil. The liquid is heated by means of the steam coil, agitated for three hours, then allowed to rest and cool for the same period, and the water is withdrawn. The oil is again heated to  $10^\circ$ , 150 kilos. of hydrogen peroxide and 450 kilos. of water added, and the whole agitated for five hours at a pressure of two atmospheres. The resulting product forms an excellent mœillon, having a yellow colour, and being easily emulsified and absorbed by the skins. It is very important that the wool grease shall be free from (sulphuric) acid, lest this should dissolve traces of iron, and so give rise to the darkening of the leather owing to the formation of iron inks. (See also p. 937.)—F. H. L.

## XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

### (1.)—PIGMENTS, PAINTS.

*Red Lead, The Dissociation of.* H. Le Chatelier. *Bull. Soc. Chim.* 1897, 17, 791—792.

RED lead at the upper closed end of a vertical tube, the lower end of which was connected with a mercury manometer, was heated to temperatures which were determined by the author's thermopile, and its dissociation pressures found to be, at  $445^\circ C$ , 5;  $500^\circ$ , 60;  $555^\circ$ , 183; and  $636^\circ$ , 763 mm. Thus in air (oxygen at 150 mm. pressure), red lead cannot be formed above  $550^\circ C$ , but is produced most rapidly about  $500^\circ C$ .

Red lead was found to undergo allotropic change at  $580^\circ$ , the oxide melting at  $830^\circ$ . The author considers that when melted litharge is exposed to air, red lead is formed, and is dissolved as formed in the litharge, the dissociation pressure being, in effect, lowered through dilution of that red lead in the excess of litharge. On subsequent cooling, the red lead tends to separate out in the solid form and then suddenly finding itself under a pressure of 30 atmospheres, it is decomposed in the act of solidification and thus breaks up the mass.—J. T. D.

*"Mosaic Gold" (Crystalline Stannic Sulphide), Preparation of.* J. Lagutt. *Zeits. angew. Chem.* 1897, 537.

ACCORDING to most of the text-books, the reason for including ammonium chloride in many of the recipes used for preparing bisulphide of tin, is to prevent the temperature of the mass rising too high and thus causing the formation of the monosulphide. This explanation is evidently erroneous, and the rôle of the ammonium salt is rather a chemical one; for the author finds that in order to obtain a satisfactory product it is necessary to have the tin present in a volatile form, or to add to the other ingredients some substance which shall cause the metal to assume this shape, such as mercuric chloride, bromine, hydrochloric acid, or ammonium chloride.

The following formulae give good results:—For a pale yellow mosaic gold, 50 grms. of crystallised stannous chloride and 25 grms. of flowers of sulphur; for a reddish shade, 50 grms. of 50 per cent. tin amalgam, 25 of crystallised stannous chloride, 35 of ammonium chloride, and 35 of sulphur. The materials are finely powdered and are ignited gradually in a glass retort covered with asbestos in the flame of a large blowpipe, which should be moved about periodically in order that the charge may be equally heated all through. During the operation the colour of the mass should be dark brown; if it become black owing to the formation of stannous sulphide, the flame should be lowered. The yield is about 57 per cent. of the theoretical, calculated on the amount of tin employed.—F. H. L.

*Driers and their Effect on Linseed Oil.* M. Weger. *Zeits. angew. Chem.* 1897, 401, 542, and 560.

THE first portion of this article consists chiefly of a criticism of Amsel's paper (this Journal, 1897, 685).

Inasmuch as a substance can only act on linseed oil as a drier if it be in a state of true solution, the chief advantages that the resins and linoleates of lead and manganese possess over the metallic oxides formerly employed, lie in their ready solubility at lower temperatures, a phenomenon which evidently demands that they shall be compounds and not simply mixtures. At the present time there is no means of deciding whether the resin and linseed acids found on analysing these driers are present as metallic salts, or whether they merely exist in the free state or as esters, side by side with uncombined inorganic bases; and the suggestion recently made by Amsel (*loc. cit.*) that the point may be settled by a simple determination of the total mineral matter is obviously quite valueless. Until, therefore, some new analytical process has been worked out which will throw more direct light on the constitution of these bodies, it is necessary to estimate the soluble inorganic matter (*i.e.*, the lead or manganese soluble in such liquids as oil of turpentine, &c., because combined with resin or linseed

acids) and, by means of the combining proportions already given (this Journal, 1896, 728), to calculate this either into resinate or linoleate, according to the average-acid or saponification number of the whole sample. As an instance, a fused manganese-lead resinate, contained 9.90 per cent. of soluble Pb, and 1.43 per cent. of soluble Mn, other metals being absent. The material was therefore composed of  $(9.9 \times \frac{100}{24}) = 41$  per cent. of lead resinate and  $(1.43 \times \frac{100}{5.3}) = 27$  per cent. of the corresponding manganese salt, or 68 per cent. of active ingredients in all; and the amount of free resin (colophony) must have been 30 or 35 per cent.

Amself's plan of estimating the moisture in the soluble driers is not of much use, for the resinates of lead and manganese obtained by precipitation, generally contain about 6 per cent. of water in their air-dried condition; and it never rises to 20 or 33 per cent. Linoleates prepared in a similar manner are very difficult to dry, often retaining water in distinct drops, whence it follows that they are of little practical value, and they are, indeed, seldom if ever met with commercially. Determination of the moisture, in fact, only serves to distinguish between fused and precipitated resinates, which cannot always be done with certainty by means of the microscope.

The author has investigated the action of a number of other compounds of manganese on linseed oil, including the monoxide, sesquioxide, and dioxide, each in the hydrated state, ordinary black oxide, chloride, sulphate, nitrate, chromate, borate, carbonate, oxalate, succinate, citrate, tartrate, benzoate, formate, and acetate. The salts of organic acids just mentioned, with the exception of the acetate, appear unsuited for the manufacture of varnishes, as they offer no advantages commensurate with their high prices. The acetate yields a well-drying varnish on heating with the oil for two hours at 120°; the nitrate is decomposed between 120° and 140°, and the resulting oxide dissolves completely at 150° to 170°; the black oxide involves a temperature of 250°. The hydrated oxides all dissolve between 170° and 220°, but before being taken into use they should be examined as to the amount of metal and available oxygen they contain, for they vary very much in purity, as is shown in the annexed table:—

#### COMPOSITION OF COMMERCIAL MANGANESE HYDRATES.

	Mn.	Available O.
	Per Cent.	Per Cent.
MnO <sub>2</sub> .H <sub>2</sub> O .....	38.11—53.67	10.14—10.87
Mn <sub>2</sub> O <sub>3</sub> .H <sub>2</sub> O .....	44.03—52.63	5.55—10.05
MnO.H <sub>2</sub> O .....	51.70	5.32

The proportion of manganese in the borate of commerce ranges from 5 to 22, being usually about 15, and the substance apparently consists of 2MnO.3B<sub>2</sub>O<sub>3</sub>.3H<sub>2</sub>O. Whilst in the case of an addition of 2½ per cent. of manganese sesquihydrate agitated and intimately mixed in the cold by means of a current of air, with linseed oil, from 20 to 30 hours were required to show drying effect, and with 10 per cent. of manganese sulphate rubbed up for four hours (cold) with the oil, some 30 hours were required, yet in the case of 1 per cent. of manganese borate (containing 20 per cent. Mn) after rubbing up for one hour (cold), the time for drying was only 7 to 15 hours. Thus, whilst an undissolved drier is without action, a long-continued and extremely intimate mixture of drier with oil, can, even in the case of other than completely soluble preparations, to a certain extent replace any raising of the temperature. The ready solubility of borate of manganese presumably depends on the acidity of the oil, for the acid number of ordinary samples is about 2.5, and this represents a capacity for dissolving 0.12 per cent. of Mn (as monoxide), which is amply sufficient to yield a quick-drying varnish.

Turning to the influence of driers in general on linseed oil, it should be noted that an exact determination of the speed at which varnish dries is a problem of considerable difficulty, and two different observers working on one

sample under apparently similar atmospheric and other conditions may find discrepancies amounting to 25 per cent. in the time required. The drying is affected by alterations in the temperature, moisture, and rate of motion of the air, and, notably, by the degree of light to which the glass plates carrying the films of oil are exposed. Variations of one-half to one hour may often be experienced between two trials of the same specimen of varnish at different times in one day, or of 50 per cent. between tests made in the day and at night; while a sample drying in two hours in the direct rays of the sun may take five or even eight hours if it is only placed in diffused daylight. For these and similar reasons it is impossible to express the value of any particular drier, or the speed of any definite varnish, in absolute terms; and it is indispensable, therefore, that all the materials which have to be studied shall be tested simultaneously, or that they shall be examined in juxtaposition to a standard varnish the behaviour of which is thoroughly understood.

To prepare a suitable standard, manganese resinate might be dissolved by heating to 150° in about four times its weight of a pure linseed oil kept specially for the purpose, the solution filtered, and diluted till it contains a convenient amount of metallic manganese, e.g., 0.1 per cent. This may be rendered still weaker if necessary; but it is important to observe, for reasons indicated hereafter, that the varnish must be freshly made up each time it is employed.

It is usually believed in the trade that there is a well-defined limit to the proportion in which lead or manganese may be advantageously introduced into linseed oil, because above a certain point the drying power of the varnish is thereby diminished. Evidence of this retrogression the author cannot discover; and while the rapidity of drying at first increases with every addition of drier, provided always that the metal is actually dissolved, excess of the latter simply produces no effect on the speed. As the result of a large number of experiments, for full details of which the original communication must be consulted, Weger finds that for all practical purposes the maximum in the case of manganese resinate is 0.25 per cent. of metal, or, if a manganese-lead resinate be employed, 0.5 per cent. of Pb and 0.1 per cent. of Mn. Corresponding tests with the linoleates do not yield equally clear indications, but it is certainly useless to add more than 0.2 per cent. of Mn in the shape of its linoleate, and probably 0.1 per cent. would be preferable. Such quantities as these, moreover, must only be introduced into the oil when speed is the primary consideration; for it seems to be well recognised that the durability of the film is seriously affected by increasing the amount of foreign matter present, or, in other words, that linseed oil by itself yields the most permanent varnish of all.

Varnishes containing manganese linoleate, and occasionally those with the corresponding borate, do not attain their full drying power until they are eight days old; while such as are made with mixtures of lead and manganese, or with litharge and black oxide of manganese in the old-fashioned way, are apt to diminish in speed on keeping, more particularly during the first few weeks. This peculiarity does not of itself negative the idea that a varnish is improved by age, for rapidity of drying is manifestly only one of a number of properties sought after in these products.

Attempts were made to discover if there is any practical difference between the activity of a definite amount of lead or manganese in the form of the linoleate and the same quantity of metal as resinate; some of the results seem to be slightly in favour of the fatty salt, but the evidence is not yet conclusive. Other experiments show that it is immaterial whether the drier (Pb + Mn) is dissolved in the oil at ordinary atmospheric temperatures or by heating them (drier and oil) together at 150° to 260° C.—F. H. L.

#### PATENTS.

*Anti-fouling Composition or Paint for Ships, A New or Improved.* F. Scott, Swansea. Eng. Pat. 25,549, Nov. 13, 1896.

ONE cwt. of tallow, two of sulphur, two of resin (colophony), 12 lb. of verdigris, and 1 gall. of turpentine are mixed together, and the composition is used either hot or cold as may be more convenient.—F. H. L.

*Coating Ships' Bottoms to Prevent Fouling and Corrosion, Impts. in; applicable also to the Coating of Tanks and the like to Prevent Corrosion.* A. C. Furse, London. Eng. Pat. 25,675, Nov. 14, 1896.

This consists of finely-divided metallic aluminium suspended in a vehicle composed of liquid celluloid, or shellac dissolved in a suitable solvent.—F. H. L.

*Manufacture of [Red] Lead Pigments, Impts. in or connected with the.* J. Fairlie, Glasgow. Eng. Pat. 26,322, Nov. 21, 1896.

The object of this patent is to treat red lead in such a way that it shall not settle or deposit from linseed oil after it has been ground therein; so that it may be put on the market in the form of a paste, as is done with white lead. To the dry pigment are added sodium chloride and sulphate, potassium iodide and bromide, magnesium chloride and sulphate, and calcium chloride in amounts not exceeding 1 per cent. altogether; and the whole is mixed, "levigated with water," and dried.—F. H. L.

*Glaze: Paint specially for Painting Ships' Bottoms, Process for the Production of.* L. de Bruycker, Hamburg. Eng. Pat. 7128, March 18, 1897.

250 grms. of aloes are dissolved in 100 grms. of methylated spirit, 4,000 grms. of "thick turpentine," and 750 grms. of linseed oil added, and the whole boiled till no scum is formed. 950 grms. of linseed oil are boiled separately with 25 grms. of lead acetate, 10 grms. of white lead, and 15 grms. of litharge until the mass becomes dark brown, and it is then combined with the first mixture. Finally, the composition is thinned with 750 grms. of petroleum spirit and 250 grms. of oil of turpentine, the desired pigment is introduced, and the paint is ground in the usual manner.—F. H. L.

*Wood-Stain, New or Improved.* H. E. Junghans, Sebramberg, Württemberg. Eng. Pat. 7540, March 23, 1897.

The application of a dye dissolved in water or alcohol to wood has the disadvantage of causing the grain to "rise"; and when the surface is sandpapered again to make it smooth, the stain is apt to be removed irregularly. To obviate this trouble the inventor uses as a solvent for his colouring matter, benzene, turpentine, or the anthracene oil known in commerce under the name of carbolinum.—F. H. L.

*Anti-Fouling and Anti-Corrosive Paint, An Improved.* R. Hingston and J. C. Rankin, Sydney, N.S.W. Eng. Pat. 8811, April 6, 1897.

The following substances are ground together:—Red ochre, 38 lb.; yellow ochre, 29; purple oxide of "zinc" ("purple brown"), 3; "double-boiled" linseed oil, 19, and crebène, 15 lb.; also turpentine and methylated spirit, of each 8 oz. Finally, 5 lb. of mercuric chloride, 1 lb. of copper sulphate, and 1 lb. of white arsenic are added in fine powder, and the whole is well stirred up.—F. H. L.

*Insulating and Weather-, Acid-, and Fire-Resistant Material applicable as a Paint, or for other Purposes; An Improved.* J. Stocker and H. Zander, Rathenow, Germany. Eng. Pat. 16,490, July 12, 1897.

Three parts of caustic alkali are dissolved in 20 of soda or potash water-glass, 10 of fireclay are added, and, after standing two hours, 2 of clay powder, 6 of "asbestos powder" or "wool," and the desired colouring matter are introduced, and the whole mixed together. For impregnating canvas, sail-cloth, &c., this composition is treated at 100° C. with 10 parts of earth-nut oil and 5 of hydrochloric acid; for use as a waterproof paint, it is ground with 5 parts of earth-nut oil alone; and for the preparation of an insulating mass or a substitute for hard rubber, it is mixed with oil as in the last case, but with the addition of 2 parts of isinglass. The plates, &c. made from it are moulded at 110° to 120° C. under hydraulic pressure.—F. H. L.

*Composition specially adapted for Printers' Inking Rollers and the Like, Improved Compound or* J. W. White, London. Eng. Pat. 17,123, July 20, 1897.

This composition consists of gelatin, 1 lb.; golden syrup, 3 lb.; oxide of zinc, 1 oz.; glycerin, 1 gill; and water, *quant. suff.* The addition of the zinc oxide to the ordinary formula causes the rollers to have an opaque white surface; and it is, therefore, easy to see whether they are properly clean, before a pale-coloured ink is applied to them.—F. H. L.

*White Lead, Improved Apparatus for Use in the Manufacture of.* A. H. Eyles, Pelhamville, New York, U.S.A. Eng. Pat. 19,030, Aug. 17, 1897.

This specification describes an improved carbonising machine for use in the manufacture of white lead by the precipitation process. A cylindrical vessel mounted on hollow, horizontal axes is provided on its inner surface with a number of bars of perforated angle-iron, bolted to the walls in a direction parallel to its axis, but divided into several short lengths, and so fixed that each length "breaks joint" or is "staggered" as regards its neighbours. These pallets or beaters act as agitators, and as the barrel revolves, its contents are thoroughly and uniformly exposed to the action of the gases present in the vessel. The inlet pipe is branched so that carbonic acid and oxygen can be introduced together; and both inlet and outlet are fitted inside the vessel with baffle plates.—F. H. L.

### (B).—RESINS, VARNISHES.

*Varnish, Unboiled Linseed.* H. Amsel. Chem. Zeit. 1897, 21, 690.

An unboiled linseed varnish may be defined as a product which has been made by dissolving a metallic resinate or "oleate" in linseed oil at a temperature not exceeding 180° C., in contradistinction to one prepared by the original process of heating the oil with metallic oxides at or above 250°. The author has examined a large number of these materials—some of his own manufacture, others commercial specimens—with regard to their speed of drying and the character of the films they yield; and he now (this Journal, 1895, 814) concludes that they are at least equal in value to the old high-temperature varnishes. Whenever the samples do not dry satisfactorily on glass in 24 hours, he employs Kissling's process of determining the weight of oxygen they absorb in a definite period of time, either in the sun or in diffused light; but as both tests lead to the same result, and the latter takes much longer to carry out, he prefers the former method. "Ozonised" oils in general, dry more slowly than boiled varnishes, but they yield remarkably smooth and brilliant films which should render them specially suitable for many purposes.

To distinguish between resin oil and mineral oil in linseed oil varnish, the sample may be rubbed down with zinc oxide; if the mass thickens to a cheese-like consistency in 24 hours, the former is present, whereas mineral oil has no such effect. Ten or more per cent. of cotton-seed oil in a varnish can also be detected in a precisely similar manner.—F. H. L.

*Balsams, Resins, and Gum Resins, Rational Examination of.* K. Dieterich. Chem. Rev. Fett u. Harz Ind. 4, [17], 233.

See under XXIII., page 940.

### PATENT.

*Varnishes, Paints, and the like; Impts. in or connected with the Manufacture of.* I. Goldblum, Lublin, Russian Poland. Eng. Pat. 18,519, Aug. 10, 1897.

As a partial or total substitute for linseed oil varnish, 50 parts of common resin (colophony) are dissolved in 100 parts of benzene or some similar solvent, 12 to 15 parts of crystallised sodium carbonate are added, and the whole finally filtered or decanted. "Washing" paints may be made by grinding pigments to a stiff paste with boiled oil, allowing the mixtures to dry, and then grinding the resulting powder with the above-mentioned vehicle.—F. H. L.

## (C).—INDIA-RUBBER, &amp;c.

*Gutta Percha*, Composition of. J. A. Montpellier. Rev. Chim. Ind. 1897, 8, 237. (See also this Journal, 1897, 815.)

**GUTTA** percha consists of a mixture of three resins: *gutta*,  $C_{20}H_{32}$ ; *fluavile*,  $C_{20}H_{32}O$ ; and *albane*,  $C_{20}H_{32}O_2$ . The first is the body to which the material owes its industrial value, and it forms from 40 to 85 per cent. of the whole. At 10° to 20° C. it is white, soft, but not elastic; at 45° it becomes yellow and pasty; between 100° and 110° it softens; and at 130° it melts, boils, and is decomposed into an oil and a gaseous hydrocarbon. Gutta is soluble in chloroform, toluene, and carbon bisulphide; insoluble in dry alcohol, and also ether—at least, after treatment with the former. It oxidises in the air, and is decomposed by hot nitric acid, formic and hydrocyanic acids being formed. Hydrochloric acid converts it into a dark brown substance. Fluavile is a yellow, brittle, amorphous resin, softening about 50°, and melting at 100°—110°. It is heavier than water. It dissolves cold in dry alcohol and ether, benzene, toluene, oil of turpentine, carbon bisulphide, and chloroform. Strong alkalis, weak acids, and concentrated HCl are without action. Albane is a white resin, crystallising from hot alcohol, softening at 160°, and melting, without decomposition, at 175°—180°. Its solubility resembles that of fluavile, except that alcohol only takes up 5.1 per cent. in the cold and 54 per cent. at the boiling point. In presence of acids and alkalis it also behaves like fluavile. Heated to 130° it loses one molecule of water.

Attempts to value the gutta percha of commerce should be based on the determination of the proportion of pure gutta, moisture, and other impurities.—F. H. L.

## XIV.—TANNING, LEATHER, GLUE, SIZE.

*Canaiigre*, Cultivation of. W. Eitner. Der Gerber, 23, [554], 232.

E. ANDREIS, of Turin, in a pamphlet entitled "Il Canaiigre," gives a very full description of its properties, and also advocates the cultivation of the root in Italy.

This has been already undertaken in Arizona and New Mexico by several companies. The commercial results are yet unknown, but there is little doubt that in America, canaiigre extract will to a great extent replace gambier. The author has made several attempts to grow canaiigre in Vienna and in Bosnia, latitude 43°, but without success; the cultivation from seeds is rarely successful. A later trial in Smyrna has been successful on a small scale, but as the first year's roots never contain much tannin, it will be some time before the experiment can be pronounced a success. It is questionable from these trials whether canaiigre will grow in a latitude much north of its original habitat. The author, however, is of opinion that it will be successfully grown in the Levant.—J. T. W.

*Palmetto Extract*. W. Eitner. Der Gerber, 23, [550], 184.

This is the extract of the root of a kind of Palmetto palm (*Corypha Palmetto*) which is grown in Georgia and Florida. An analysis of the extract (30° B.) gave—

	Per Cent.
Tanning matters .....	18.01
Sol. non-tannin .....	20.06
Water .....	19.96
Insoluble .....	2.71
Ash .....	9.26

The amount of tannin is not high for an extract, while the non-tannin is considerable and easily fermentable, so that the liquors soon become sour.

The ash consists principally of potassium chloride, which appears to be due to the roots having been treated with potash, and afterwards neutralised with HCl.

Used alone, palmetto extract produces a hard brittle leather, of a dirty reddish-grey colour; with other materials, however, it makes a good sole leather. It is best used in the final processes, and not in the colouring pits.—J. T. W.

*Fermentation Phenomena in Tan Liquors*. F. Andreaseh. Imp. Research Laboratory, Vienna. Der Gerber, 23, [511], 69; 23, [543], 95.

A supply of nitrogenous substance is absolutely necessary for the proper production of acid. The author shows that this is furnished by the hides themselves. Practical fermentations were conducted in tan liquors from different sources, the nitrogen in the fermented liquors being estimated, and also its mode of combination.

Old tan liquors contain albumoses and peptones along with amino acids and alkaline products of putrefaction. Corin, hide fibroin, and semiglobin are also present; the latter, or a very similar body, occurring in large quantities in lined hide. Bated skins introduce different decomposition products of albuminoids by bacteria. The nature of the nitrogenous compounds was examined (after freeing the liquid from tannin by gently heating with calcined magnesia) by means of the following tests:—

1. The xantho protein reaction.
2. Millon's reagent.
3. Precipitation with  $NaClO_3$  and HCl.
4. The Biuret reaction.

The following table (A) gives some nitrogen analyses of tan liquors in the tannery:—

TABLE A.

Number of Colouring Pits.	Per Cent. N in 100 parts Dry Extract.	Grms. N in 100 c.c. Liquor.	
I. (weakest) ....	0.5621	0.0036	From a series of 9 sole-leather colouring pits. Pine bark liquors.
II. ....	0.4201	0.0138

VII. ....	0.2508	0.0109	
IX. ....	0.2113	0.0082	
I. (weakest) ....	0.3249	0.0051	Very old calf colouring liquor. Oak and pine barks.
II. ....	0.3612	0.0064	
VI. ....	0.5811	0.0068	
IX. ....	0.3481	0.0065	
X. ....	0.3202	0.0053	
VI. ....	0.2159	0.0048	
I. (weakest) ....	0.3292	0.0045	From a series of 10 sole-leather colouring pits. Pine liquors.
II. ....	0.2429	0.0044	
V. ....	0.2500	0.0045	
VII. ....	0.1917	0.0046	
IX. ....	0.1544	0.0035	
X. ....	0.1467	0.0025	

It will be noticed (Table B, this Journal, 1897, 748) that the acidity of the liquors increases with the amount of nitrogen, though not always proportionately; this is owing to the irregular absorption of acids by the hides, besides which the nitrogenous bodies, even in the same series of liquors, are not always of similar nature. Comparing the N in the used liquors (Table A, above) with that of the original materials (This Journal, 1897, 748) an increase of N is shown, although there is less tannin, and this increase can only come from the hides.

Fermentations in presence of hide showed conclusively that the increased acidity depended solely on the nitrogenous substances present, and further, that not only is the soluble nitrogen utilised, but that the fresh or slightly tanned hides directly contribute towards the fermentation in a similar way to that in which coagulated albumin or precipitated casein in cheese, influence the formation of lactic acid.

The hide used in the experiments was sterilised in the following way:—Pieces of unlined hide were shaken for several hours in a fresh sterilised lime liquor. The lime was then removed partly by washing in sterilised water and partly by passing  $CO_2$  through the vessel. The hide then remained for three weeks in water saturated with  $CO_2$  in the incubator at 25°, those pieces which gave no development of bacteria on a gelatin plate being used.

The following tables give the results of these experiments. The first table (B) gives fermentations in a solution of glucose 3 grms. per 100 c.c., with the necessary mineral salts, but no other nitrogenous material than the sterilised hide.

TABLE B.

Grm. Lactic Acid in 100 c.c. after  
3 Weeks at 36° C. Inoculated with Lactic  
Acid Bacterium from Tan Liquors.

	Original Solution.	Original Solution.		
		4·2 grms. Hide per 100 c.c.	8·5 grms. Hide per 100 c.c.	17·0 grms. Hide per 100 c.c.
Total lactic acid .....	0·0453	0·1470	0·2500	0·5009
Lactic acid due to hide..	..	0·1017	0·2117	0·4556

Table C gives the results of fermentations of the most generally used materials. Pine-bark and myrabolan liquors were also employed after removal of the tannin, in order to ascertain its influence on the fermentation.

Limed cow-hide and calf skin, sweated cow-hide and bated calf skin were used. The figures refer to the weight of dry hide.

Except where there is a great excess of hide in comparison to the fermentable non-tannins, the author shows that the following law holds good:—The formation of lactic acid depends on the previous treatment of the hide, and with the same hides, is proportional to the weight of hide substance present.

TABLE C.

*Fermentation with Lactic Acid Bacterium of Tan Liquors for 20 Days at 30° C.*

#### PATENTS.

*Tanning Hides and the like, Impts. in the Method of and  
Means for.* J. Forster, Warrington. Eng. Pat. 22,103,  
Oct. 6, 1896.

The hides are suspended in the pits on frames mounted on wheels. The rails on which the wheels run consist of a series of inclined planes. A reciprocal motion being given to the frame, the hides are thereby lifted and lowered in addition to the horizontal motion. The motion is continued during the whole of the process.—J. T. W.

*Leather, Artificial, or Leather Substitute, Improved Manu-  
facture of.* A. J. Bonlt, 111, Hatton Garden. From  
G. Brigalant, Barentin, France. Eng. Pat. 15,404,  
June 28, 1897.

LEATHER waste is shredded and made into a paste, textile substances such as hemp, flax, jute, &c. being added along with glue. The "fibrolenn" thus prepared is made into sheets, compressed, dried, and rolled.

It may be used for any purposes for which leather or leather substitutes are employed.—J. T. W.

*Leather or Skins, Washable, Impts. in or relating to the  
Manufacture of.* J. L. Garein. Grenoble. Eng. Pat.  
16,477, July 12, 1897.

SKINS are first tawed or partially tawed, and then tanned either by the usual process or by means of chrome.

Leather prepared in this way does not lose its suppleness and elasticity by the action of water; in short, it is claimed that a washable leather is formed.—J. T. W.

*Manure, Manufacture of, from Waste Leather and Phos-  
phate of Lime.* W. E. Rowlands, Seacombe, Chester.  
Eng. Pat. 17,926, July 30, 1897.

See under XV., page 927.

*Leather Substitute, Manufacture of and Apparatus for  
Use therein.* Leon de Banville, J. F. Ronleau, and  
L. V. Rancelant, Paris. Eng. Pat. 24,885, Aug. 6, 1897.

THE substitute consists of an intimate mixture of leather waste and rubber solution. The waste used is the fluff from the skins used in glove manufacture.

The mixture or paste is spread between two parallel webs by means of a special machine of which drawings are given. It is dried on the webs and afterwards embossed in imitation of Cordovan, &c.—J. T. W.

*Tanning, Impts. in Apparatus for.* E. Du Bois, Ralston,  
Penn., U.S.A. Eng. Pat. 19,874, Aug. 28, 1897.

THE tan pits are fitted with frames the cross-bars of which are provided with a series of hooks above and below the centre of vibration, the upper series being in different vertical planes from the lower series on each bar; the frame is given a vertical motion within the vat, and the cross-bars of the frame an oscillatory motion by means of the mechanism illustrated, so that adjacent sides of leather are made to move in opposite directions. These motions thoroughly agitate the tan liquor and cause it to circulate freely between the leather "sides."—J. T. W.

#### XV.—MANURES, Etc.

*Denitrification, Recent Experiments on.* W. Somerville.  
Jour. Royal Agric. Soc., Eng., 1897, [3], 8, 477—490.

THE results of experiments made by Macreker and by Wagner, in which different plants grown in pots were variously manured, showed that in presence of sufficient

phosphoric acid and potash, less produce was obtained when dung was supplied than with nitrate of soda, and that dung in conjunction with nitrate of soda gave rise to a considerable decrease in the amount of produce as compared with nitrate of soda alone. It was further shown that horse dung may induce loss of nitrogen in bare soil. Garden soil (3.4 kilos.) containing potassium phosphate and nitrate of soda (N = 0.5 grm.) lost more than half the nitric nitrogen in six weeks after the addition of 600 grms. of dung. Assuming the pots to be about 6 in. deep, this would correspond with an application of about 125 tons of dung per acre mixed with the soil to the same depth.

There seems to be no doubt that the loss of nitrogen is caused by micro-organisms which occur in dung, in cereal straw, and, to some extent, in the soil. The power of liberating free nitrogen diminishes with the age of the dung, and Wagner thinks that the greater value of rotten, as compared with fresh manure is largely due to its diminished power of destroying the nitrates present in the soil. Addition of about 3 per cent. of superphosphate and kainite, respectively, to dung, increased its denitrifying power, both when the dung was turned over and when stored without turning over.

A large number of interesting results have already been obtained by the investigators already named, and by Stutzer, Pfeiffer, and others.—N. H. J. M.

*Manure, Manufacture of, from Waste Leather and Phosphate of Lime.* W. E. Rowlands, Seacombe, Chester. Eng. Pat. 17,926, July 30, 1897.

THE leather is moistened, a "suitable ferment" added, and the material is piled in mass until it becomes disintegrated by fermentation. Five parts of fermented leather are then mixed with 8 parts of crude phosphate of lime in a mixing machine along with sufficient  $\text{H}_2\text{SO}_4$  to decompose the phosphate.—J. T. W.

### XVI.—SUGAR, STARCH, GUM, Etc.

*Indeterminate Losses in Cane-Sugar Factories.* H. Pellet. Bull. Assoc. Chim. 1897, **14**, 1159—1162.

According to the theory of Prinsen-Geerligs (this Journal, 1897, 638), that in ripe canes the whole of the reducing sugar consists of dextrose, the direct polarisation would indicate too much sugar by 0.50 to 0.60 per cent., and as by the analysis of molasses in the ordinary way less sugar is found than really exists, the double error would amount to very high indeterminate losses.

The author has made tests in various factories during the past four years, and finds that with Egyptian canes of the first and second year, frequent analyses being made during the whole period of manufacture, the direct polarisation is the same as the polarisation by inversion, or slightly less, but never higher. The lower or older, and therefore riper internodes, show both less reducing sugar and less levulose, but levulose is always present. The indeterminate losses under proper control reach a maximum of only 0.20 per cent.

It would be interesting to know if the canes worked in Java contain more dextrose in proportion to reducing sugar than the red canes of Egypt, and on what this difference depends.—L. J. de W.

*Molasses, Incipient Carbonisation or Combustion of.* J. T. Crawley. J. Amer. Chem. Soc. 1897, **19**, 538—542.

THE molasses in question was boiled to what is known as "string proof," at a temperature of  $71^\circ$  to  $74^\circ$ , and run into an underground cistern from time to time, until the material was within six or eight inches of the top of the cistern, when the walls cracked, and the molasses began to leak out. It continued to leak for about one and a half months, during which time five or six feet was thus lost. That which remained seemed to be in a perfect condition. Five days later, however, it was found flowing over the sides of the cistern showing signs of incipient carbonisation. The temperature at the point where it flowed over was  $92^\circ$ , but in the cistern, and especially where the crack was located, this

boiling seemed to be more violent. This flowing continued for about 12 hours, but the molasses continued boiling within the cistern until there was left only a few feet of charred mass. The fumes given off affected the eyes considerably, and coming into contact with the metal roof, formed a salt.

The following substances were detected in the sample of char, the percentage being given where it was estimated: Organic acid, distilled, 3.8 per cent., calculated as acetic acid. Furfural and furfural yielding substances, minute quantities; glucose-yielding substances, small quantities, and caramels large quantities. Reducing sugars, 11.20; nitrogen, 0.87; phosphoric acid, 0.30; potash, 2.27; insoluble in water, 38.20; and moisture, 15.00 per cent. The sample of salt from the metal roof was almost pure zinc acetate, with a little formate.

The author attributes the phenomenon to incipient carbonisation. It is known that if molasses of low grade be boiled at a high temperature and run into coolers, it is very apt to froth and run over the sides of the containers; moreover, successive runnings of hot molasses into the coolers will often result in a burning of the product. Although the cause of this is not positively known, the author is of opinion that in the majority of cases it is due to decomposition of the non-sugars.—D. B.

*Sugar Content of Some Tropical Fruits, Determination of.* H. C. Prinsen-Geerligs. Chem. Zeit. 1897, **21**, 719.

See under XXIII., page 939.

*Beetroot Juice, Effect of Grease on the Filtration of Carbonated.* R. Schiller. Bull. Assoc. Chim. 1897, **14**, 1178—1181.

AN average of the working of several factories gave 58 litres of diffusion juice per 50 kilos. of beetroots, and a consumption of grease equal to 0.0026 per cent. Adhering to these proportions a series of tests were made using 50 kilos of roots in each case. The greases tried were palm nut grease, rape oil, Russian mineral oil, and Dalmenbarest woolgrease. The differences in the rate of filtration were so small as to be absolutely insignificant.—L. J. de W.

*Beetroot Juice, Flask for the Polarisation of.* D. Sidersky. Bull. Assoc. Chim. 1897, **14**, 1170.

#### PATENTS.

*Starch and Gluten, Improved Process and Apparatus for the Production of, out of Cerealia and Legumines.* J. Keil, Halle, Germany. Eng. Pat. 17,444, July 24, 1897.

THE cereal and leguminous flours are mixed with water as usual, to which about 0.2 per cent. of hydrated oxide of calcium is added, and kneaded in a receptacle provided with S-shaped paddles and stirring paddles inclining upwards towards the shaft, a plate being attached to the same at the top to prevent the dough rising above this height. The reservoir surrounding the paddle arrangement is provided with a delivery device.

A quantity of from 25 to 50 kilos. is worked through within 30 to 45 minutes, the paddles turning with increasing speed, after which time the mass forms a salve-like mixture. This substance is then centrifugalised, when the starch separates in an absolutely pure firm state (prime starch), and the gluten is paste-like and contains all the nutrient matter of the flour, its consistency rendering it suitable as an addition to human food.—L. J. de W.

*Crystallisable Liquids [Sugar Juice], Impts. in the Granulation of, and especially of the By-products of Sugar Manufacture.* J. Grosse, Kiew, Russia. Eng. Pat. 23,318, Oct. 20, 1896.

THE contents of the vacuum or granulating pan are heated, in the lower layers only, by a coil of piping through which steam or other heating agent is caused to pass, and a mechanical stirring device in the interior of the pan conveys the particles of the mass from the lower parts into the upper colder layers, effecting a continuous rapid evaporation, so that crystallisation is considerably accelerated.

A cording as finer or coarser crystals are desired, rather quantities of the by-product are drawn into the apparatus in larger or smaller quantities. After the pan is filled to about seven-eighths of its capacity, heating is discontinued, but the mass is still further agitated in the vacuum until the requisite cooling and the final crystallisation are effected.—L. J. de W.

*Starch Preparation, An Improved, and Process of Making the same.* R. Ausorge, Halle-on-Saale, Germany. Eng. Pat. 586, Jan. 8, 1897.

The present invention allows of starch being directly employed for laundry purposes in a cold state without previous boiling.

The starch is mixed with a suitable amount of zinc-white, or like filling material, and then borax and stearin, stirred up in hot water, are poured into it, and the whole is stirred together, and the starch dried.

The proportions preferably employed are:—30 grms. of white oxide of zinc, 15 grms. of stearin, 300 grms. of borax, and 1 kilo. of starch. The filling may be omitted.

Manufacturers can advantageously use the still wet starch obtained in the course of manufacture without previously drying it. A modification consists in the use of wheat flour instead of, or in addition to, raw starch.

—L. J. de W.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Wort, The Influence of the Malt Husk on the Extract, Colour, and Taste of the.* L. Freis. Wochenschr. für Brauerei, 1897, 502.

ROTHENBUCHER'S method for mashing malt flour, the husk being previously separated, has long been known to be impracticable, owing to the difficulty of obtaining a bright wort; but this led the author to inquire as to what effect the husk produces in the mash. He investigated this in the laboratory, and found that a pale malt gave 17.7 per cent., and a dark malt 18.7 per cent. of husk. The husk yielded 13 per cent. of extract; and as the malt yielded 71 per cent. of extract, 2.4 per cent. of this was due to the husk. The husk wort possessed a large proportion of the colour of the malt, the wort from the malt flour being very pale. The husk wort is sweet and insipid; about 50 per cent. is fermentable.—A. L. S.

*Beer.* Albuminoid Matter in two Brewings on the Wahl and the Windisch Systems. M. Henins and G. Thevenot. La Bière, 5, [7], 100—102.

THE two brews were prepared from equal quantities of materials, but the initial mashing temperatures differed, that in the Wahl method being 41.25° C., whilst in the Windisch method it was 75° C. The resulting worts also differed, containing respectively: extract, 12.06 and 11.68 Ball.; maltose, 8.61 and 8.68 per cent.; and a maltose ratio of 1:0.40 and 1:0.70. The Wahl wort broke exceedingly well, and, after fermentation, contained 4.688 per cent. of actual residual extract, and 3.8 per cent. of alcohol, the actual attenuation being 61.4 per cent.; whilst the other broke badly, and was very turbid when cold; and the figures for the above data were respectively 6.254, 2.87, and 16.5 per cent.

On subjecting the beers to analysis and precipitating the coagulable nitrogenous matter, the peptones, and albumoses, it was found that the Wahl process yielded a larger quantity of each than the Windisch process, viz., total N, 5.63 (4.08); true peptones, 0.76 (0.44); albumoses, 0.87 (0.84) per cent. of the extract. Hence the authors conclude that if the production of "head" be, in fact, due to bodies of such nature, the end will be more satisfactorily attained by means of a low initial mashing temperature than by the converse method.—C. S.

*Albuminoid, Structureless, Present in Admixture with Bottom-Fermentation Yeast.* [Brewing.] H. Will. Zeits. für d. ges. Brauwesen, 20, [35], 447—449; [36], 459—462; [38], 485—488.

On thoroughly shaking up fresh bottom-fermentation yeast in a test tube with ether, a gelatinous mass is formed, which

after standing (closed) for some days, separates into two layers: a lower stratum of pale yellow liquid and an upper grey-brown vitreous layer. The difference is more sharply accentuated if the ether has been previously stained with alkanin, the gelatinous layer in that case, absorbing the colouring matter. When this portion is examined under the microscope, it is found to contain, in addition to yeast cells and fragments of grains, hops, &c., a network of gelatinous matter binding the whole together and also enclosing drops of ether, many of the latter being surrounded by an integument which shrivels up as the ether evaporates. This skin answers to all the reactions characteristic of albumin, and is rendered particularly conspicuous when treated with Millon's reagent or by the Raspail method (concentrated sugar solution and sulphuric acid).

On the other hand, the gelatinous matrix is not stained by iodine or by aniline dyes, but, when treated with water, it swells up and dissolves, liberating the yeast and other embedded substances; sulphuric acid causes it to thicken, as also Millon's reagent does. Fehling's solution gives no precipitate. From tests performed on the washings from several yeasts, this gelatinous matrix is believed to consist mainly of gum.

The capacity of yeast for permanently absorbing ether was also examined by the author. He finds that it varies in different yeasts, and also in the different strata—e.g., "core" yeast and superficial layer—of one and the same yeast, the average absorption per 6 c.c. of yeast of normal constitution ranging from 10 to 12 c.c. of ether for the "core" yeast, and from 13 to 18 c.c. for the upper layers. In proportion as the yeast is freed, by washing, from the substances assisting in the formation of bubbles of ether, the capacity of permanent absorption is reduced, but is restored by the addition of mucic acid and peptone, these bodies gelatinising under the ether treatment. The amount of water present is a measure of the distension of the albuminoids, which factor in turn governs the absorption of ether.

When the washings from the yeast were united and shaken up with ether, a supernatant stratum of thick emulsion, containing bubbles of ether, separated out. The amount of this emulsion in the individual washings progressively decreased, and at about the tenth washing ceased to form.—C. S.

*Red Wines, Fermentation of Deeply Coloured; Influence of Colouring Matters on the.* P. Carles and G. Nivière. Comptes Rend. 1897, 125, [12], 452—453.

THE authors arrive at the following conclusions:—(1.) The incomplete transformation of sugar in highly coloured worts is due to the colouring matter and not to the acidity, since decoctions of elder, whether acidified or not, have given the same result. (2.) The colouring matter, allied to tannin, acts as an antiseptic on the micro-organisms which produce fermentation.

Tartaric acid, added to red wines, has no influence on the fermentation, or, if it acts at all, it is only indirectly in preventing the precipitation of the colouring matter, which itself acts on the ferments.—J. S.

*Lactic Fermentation, Contribution to the Study of.* H. Pottier. La Bière, 5, [9], 136—140.

THE object of the investigations undertaken by the author, was to ascertain whether any close optical relation exists between a sugar and the lactic acid resulting from its fermentation. The ferment employed was obtained, by dilution, from the juice of onions self-inoculated in air. It grows best at 35° C. and in a medium of onion juice, to which 0.5 per cent. of peptone has been added.

The acid obtained from the fermentation of lactose was optically inactive so long as the proportion of peptone taken remained above 1 per cent., but when this ratio was reduced, a mixture of inactive and sarcosolactic acids resulted, without the ferment losing its activity. Saccharose yielded inactive lactic acid, whilst maltose yielded the inactive acid in presence of 1 per cent. of peptone, but the dextro-rotatory acid with 0.6 per cent. of peptone. The results obtained with glucose, invert sugar, galactose, and mannose were on similar lines, whereas mannite, dulcitol, and glycerin (which

offer greater resistance to the ferment) all furnished active (dextro-) acid. With these latter bodies, fermentation proceeded very slowly, and was not hastened by an increase of peptone. Calcium malate was attacked by the ferment, but only alcohol and volatile acids resulted. Neither lactate, succinate, nor tartrate of calcium is, however, acted upon.

The author concludes that a lactic ferment may, without prejudice to its qualities as a true lactic ferment, produce active lactic acid equivalent to over 80 per cent. of the sugar eliminated. Also that the optical properties of the acid are independent of the composition and properties of the original carbohydrate, but that a number of factors come into play, the diminution of the nitrogenous nutriment, an increase in temperature, the addition of antiseptics and the greater resistance of the hydrocarbons, all tending to the production of dextro-rotatory acid.—C. S.

*Mead, The Natural Ferments of.* E. Kayser and E. Boullanger. *La Bière*, 5, [8], 113—121; [9], 129—135.

THE conclusions arrived at by the authors from their extensive researches, may be summarised as follows:—

The honey worts should be prepared in such a manner as not to indicate a greater strength than 24—25 per cent. of sugar by the Guyot glucometer (13° B.) for dry meads, or 26—27 per cent. Guyot (14—14.5° B.) for sweet meads. Filtration is always advisable especially when working with selected yeasts; and is essential to the production of good mead in the case of waxy honey.

To ensure the normal and rapid progress of fermentation, diminish the risk of infection by injurious organisms, and produce a liquor of excellent quality and endowed with good keeping properties, the addition of one of the following yeast foods is necessary:—A.: Maltopeptone 1.5 c.c., potassium bitartrate 1 gm. per litre; B.: Maltopeptone 1.5 c.c., potassium bitartrate 1.5 gm., ammonium phosphate 1.0 gm. per litre; C.: Spongy peptone 0.12 gm., potassium bitartrate 1.5, ammonium phosphate 1.5 gm. per litre; X.: Calcium biphosphate 1 gm., ammonium phosphate 2.0, potassium bitartrate 2.0, magnesium sulphate 0.1 gm. per litre. The nutritive mixture is dissolved in a few litres of the wort and then well mixed up with the bulk.

In starting the fermentation, it is highly desirable to prepare the yeast by pitching 1 or 2 litres of sterilised wort, containing nutritive material, and leave it to ferment for a couple of days, after which it is transferred to the main body of wort. This procedure is of particular service (in cases where no yeast food is used) for developing a vigorous pitching yeast.

Selected wine yeasts will give excellent results and improve the quality of the product, their behaviour being superior to that of other yeasts when the fermentation temperature is high. Pollen yeast may be recommended, provided it has been subjected to the preparatory treatment named above.

Provided the temperature be favourable, the brisk primary fermentation should not last more than a month. Rousing is desirable when the fermentation slackens before the proper quantity of sugar is consumed.

Secondary fermentation is a protracted and delicate operation in the case of meads, and should continue for several months in order that a good product may result. Dry meads should be transferred to a cellar when primary fermentation is completed, and there left for the yeast to finish its work slowly and to clarify. Sweet hydromels, on the other hand, should be racked to remove the greater part of the yeast, and then fined. This last operation will be easier in proportion as the fermentation has been brisk and regular.

It should take about six months to produce a good saleable article; but, as already stated, primary fermentation ought to be complete in one month, at the end of which time dry meads should indicate not more than 2—3 per cent. of sugar, and sweet meads a maximum of 4—6 per cent. by the Guyot instrument. The liquor must not be bottled until perfectly clear.—C. S.

## PATENTS.

*Fermented Liquors, The Manufacture of.* Impts. in. J. Schneide. New York, U.S.A. Eng. Pat. 27,852, Nov. 17, 1896.

THIS invention relates to fermented liquors, such as beer, cider, &c., but has special reference to the manufacture of lager beer. It is customary to transfer lager beer, after fermentation, from the fermenting tuns at a temperature of 3—4—13° C. to the storage casks, where, the cellar being maintained at about 1—2.5° C., it gradually cools down and slowly deposits (six weeks or more) those albuminoid constituents which are coagulable at a low temperature. The improvement consists in cooling the beer to 0° C. before transferring it to store-casks. By this means, it is claimed, the albuminoids are immediately thrown out of solution and caused to settle in a comparatively short space of time. In its application to cider, &c., the process is similar, i.e., the liquor is stored at a low temperature until brilliant.—H. T. P.

*Yeast, The Manufacture of; Impts. in and relating to.* (Apparatus.) H. H. Lake, London. From L. S. Langville and H. Tauszky, New York, U.S.A. Eng. Pat. 18,112, Aug. 3, 1897.

A process and apparatus for separating yeast from fermented liquids, in the manufacture of pressed yeast. The apparatus consists of a number of shallow troughs, connected in series and communicating by valves or slides. The liquid containing yeast in suspension is allowed to flow through the troughs, and being cooled during its passage by a refrigerating system arranged beneath, and in contact with the troughs, rapidly deposits its yeast. If desired, a separation of the yeast into two or more grades ("strong" and "weak") may be secured, by reason of the fact that the strong cells are deposited at an earlier stage than the weak ones.—H. T. P.

## XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A).—FOODS.

*Fermentation, Quick versus Slow.* [Bread Baking.] W. Jago. *National Assoc. Rev.*, Aug. 1897, 487—493.

THE conditions which accelerate fermentation are—strong yeast, soft flour, use of potatoes and saccharin extract (which act as stimulants), slackness of the dough (water), aeration, and primarily a high fermentation temperature. Fermentation is retarded by the reverse of these conditions and also by the use of large quantities of salt. In order to determine by which method the souring of the bread was best held in check, the author made experiments in which 50 grms. (1.8 oz.) of flour and 200 grms. (7 oz.) of water were fermented with 2.5 grms. (say  $\frac{1}{10}$  oz.) of distillers' yeast and 10 grms. (say  $\frac{3}{10}$  oz.) of brewers' yeast respectively. The fermentation was continued until about 350 c.c. of gas had been evolved, and the acid produced reckoned as grms. of lactic acid.

	Time Taken.	Acid produced.
	Hours.	
Distillers' yeast, 75° F. ....	10½	0.219
" " 95° F. ....	3½	0.115
Brewers' " 75° F. ....	11	0.196
" " 95° F. ....	6	0.214

## Repeats on Second Day.

Distillers' yeast, 75° F. ....	11½	0.225
" " " 95° F. ....	4	0.180
Brewers' " " 75° F. ....	11	0.522
" " " 95° F. ....	5½	0.513

In the author's opinion these results prove that, for the same amount of fermentation, the amount of acidity produced at a comparatively high temperature is "at least not higher" than that produced at a much lower temperature; and, from a similar series of laboratory experiments, he also draws conclusions in favour of the quick fermentation process.

Further experiments on a larger scale in the bakery are described, which seem to prove that from 3¼ to 3½ hours at 91° F. is the most suitable time for a quick fermentation. When the working time is shortened to three hours, the results are unsatisfactory, even when the temperature and amount of yeast are increased. With a quick fermentation process, less plant is required, and the dough does not remain so long exposed to atmospheric conditions, and while more yeast is required, there is an increased yield of bread. On the other hand, the sponges and doughs must be taken at exactly the right time, or the whole batch may be spoiled.—C. A. M.

*Earth-Nut, Detection of, in Chocolate.* Biltz, *Chem. Ztg.* 1897, 447; through *J. Pharm. Chim.* 1897, 6, [1], 29.

See under XXIII., page 937.

## PATENTS.

*Aeration and Preservation of Milk, and Apparatus therefor; Impts. in the.* R. G. Nash, Doldin. Eng. Pat. 14,209, June 26, 1896.

THE milk is heated to a temperature of 156° to 160° F., whereby it is sterilised, and then cooled. When thus treated, it is then charged with sterilized gas, decanted, and heated in a closed vessel to 150°–212° F. On cooling, a sterilised, aerated beverage is obtained. The gas is sterilised by passing it through a coil maintained at a red heat, thence through a coil submerged in cold water, and then through sterilised water or other purifying liquid. An improved method of flavouring aerated liquids is claimed, consisting in adding the flavouring material to the washing water employed in sterilising the gas, whereby the flavour is imparted to the gas. To prevent the milk curdling, an alkali and sugar are added. A creamy "head" on the milk is obtained by the addition of a suitable essence.

—W. P. S.

*Horse and Cattle Food, A New Manufacture of.* W. C. Forsyth, Leytonstone, Essex. Eng. Pat. 25,344, Nov. 11, 1896.

THE claim is for a food consisting of a mixture of linseed, oats, locust beans, and maize, together with small quantities of spices and salt.—W. P. S.

*The Preservation of Organic Matters [Foodstuffs], Impts. in.* J. J. Hazard, London. Eng. Pat. 899, Jan. 12, 1897.

THE process claimed is one for preserving organic substances, such as carcases of beef or mutton, poultry, game, fruit, furs, eggs, &c., by subjecting them to the action of dry carbonic acid under pressure, and afterwards storing them in hermetically closed chambers, the atmosphere of which is kept dry by means of a suitable drying agent and agitation. It is usually found sufficient to expose the body in the pressure chamber for 20 to 40 minutes at a pressure of from 2 to 5 atmospheres.—W. P. S.

*Milk, Impts. in Treating.* A. Bernstein, Boston, U.S.A. Eng. Pat. 14,336, June 12, 1897.

THE object of this invention is to prepare an edible product from skimmed or separated milk. For this purpose, a quantity of wheaten or other flour is added to the milk, which is then coagulated by the addition of rennet. After

draining off the whey, the curd is obtained as a soft mass, which may be dried to a powder, and mixed with flour for baking purposes.—W. P. S.

*Edible and Soluble Tablets, and the Method of Producing the same, Impts. in.* H. Horlick, Racine, Wisconsin, U.S.A. Eng. Pat. 16,088, July 6, 1897.

THE tablets consist of pasteurised milk combined with the extract of crushed barley malt and the extract of pulverised cereals, prepared as described below, and pressed into a dry solid form.

Equal quantities of coarsely broken or crushed barley malt and wheaten or other flour are macerated in cold water. The temperature is then raised to about 160°–165° F., and the mash kept in agitation until it becomes thin enough to filter. After filtering, an equal quantity of cows' milk is added to and thoroughly mixed with the extract. The resulting product is pasteurised, and then evaporated *in vacuo* until it is practically dry. It is then removed and pressed into moulds. Before the mixture is quite dry, 5 to 15 per cent. of either cocoa, chocolate, or beef tea may be added, and the drying continued as before.

—W. P. S.

*Preservation of Lobsters and other Crustacea packed in Metal Cans or other Receptacles, Impts. relating to the.* L. Wurzburg, London. Eng. Pat. 17,914, July 30, 1897.

THE method or process claimed, consists in dipping the crustacea-meat, and the metal cans or other receptacles, into a solution of boric acid. Each pint of preserving solution should contain two ounces of boric acid. After dipping, the tins are sealed up as soon as possible and put through the usual bath.—W. P. S.

## (B.)—SANITATION; WATER PURIFICATION.

*Acetylene, Poisonous Action of.* U. Mosso and F. Ottolenghi. *Ann. di Chim. e di Farmacol.* 25, 163.

THE authors have studied the poisonous action of mixtures of acetylene and air. Small amounts of acetylene are dangerous to animals. Inspiration of ½ litre of the pure gas poisons dogs in a few seconds, and powerful artificial respiration is need to restore them. A 20 per cent. mixture of acetylene and air kills dogs in an hour or less; the disturbance to the system is so great in these slow actions, that the dogs often die after they have been brought into fresh air and have apparently recovered. Large amounts of the gas affect the respiration; smaller quantities produce irritation, followed by a period of paralysis and weakening of the heart and lungs.—J. T. D.

## PATENT.

*Putrefaction of Bodies [Corpses]; Improved Method of and Apparatus for preventing the; also applicable for Disinfecting Mattresses, Articles of Dress, and the like.* F. de Rechter and G. de Rechter, Brussels. Eng. Pat. 15,368, June 26, 1897.

THIS specification describes an arrangement of apparatus for disinfecting by means of formalin. The apparatus consists of a large disinfecting, and a smaller generating chamber, both of which can be suitably heated. The formalin solution is delivered from a drop-feeding cup on to the surface of stretched plaited lamp wick or other absorbent material, contained in the generating chamber, where it evaporates and by means of top and bottom flues connecting the two chambers, one of which contains a revolving fan, the vapour is caused to circulate. An air-pump is provided, by means of which the atmosphere of the apparatus can be rarefied, and the disinfecting chamber contains a perforated tube filled with calcium chloride for drying the air. When disinfection is judged to be complete, the connecting flues are closed by means of shutters; and the calcium chloride tube is replaced by another tube containing absorbent material saturated with a neutralising liquid, such as ammonia, which absorbs the residual aldehyde vapour and renders the atmosphere respirable when the chamber is opened.—L. A.

## (C).—DISINFECTANTS.

*Alcohol as a Disinfecting Agent.* F. Epstein. Proc. Inst. Civil Eng. 1896-97, **129**, [3], 31; Zeits. für Hyg. 1897, 1.

THE author found that absolute alcohol had no disinfecting action, but that its solutions were more or less active, according to the degree of concentration. 50 per cent. solutions gave the best results when alcohol was used alone; the disinfecting action was diminished when more concentrated or more dilute solutions were employed. Antiseptics which, when dissolved in water, were more or less active, lost their disinfecting action entirely when dissolved in highly concentrated alcohol; but, on the other hand, solutions of corrosive sublimate, carbolic acid, "lysol," and thymol in 50 per cent. alcohol, exerted greater powers than aqueous solutions of the same degree of concentration.—A. S.

## PATENTS.

*Disinfecting Purposes, Impts. in and relating to Materials and Apparatus for.* R. Goehde and H. Oppermann, Berlin. Eng. Pat. 20,901, Sept. 22, 1896.

FORMIC aldehyde and menthol are dissolved in methyl alcohol, and the solution is placed in a dropping bottle, which is supported in an inverted position over a concave disc of asbestos fixed at the top of a sheet-iron chimney surrounding the flame of a lamp. The drops of solution falling upon the heated asbestos are rapidly evaporated and diffused throughout the surrounding air, which is thereby disinfected.

The solution is preferably saturated with formalin, but the proportion of menthol may vary from 1 to 50 per cent., the larger proportion being used in order to neutralise the action of the aldehyde on the mucous membrane, when the atmosphere is being respired by persons during the process of disinfection.—L. A.

*Disinfecting, Impts. in, and in Apparatus Therefor.* A. Zimmermann, London. From The Chemische Fabrik auf Actien vormals E. Schering, Berlin. Eng. Pat. 26,667, Nov. 24, 1896.

DRY paraformaldehyde in the form of pastils is placed in a metallic cup, which fits in the upper part of a chamber surrounding the flame of a spirit lamp, so constructed that the products of combustion are made to pass through orifices in the upper sides of the cup, and become mixed with the vapour of the aldehyde, which is in this manner largely diluted and mechanically diffused into the atmosphere of the place to be disinfected. The water vapour contained in the combustion gases is essential for the proper development of the disinfecting action of the aldehyde, and the rate of evaporation is such that 1 grm. of paraformaldehyde becomes diluted with 9 grms. of carbon dioxide, and about  $3\frac{1}{2}$  grms. of steam.

Instead of paraformaldehyde, asbestos saturated with an aqueous solution of ordinary formaldehyde may be employed.—L. A.

*Bursting of Bottles and other Receptacles while Substances enclosed therein are being Sterilised, Preventing the: Impts. in Methods of, and in Apparatus therefor.* A. L. Rockstrom, Norberg, Sweden. Eng. Pat. 16,952, July 17, 1897.

THE principle of the method is to maintain, during the whole time of heating and cooling, a pressure on the outside of the vessels equal to or slightly exceeding the pressure in the interior. This is accomplished by placing the vessels in a closed chamber, which is filled with a fluid, and by forcing into or withdrawing from the said chamber, water or a gas during the heating or cooling operation, an external pressure is maintained equal to or exceeding that which simultaneously exists in the interior of the vessels.—L. A.

*Compounds of Formic Aldehyde for Preserving, Disinfecting, and Therapeutic Purposes; Process for the Preparation of.* H. Oppermann, Berlin. Eng. Pat. 18,250, Aug. 5, 1897.

THE patentee has found that by the agency of ammonia, formic aldehyde may be coupled with any substance capable of combining with or dissolving in ammonia solution.

Crystalline compounds are thus produced (similar to the known compounds of aldehydes with bisulphites) in which formalin is united with substances having disinfecting, preserving, or specifically therapeutic properties. The bodies thus formed are fairly stable, easily soluble in water, and are powerful reagents. Thus, the compound of formalin with boric acid is said to be more efficacious than mercuric chloride; and the compound with phenol, when evaporated in small quantity, will disinfect a large space.

For the preparation of these bodies, the ordinary 40 per cent. solution of formalin, together with the required other substance, is dissolved in the requisite quantity of ammonia solution of 30 per cent. strength, with constant stirring and cooling. The compound either crystallises out, or is obtained by evaporating the liquid at a low temperature *in vacuo*. Substances mentioned are tartrates, boric and salicylic acids, and phenol; or triple compounds may be formed in which formalin is united with phenol and menthol, or with boric acid and tannin.—L. A.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Ozone, Production of.* Otto. Proc. Inst. Civil Eng. 1896-97, **129**, [3], 72-73. Mémoires et Comptes rend. des travaux de la Soc. des Ingén. Civils de France, March, 1897, 310.

THE author considers that the low theoretical efficiency in output (rather less than 2 per cent.) of the Siemens and Halske and Andréoli machines for producing ozone, is due to the employment of too high potential and a bad choice of dielectric. He has designed machines for the production of ozone, which, with a periodicity of 80 per second, give a theoretical efficiency of 15 per cent.; the output was found to be greater as the periodicity of the working current increased, and also as the velocity of the current of gas through the machine was increased. The machines are of four types, but the general arrangement in all is one of plate conductors, protected either on one or both sides with dielectric, arranged alternately of opposite sign and with an air-space between, through which the gas to be treated is passed, and across which the electric discharge takes place. In some cases the gas is drawn in at the edges of the plates, and delivered through a central aperture on one side; and in others it is drawn in and delivered at central apertures, one on each side.—A. S.

*Sulphur Precipitatum (American).* T. D. Reed, M.D. Amer. Pharm. Assoc. 1897; through Pharm. J. 1897, **59**, [1421], 265.

AN examination of trade samples of precipitated sulphur, obtained in Canada and in the United States, show that more than half (29 out of 55) contained calcium sulphate.

—J. O. B.

*Selenium in Commercial Sulphur.* T. D. Reed. Amer. Pharm. Assoc. 1897; through Pharm. J. 1897, **59**, 261.

See under XXIII., page 935.

*Turpentine, Action of Sulphuric Acid on Levo-rotatory.* G. Bourchardat and J. Lafont. J. Pharm. Chim. 1897, **6**, 193-196.

LEVO-ROTATORY French essence of turpentine was treated with 10 per cent. of sulphuric acid and the product heated at 150° with alcoholic potash in excess. On addition of water, a light oil was obtained, containing unaltered turpentine, camphene, terpenes, and their solid and liquid polymers, together with a small quantity of levo-rotatory

borneol and its dextro-rotatory isomer melting about 50°. The aqueous solution contains two potassium salts of the formula  $C_{10}H_{15}KHSO_4$ ; these were separated by fractional crystallisation from alcohol. The less soluble is a salt of the acid sulphuric ether of levo-rotatory borneol or of an isomer; it is itself levo-rotatory. The more soluble salt is dextro-rotatory, it is derived from dextro-rotatory fenchol.

—A. C. W.

*Iodoform, Electrolytic Preparation of.* K. Elbs and A. Herz. *Zeits. f. Elektrochem.* 4, [4], 1897, 113—118.

AN electrolytic process for preparing iodoform, bromoform, and chloroform from the corresponding halogen compounds of the alkalis and alkaline earths in presence of alcohol, aldehyde, or acetone, has been known and patented since 1884 (E. Schering, Berlin). The authors have studied more closely the nature of the electrolytic processes and the conditions which give a good yield. The following equation represents the reaction of iodine upon warm alcohol in the presence of an alkali or alkaline carbonate:—

The reaction can be conveniently carried out by passing an electric current through an aqueous solution of potassium iodide and soda mixed with alcohol—the current setting free from the potassium iodide the ions iodine and potassium. The hydriodic acid (or potassium or sodium iodide) formed by a secondary reaction is again decomposed by the current; thus the iodine not combined with carbon is for the most part regenerated continuously, and only a small part of it is converted at the anode into potassium iodate. Conditions might exist under which the oxidation might stop short of producing carbon dioxide, and might instead only produce formic acid—

But in the electrolysis carried out by the authors, no trace of formic acid was ever observed. The theoretical yield is therefore calculated according to equation (1), and amounts to 1.468 grms. of  $CHI_3$  per ampère-hour. The actual yields are expressed as percentages of this. Five tables are given illustrating the influence of various conditions on the yield. Table A illustrates the effect of temperature: the yield is best when the temperature is between 60° and 70° C. Table B shows (other things being equal) that when the proportion of soda present is increased, the yield of iodoform slightly falls off, while there is a marked increase in the amount of iodic acid formed. When the soda is kept constant and the amount of potassium iodide is increased, the yield of iodoform increases and the amount of iodic acid decreases (Table C). Similar effects are produced when the soda and potassium iodide are kept constant and the amount of alcohol is increased. Table E illustrates the effect of varying current-density. The results show that the current-density should not exceed 1 ampère per square decimetre. 60 is a suitable temperature, and the electrolyte should be made up in the proportion of 5 or 6 grms. of anhydrous sodium carbonate, 10 grms. of potassium iodide, 20 c.c. of alcohol, and 100 c.c. of water. The precipitated iodoform should be removed hourly, and the electrolyte made up to the original composition by adding soda, potassium iodide, and alcohol. Iodic acid is only formed slowly, and is of secondary importance; it takes a long time before it accumulates sufficiently to interfere with the main reaction. The yield is excellent. In the third ampère-hour the yield amounted in one experiment to 97.3 per cent., and in another to 97.7 per cent. of the theoretical. The iodoform was crystalline, only very slightly coloured (yellow), and perfectly pure.—D. E. J.

*Orthoform: A New Local Anesthetic.* A. Einhorn and R. Heinz. *Munich Med. Woch.* 1897, 14, 931; through *Pharm. J.* 1897, 59, [1422], 277.

THE new synthetic body, which possesses marked anæsthetic properties, and is at the same time relatively nontoxic, and also antiseptic, promises to find a place as a therapeutic agent. Experiments of previous workers show that none of the products obtained by splitting up the cocaine molecule are capable of producing anæsthesia, and

that this action is possessed only by those compounds, analogous to cocaine, in which the ecgonine esters are combined with certain acid radicles. In this respect, the group  $COOH \cdot C_6H_5$  appears to play a very important part. This anæsthetic property was found to be possessed by all amido-oxy esters of the aromatic series, but the body from which these are all derivable—the amido-oxybenzoic ester—has this action in a still greater degree. After trial with a large number of these bodies, the *p*-amido-*m*-oxybenzoic methyl ester was found to give the most satisfactory results, and this is therefore introduced for therapeutic use under the name of orthoform.

It occurs as a white bulky crystalline powder, melting at 120° C., non-hygroscopic, and but slightly soluble in water, so that it is only slowly absorbed, and therefore produces a persistent anæsthesia. The hydrochloride is readily soluble in water, but as the solution has an acid reaction, it is not always applicable for hypodermic use.—J. O. B.

*Cinchonine, The Transformations of, by the Action of Acids.* Z. H. Skraup. *Monatsh. für Chem.* 1897, 18, 411.

By the action of hydrochloric acid on cinchonine hydrochloride, 25—30 per cent. of the base is converted into an addition compound, the remainder into the isomeric bases—iso- and pseudocinchonine. If this addition compound be the intermediate stage in the transformation, according to the hypothesis of Wislicenus, if it be subjected to the conditions which produced it, then there will be formed the same proportions of the isomeric bases as above. This was not found to be the case. Hence the transformations do not take place through the addition compound.

Attempts to convert cinchonine into isomeric bases by the action of hydrochloric or sulphuric acid were unsuccessful. The sulphates obtained from the fractionally crystallised products had the same solubility and the bases the same rotation, though the salts differed in appearance. Now cinchonine probably differs from cinechonine only in containing an ethyl- in place of a vinyl-group ( $-CH \cdot CH_2$ ). Thus the transformations of cinchonine must be referred to changes in the vinyl-group.—A. C. W.

*Retamine: A New Alkaloid.* Battandier and Malosse. *Journ. Pharm. Chim.* 1897, 6, (6), 211.

FROM the young branches and bark of *Retama sphaerocarpa*, the authors have isolated an alkaloid, retamine, having the composition  $C_{13}H_{16}N_2O$ , which appears to be an oxysparteine. From a saturated solution in petroleum ether it crystallises in long needles; from alcohol, on cooling the saturated solution, it separates in lamellæ, by spontaneous evaporation from the same solvent in fine rectangular tablets. The taste is bitter, and the alkaloid is without marked physiological action. The crystals melt at 162° C., with alteration, and at a higher temperature, decompose, giving a crystalline sublimate, and evolving a pyridine-like odour. Retamine acts as a powerful base, colouring phenolphthalein, displacing ammonia, and precipitating the salts of iron and copper. It also acts as a powerful reducing agent; gold chloride and phosphomolybdic acid are immediately reduced by it, silver salts and potassium ferricyanide more slowly; mercuric chloride is transformed to calomel by its action. It gives all the alkaloidal reactions, but does not precipitate with platinum perchloride. Its salts crystallise very easily, with the exception of the nitrate. In absolute alcohol at 17° C. its solubility is 2.462 in 100. The specific rotation is  $(\alpha)_D = 43.2^\circ$ .—J. O. B.

*Cinnamic Acid from Storax and Benzoic Acid from Benzoin, Extraction of.* E. Classen. *Pharm. Rev.* 1897, 15, 136; through *Chem. Zeit.* 1897, 21, 199.

STORAX is boiled for some time in a copper vessel with an excess of sodium carbonate solution. When cool, hydrochloric acid is added until the reaction is only faintly alkaline. The mixture is again heated to boiling and filtered, and the residue washed with water until exhausted. The mixed filtrates are precipitated with an excess of hydrochloric acid. The precipitate is collected, washed

with cold water, dried and extracted with hot benzene. On cooling, the greater part of the cinnamic acid separates out. The benzene is distilled off and used for further extractions as long as anything is dissolved. Finally, the benzene solution of the acid is shaken out with dilute sodium carbonate solution, and the acid re-precipitated from this with hydrochloric acid, washed with cold water on a filter, and dried. The acid thus obtained from the first extraction is brilliantly white, but subsequently is coloured yellowish; when this occurs, the coloured acid is redissolved in benzene and again extracted, and precipitated as above. The same process is applicable to certain varieties of benzoin, for the extraction of benzoic acid, and also for the separation of benzoic and cinnamic acid from Tolu balsam.—J. O. B.

*Parathyroid Glandules, Presence of Iodine in.* F. Gley. Comptes rend. 1897, **135**, 313.

The small parathyroid glandules which are found accompanying the larger true thyroid glands, are stated to be relatively richer in iodine in the case of dogs and rabbits than the latter bodies. It is evident therefore that, if the presence of a secretion containing iodine is to be considered distinctive of the thyroidal class of organs, the smaller parathyroid glands must be included with them. And further, that if this secretion be the active principle of the gland, that the parathyroid glandules must be, at least as potent, weight for weight, as the true thyroid.—J. O. B.

## PATENTS.

*Terebenthene Monohydrochloride, Impts. in the Manufacture and Application of.* J. G. McIntosh, London. Eng. Pat. 21,031, Sept. 22, 1896.

IN the process claimed, the mixture of solid and liquid hydrochlorides obtained by the saturation of turpentine with hydrochloric acid gas, is distilled with the addition of caustic alkali. The combined distillates are filtered and cooled to separate the solid from the liquid hydrochloride. The use of either of the hydrochlorides, or a mixture, as a substitute for natural camphor in the manufacture of celluloid, soaps, antiseptics, &c., is also claimed.—A. C. W.

*Pharmaceutical Compound [Codeine], Impts. in the Production of.* Farbenfabriken vormals F. Bayer and Co. Elberfeld, Germany. Eng. Pat. 24,799, Nov. 5, 1896.

IN the methylation of morphine by means of methyl iodide or methylsulphuric acid, considerable quantities of the alkaloid remain unchanged. The patentees claim the production of codeine from morphine and diazomethane or such substances as are capable of yielding diazomethane, with or without the presence of alkalis, and they also claim the use of nitrosomethylurethane as the source of diazomethane in the process first mentioned.—A. C. W.

*Piperazine Salicylate, Manufacture of.* La Société Chimique des Usines du Rhône, Lyons, France. Eng. Pat. 25,905, Nov. 17, 1896.

PIPERAZINE salicylate,  $C_4H_{10}N_2[C_6H_4(OH)COOH]_2$ , is claimed as a new product, and the processes for its manufacture, which consist in mixing boiling concentrated aqueous, alcoholic, or ethereal solutions of 1 mol. of base with 2 mols. of acid, or in melting the same ingredients together and recrystallising from one of the above solvents.—A. C. W.

*Nucleins, An Improved Preparation of, and Process for Making it.* J. Carnrick, New York, U.S.A. Eng. Pat. 17,610, July 27, 1897.

THE process claimed, consists "in dissecting the lymphoid tissues containing the largest percentage of nuclein from the muscular and other coarse tissues, drying the lymphoid tissues at a comparatively low temperature, not exceeding 130° F., then reducing the material to a powder, and separating the nuclein cellular matter from the sealy fibrous matter by sifting or other means. The nuclein cellular powder is then treated with a solution of a suitable gum, as benzoin, for protecting and preserving it." The product is also claimed as a new article of manufacture.—A. C. W.

*Acetone, Halogen Derivatives of; Impts in the Process for Preparing.* L. Lederer, Munich, Germany. Eng. Pat. 17,692, July 28, 1897.

IN the process claimed, iodine, ready formed or nascent, is made to react with acetonedichloroxylic acid, in the presence of substances which combine with or decompose hydriodic acid. The chlorine and bromine compounds are similarly produced with or without the presence of some substance to combine with the free acid produced. By using the proper proportions of iodine, per-, penta- or tetra-iodoacetone may be made.—A. C. W.

## XXI.—PHOTOGRAPHY.

### PATENT.

*Photographic Paper, An Improved Sensitised.* A. Schwarz, Gross Lichterfelde, Germany. Eng. Pat. 26,234, Nov. 20, 1896.

A "BROMIDE" paper, prepared by coating transparent paper—instead of opaque paper as heretofore—with silver bromide.—H. T. P.

## XXII.—EXPLOSIVES, MATCHES, Etc.

*Nitronaphthalene, the Commercial Preparation of.* W. H. Krug and J. E. Blomen. J. Amer. Chem. Soc. 1897, **19**, 532—538.

THE manufacture of nitronaphthalenes has of recent years acquired considerable importance, owing to the fact that their presence in nitroglycerin renders the latter practically non-sensitive to concussion, whilst even a small admixture prevents dynamite from freezing. Nitronaphthalene is also said to possess the property of rendering dynamite "fumeless," but this has not yet been definitely decided. It considerably increases the solvent action of nitroglycerin on nitrocellulose.

When the nitronaphthalene is used in conjunction with nitroglycerin, its melting point is of minor importance, but it is desirable to have as high a degree of nitration as possible, since this will retard the momentum of the explosion to a less extent. When used with other explosives, such as picric acid, the melting point must obviously be below the point of decomposition of the explosive agent. When it is desired to use a higher nitronaphthalene in this connection, it may be accomplished by adding a small amount of mononitronaphthalene, as the latter acts as a solvent of the higher nitro-derivatives, and they together will dissolve picric acid, nitrocellulose, and the like.

The nitro-derivatives of naphthalene are generally obtained either by the action of nitric acid alone or mixtures of nitric and sulphuric acids on naphthalene, or for the highest nitro-derivatives, by renitration of the lower nitro compounds. The author has made a number of experiments with a view of ascertaining the practicability of the proposition to prepare the higher derivatives by the nitration of naphthalene-sulphonic acid, similarly to the preparation of nitrophenols from phenolsulphonic acid.

$\alpha$ -Naphthalenesulphonic acid was prepared by heating naphthalene to 100° for about eight hours, with one, two, and three times the amount of sulphuric acid required by theory. A fourth preparation was made, using a large excess of sulphuric acid. A quantity of each of these acids, corresponding to 10 grms. of naphthalene, was treated in one series with 40 grms. of nitric acid of 36° B., and in

another series with 30 grms. of the same acid. The nitrations were effected on a water-bath and were considered complete some time after the red fumes ceased to come off. The product was melted under water and washed in this manner until free from acid. It was then carefully dried and weighed. The results showed that the two series corresponded quite closely in every respect, the yield decreasing proportionately to the extent of sulphonation. It is therefore impossible, under these conditions, to prepare nitronaphthalenes from  $\alpha$ -naphthalenesulphonic acid, although a higher degree of nitration is obtained than with pure naphthalene.

With regard to the preparation of nitronaphthalenes from naphthalene direct, the authors made a number of trials, which show that it is best to nitrate with a mixture of nitric and sulphuric acids, using about three times as much acid of 36 B. as of naphthalene. The amount of sulphuric acid to be used, will vary with the degree of nitration desired, and it ranges from 4:1 (nitric:sulphuric) for low melting points, to 3:2 for the higher derivatives.—D. B.

*Gunpowders, Composition of Various.* Merle. *Moniteur Scientif.* 1897, 25; through *Pharm. Centralh.* 1897, 38, [31], 503.

ACCORDING to the author, the following is the composition of certain powders:—*Diorcerin*: Potassium nitrate, 42.78; sodium nitrate, 23.16; sulphur, 13.40; charcoal, 7.49; wood powder, 10.97; picric acid, 1.65; moisture, 0.55 parts. *Azotin* and *Halorglin* also contain sodium nitrate, which, weight for weight, gives more oxygen than the potassium salt. *Amid.* contains 38 per cent. of ammonium nitrate; it gives but little flame, but develops great power. *Saxifragin* contains barium instead of potassium nitrate; its energy is, however, but slight.

Among the blasting powders which derive a part of their oxygen from potassium chlorate, are:—*Hinly Powder*, containing potassium chlorate, 45; potassium nitrate, 35; coal tar, 20 parts. The tar is dissolved in benzene, mixed with the salts, and the solvent driven off. *Michalewsky Powder* contains potassium chlorate, 50; manganese peroxide, 5; and bran, 45 parts. *American Comet Powder* consists of a mixture of potassium chlorate, 75; resin, 25 parts. *Augendre Powder* contains potassium chlorate, 49; sugar, 23; potassium ferrocyanide, 18 parts. *Janile* contains potassium nitrate, 70; sulphur, 12; bitumen, 18; picric acid, 0.4; potassium chlorate, 0.4; sodium carbonate, 0.3. *Amidogen* consists of nitre, 73; sulphur, 10; charcoal, 8; starch or bran, 8; and magnesium sulphate, 1. *Lithofracteur* contains sodium nitrate, 65; sulphur, 13; and gun-cotton, 22 parts.—J. O. B.

*High Explosives, The Walker Method of Firing.* J. Mein. *Eng. and Mining J.* 1897, 64, [13], 364.

THE object of this method is to avoid the danger incident to the ramming of shots when the detonator and charge of high explosives are placed together in the shot-hole. A paper tube, 6 in. in length and  $\frac{1}{2}$  in. in diameter, is fixed in the charge, preferably during the process of manufacture. This tube forms a chamber for the reception of the detonator. The charge is placed in position in the shot-hole by means of a hollow brass or copper tube, of sufficient length to suit any hole, with an outside diameter of  $\frac{1}{2}$  in. and an internal diameter of  $\frac{3}{8}$  in., and with one end slightly reduced in thickness, so as to admit of its being inserted into the paper tube. Then, after the ramming is finished, the detonator is pushed through the hollow tube by means of a copper rod. The detonator being held in position by means of a simple spring made of cane or some similar material, the copper rod and hollow tube may be simultaneously withdrawn, and the shot fired in the usual way. The total additional cost of this arrangement is said not to exceed 1 c. per shot.—A. S.

*Phosphates, Alkalim Earth [NPhO<sub>3</sub>]; Manufacture and Properties of.* G. Kassner. *Rev. Chim. Ind.* 1897, 8, 227.

See under VII., page 913.

## PATENTS.

*Mixing and Conveying Acids for Use in Nitroglycerine and other Manufactures. An Improved Method and Apparatus for.* G. Kynoch and Co., Ltd., and A. T. Cockings, Witton. *Eng. Pat.* 22,717, Oct. 13, 1896.

DRAWINGS and descriptions are given of the apparatus employed, which consists of two vertical closed iron cylindrical vessels, supported over a larger horizontal cylinder, with which they are connected by pipes and cocks. The vertical vessels contain the nitric acid and the sulphuric acid, and serve as measuring vessels, and can be put in connection with a vacuum pump; and the invention consists in "introducing the acids into their respective measuring vessels by means of reduced pressure therein," and, after allowing the acids to flow into the lower vessel, mixing and delivering them by means of compressed air.—W. M.

*Nitroglycerin Explosives, Impts. in Manufacture of.* C. E. Bichel, Hamburg. *Eng. Pat.* 17,367, Aug. 5, 1897.

This invention relates to the class of explosives in which nitroglycerin is absorbed in a suitable mixture of wood meal and saltpetre, and consists in the replacing of about 5 per cent. of the nitre by "chromates, bichromates, or permanganates of the alkalis."—W. M.

*Matches. Impt. in Manufacture of.* J. Craveri, Buenos Ayres. *Eng. Pat.* 18,563, Aug. 10, 1897.

THE inventor proposes a composition for the heads of matches or tapers, which is entirely free from phosphorus.

The following proportions are given:—

"Acid persulpho-cyanic, 2 parts; cyanogen persulphide, 4 parts; nitronaphthalene, 2 parts; xanthate of potassium, 1 part; charcoal, 1 part; chlorate of potassium, 20 parts; peroxide of lead, 50 parts; trisulphide of antimony, 10 parts; gelatin or fine glue, 10 parts."—W. M.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*Sulphur, Determinations in Iron and Steel, A New Apparatus for, and a Useful Form of Wash Bottle.* R. K. Meade. *J. Amer. Chem. Soc.* 1897, 19, 581—585.

THE apparatus shown in Fig. 1, and drawn to one-eighth scale, consists of the following parts:—(1.) A 500 c.c. flask of the "Joliet" pattern, fitted with an india-rubber stopper

Fig. 1.

having two holes, through one of which passes a funnel with glass stop-cock, and through the other a piece of glass tubing bent at right angles about the middle point. (2.) A

1-oz. separating funnel fitted with a two-hole rubber stopper provided with tubes for the admission and exit of the gases. The tube leading from flask to funnel is blown into a bulb of 25 to 50 c.c. capacity. The funnel itself is indented in three places, equi-distant from each other, and about  $\frac{1}{2}$  in. from the bottom, or just where the walls begin to narrow to meet the stop-cock. In the bottom of the funnel is placed a little glass wool, and upon this sufficient asbestos to reach level with the dents in the walls of the funnel. Over this, a thin perforated disc of platinum, made to fit the funnel closely, is pressed down under the dents, holding the asbestos in place. (3.) A separating funnel fitted similarly to the one described under (2), except that the tube leading into it is not blown into a bulb. (4.) A wooden stand upon which the entire apparatus rests.

The separating funnels are half filled with an alkaline solution of lead nitrate, the sample is weighed into the flask, the apparatus connected together, and dilute acid poured upon the borings. When action moderates, the contents are heated until all gas is given off. A moderately rapid current of hydrogen is passed through the apparatus for a few minutes, after which the flask and funnels are disconnected. The alkaline solution is run through a filter and collected in a flask, lead sulphide being retained on the filter. A small quantity of potassium chlorate, together with 20 c.c. of concentrated hydrochloric acid, are introduced into the funnels to dissolve any sulphide which may be mixed with the asbestos. After washing the funnels and filters, the filtrate is heated to boiling, nearly neutralised with ammonia, and the sulphur precipitated with barium chloride. The hydrogen sulphide is in most cases completely absorbed in the first funnel, should any form, however, in the second funnel, this must be collected and dissolved and the solution added to that from the first funnel.

Fig. 2 represents a wash-bottle of the usual type except that the shorter tube is made of very stout glass tubing.

Fig. 2.

To this is fastened a piece of hard wood  $\frac{3}{4}$  by 1 by  $\frac{3}{4}$  ins., notched with a V-shaped notch across its face and with a groove cut down its sides parallel to the neck of the flask. A piece of stout wire is bent with a loop at either end. The larger of these loops is made of sufficient size to admit the thumb comfortably and is covered with a piece of small rubber tubing. The smaller is bent over the rubber tubing and wood and is large enough to slide up

and down freely in the vertical grooves with about half an inch play. The bottle is grasped by the last three fingers of the hand, and the thumb is passed through the loop in the wire, leaving the first finger free to guide the jet. A slight pull from the thumb is sufficient to bring the wire down upon the rubber, pressing the latter into the notch and effectually closing the opening. By doing this before ceasing to blow into the bottle, the fumes of the acid or steam or whatever volatile substance the bottle may contain, are prevented from passing back into the mouth and a steady stream is kept going from the jet for some moments or until the pressure of the thumb is relaxed, without further effort on the part of the operator.—D. B.

*Beetroot Juice, Flask for the Polarisation of.* D. Sidersky. Bull. Assoc. Chim., 1897, 14, 1170—1171.

THE custom of polarising juice clarified with 10 per cent.

of basic lead acetate necessitates calculations which may be easily obviated.

The author has arranged a flask of 100—110 c.c. with a third mark on the elongated neck indicating 122.8 c.c. as given by the proportion  $(5 \times 16.29) : 100 = 100 : 122.8$ .

On filling the flask to the mark 100 with juice, adding basic lead acetate to 110, and completing to 122.8 c.c. with water, and polarising the filtered liquid, the polariscope reading with a 20 cm. tube will be five times the sugar content per 100 c.c. of juice, and multiplication by 0.2 presents no difficulty.

For the analysis of massecoites, 20 grms. in 100 c.c. of water is made up to 122.8 c.c. with basic lead acetate and water. The direct reading gives the sugar per cent. on the massecoite.—L. J. de W.

## PATENT.

*Gas [Oxygen, Carbonic Acid, &c.] Absorbing Apparatus for Ascertaining the Quantity of a Particular Gas in a Gaseous Mixture [Smoke-Gas, &c.]* M. Arndt, Aachen, Germany. Eng. Pat. 25,762, Nov. 16, 1896.

THE apparatus consists of an upper vessel for containing the gas, and a lower vessel for enclosing the absorbing medium, these vessels being connected end to end, but being normally separated by a movable closure or partition which carries or has connected to it, the absorbing medium. Solid absorbents, such as phosphorus rods for oxygen, are enclosed in a cage attached to the partition, whilst in the case of liquid absorbents, such as potash lye for carbonic acid, plates or fragments, &c. of glass, pumice stone, &c. are wetted or saturated with the liquid. The gas vessel is connected through a three-way supply cock to a measuring tube, the open lower end of which is immersed in a vessel of liquid. When the gas vessel has been filled with the gas, the partition and the absorbing medium are raised into the gas vessel until all absorption has taken place, the diminution in volume of the gas being indicated in the measuring-tube. The gas vessel may also be connected with a vacuum gauge, the pointer of which indicates the degree of rarefaction produced by the absorption.—R. A.

## INORGANIC CHEMISTRY.—QUALITATIVE.

*Arsenic, Antimony, and Bismuth: Separation from the Precious Metals by Hypophosphorous Acid.* L. Vanino. Ber. 30, [14], 2001—2003.

PLATINUM, iridium, and rhodium are not precipitated from strongly acid solution by hypophosphorous acid, and can thus be separated from ruthenium, palladium, osmium, gold, silver, mercury, arsenic, antimony, and bismuth, which are so precipitated. If to this precipitate, hydrogen peroxide be added in sufficient quantity, the last three metals redissolve, and can be separated from the rest by filtration, and then reprecipitated by warming after addition of more hypophosphorous acid, when the arsenic falls almost at once, the others after a longer time.—J. T. D.

*Selenium in Commercial Sulphur.* T. D. Reed, M.D. Amer. Pharm. Assoc. 1897; through Pharm. J. 1897, 59, [1421], 264.

THE author finds that there is no difficulty, in America, in obtaining sulphur free from selenium. The official test of the U.S.P. consists in boiling 0.5 gm. of the sulphur with 0.5 gm. of potassium cyanide in 5 c.c. of water and filtering, then adding excess of hydrochloric acid to the filtrate. In the presence of selenium a reddish coloration is obtained. In order to obtain more complete solution of the sulphur, it was found necessary to increase the amount of cyanide to 1.25 grms., and continue the boiling for half an hour. To determine the delicacy of the test, an experiment made with fused selenium showed that it would indicate  $\frac{1}{100}$  of a grain. Care must be taken to avoid traces of iron, since that metal gives a coloration with the test closely resembling that of selenium.—J. O. B.

## INORGANIC CHEMISTRY.— QUANTITATIVE.

*Water-Analysis. Colorimetric Estimation of Ammonia, of Nitrites, and of Iron.* J. König. Chem. Zeit. 21, [60], 599—601.

To avoid the labour of preparing continually fresh solutions for colorimetric comparison, and to provide a uniform set of tints, the author has had copied by a painter the tints produced in 100 c.c. of water containing known quantities of ammonia, of potassium nitrite, and of iron, by Nessler's reagent, zinc iodide and starch, and ammonium sulphocyanide solution respectively. These tints have been reproduced by lithography, and six graded slips, length and breadth corresponding to the height and diameter of a Nesslerising tube filled to the 100 c.c. mark, are arranged as the faces of a hexagonal prism, on a stand, so that they can be rotated round a vertical axis, and successively brought into comparison with a Nessler glass, containing the liquid for examination, which is supported on an arm of the same stand. These slips are marked in each case with the quantity of ammonia (or other substance) in 100 c.c., to which they correspond; but the author advises each analyst to make and test a series of standard solutions, and once for all to mark the corrections that may be needed for his personality. This done, the estimation of ammonia in a water is made by taking 300 c.c. of the water, adding to it in a stoppered cylinder, 2 c.c. of sodium carbonate solution (2.7 pure soda crystal in 5 parts of water) and 1 c.c. of caustic soda (1 part pure sodium hydroxide in 2 parts of water), shaking, allowing to settle, and pouring off 100 c.c. into the Nessler cylinder. If, after addition of the reagent, the colour be deeper than the deepest tint, 50 c.c. are poured away and 50 c.c. of pure water added. When the right tint has been struck, check experiments may be made by diluting to different extents successive quantities of the water, but this dilution must not be carried too far. For the estimation of nitrites, 100 c.c. of the water can be used directly, save in the case of muddy or coloured waters, when precipitation by sodium carbonate, sodium hydroxide, and a little alum is resorted to, exactly as in the case of ammonia. To 100 c.c. of the water, zinc iodide and starch are added and a little dilute sulphuric acid, and the tint struck compared with those on the appropriate comparison instrument. For iron, 200—500 c.c. are oxidised by boiling with a fragment of potassium chlorate and 1 c.c. of hydrochloric acid, allowed to cool, brought to the original bulk with distilled water, and 100 c.c. taken for the estimation.—J. T. D.

*Total Ammonia in Gas Liquor, Estimation of.* E. Donath and K. Pollak. Zeits. angew. Chem. 1897, 555.

By direct experiment the authors find that sodium hypobromite decomposes thiocyanogen, producing a certain amount of gas which contains carbonic oxide as well as nitrogen. The processes for estimating the ammonia in gas liquor, which depend on the measurement of the nitrogen evolved by the action of this reagent on the ammoniacal salts, are therefore not trustworthy, as they cause the samples to be valued above their true strength; and it is accordingly necessary to fall back upon the older methods of distillation with lime.—F. H. L.

*Iron, A Modification of the Permanganate Method for the Determination of.* H. P. Cady and A. P. Ruediger. J. Amer. Chem. Soc. 1897, 19, 575—581.

The authors have found it possible to titrate iron with permanganate in the presence of hydrochloric acid, by adding an excess of mercury sulphate to the solution. The solutions are prepared in the following manner:—

*Solution A.*—A 5 per cent. solution of stannous chloride. This need not necessarily be freshly prepared, but it should give no precipitate when diluted with 20 times its volume of water and boiled. It may be kept in good condition by acidifying with hydrochloric acid and putting a few fragments of tin into the bottle.

*Solution B.*—Hydrochloric acid of sp. gr. 1.10.

*Solution C.*—This is made by adding to 200 grms. of mercuric sulphate, 80 c.c. of concentrated sulphuric acid, and mixing the resulting paste with 800 c.c. of water. (If

a yellow precipitate be formed, more sulphuric acid is added.) To this is added 100 grms. of orthophosphoric acid dissolved in a small quantity of water, and the whole is made up to one litre.

*Method 1.*—Dissolve the substance in water with a varying quantity of hydrochloric acid, and heat to boiling after diluting to 100 c.c., reducing with stannous chloride until the solution becomes colourless, and potassium thiocyanate (sulphocyanide) ceases to give a coloration. Any excess of stannous chloride that may have been used is oxidised by potassium permanganate until the solution gives a faint but distinct colour with potassium thiocyanate, after which, one or two drops of stannous chloride are added very cautiously. This operation is carried on at a boiling heat. After cooling the solution, 50 c.c. of dilute sulphuric acid are added, and for every 10 c.c. of hydrochloric acid that has been used, 35 c.c. of the mercury sulphate solution; the whole is then diluted to 400 c.c., and titrated with potassium permanganate.

*Method 2.*—The substance is dissolved best in a small Erlenmeyer flask in 15 c.c. of hydrochloric acid, 2 c.c. of mercury sulphate are added, the mixture is heated, and stannous chloride added in small quantities at a time, until the solution becomes colourless. The contents of the flask are rinsed into a beaker and diluted to about 300 c.c., 50 c.c. of dilute sulphuric acid are added, and then 45 c.c. of mercury sulphate. The solution is then ready for titration without cooling, as the amount added should cool it sufficiently. Method 1 can be used in all cases, while method 2 (which is much shorter), can always be used where there is not too much insoluble residue, which might obscure the end of the reaction. The points requiring special care in this process are:—

1. Use stannous chloride which is in good condition.
2. Have the smallest possible excess of stannous chloride present after the reduction is completed.
3. Carefully adjust the proportions between the mercury sulphate and the hydrochloric acid. Less than three minutes, in the case of soluble salts, has been found sufficient time for solution, reduction, and titration.—D. B.

*Iron and Aluminium, The Separation of, by means of Sodium Peroxide.* C. Glaser. Chem. Zeit. 1897, 21, 678.

Ferric oxide and alumina, in phosphates and other minerals, may be separated and estimated quantitatively by making use of their different behaviour towards sodium peroxide; for, while solutions containing aluminium are affected by this reagent exactly as by alkalis or alkaline carbonates, this is not the case with ferric salts. When a solution of a ferric salt is treated in the cold with excess of dry sodium peroxide, no precipitate is formed in the effervescing liquid, and any cloudiness observed disappears on adding excess of reagent. The iron is present as a ferrate, and on boiling is precipitated as hydroxide; and for quantitative estimation this precipitate should be dissolved in hydrochloric acid, and the iron reprecipitated with nitroso- $\beta$ -naphthol or with ammonium sulphide, the latter in ammoniacal solution containing citric or tartaric acid. The precipitate is, in either case, converted into ferric oxide and weighed in this form.

A solution containing iron and aluminium in the absence of calcium phosphate is nearly neutralised with ammonia, and is then ready for the separation; if, however, calcium phosphate be present, it must be carefully removed by means of ammonium acetate or by E. Glaser's method, and the solution then nearly neutralised as before. To the cold solution, dry sodium peroxide is added until the solution appears perfectly clear. As a rule for 0.4 gm. of substance there is required 3—6 grms. of sodium peroxide. The clear solution is rapidly heated to boiling point, the precipitate allowed to settle, and the whole poured through a thick filter. In the filtrate, alumina is estimated by a usual method, preferably by precipitation with pure phosphoric acid in the presence of ammonium acetate. The ferric hydroxide is dissolved in hydrochloric acid and purified as described above. In the presence of silicates the results may be slightly too high, and the original solution should therefore be free from silicic acid.

The author considers the above separation more rapid than the ordinary fusion method, and free from the disadvantage of the latter that the platinum crucible employed is slightly attacked, and the apparent weight of the ferric oxide increased by traces of platinum.—R. B. B.

*Zinc, Estimation of, by the Schaffner Method in Plumbiferous Minerals.* H. Pellet. Bull. Assoc. Belge des Chim. 11, [4], 126—130.

HAVING found that the ammoniacal salts, produced when ammonia is employed to neutralise the acid solution of the mineral before titrating the zinc with sodium sulphide, retain in solution the lead present, and so falsify the titration, the author substitutes potash in that operation, leaving the liquid just sufficiently acid to prevent the deposition of the zinc. The solution is then poured into ammonia, agitated, and filtered, the filtrate being titrated with standardised sodium sulphide, one drop of ferric chloride (20 per cent.) solution being added as indicator. By this means the method retains its accuracy even in presence of 40 per cent. of lead, whereas in the ferrocyanide method the lead has to be removed before titrating the zinc.

It is found that the volume of sodium sulphide solution required per unit of zinc increases slightly with the dilution of the liquid.

An important point is to pour the neutralised solution into the ammonia, and thereby obviate the deposition of zinc oxide, which would otherwise have to be redissolved.

In dissolving the mineral, the author prefers to oxidise the iron present by means of potassium chlorate instead of nitric acid.—C. S.

*Nickel and Cobalt. Separation from Iron.* O. Duern. Comptes Rend. 1897, 125, [11], 436—439.

If a solution of iron containing nickel be precipitated by excess of ammonia, part of the nickel dissolves, part goes into the precipitate. But if the solution with the precipitate suspended in it be now electrolysed, the whole of the nickel is deposited on the cathode, along with a trace of iron, which, in exact analyses, can be subsequently determined. In the process of analysis, the solution, in which the iron has been peroxidised, is evaporated to dryness with a slight excess of sulphuric acid, taken up with as little water as possible, 5 to 10 grms. of ammonium sulphate added, and the whole warmed till a clear solution is obtained. The liquid is transferred to Riche's apparatus (Ann. Chim. Phys. [5], 13, 528), in which has been placed 60 or 70 c.c. of strong ammonia, and electrolysed with a current density of 25 to 45 milli-amperes per sq. cm. of the cathode. In less than four hours the electrolysis is complete. Figures are given both for known mixtures of iron and nickel or iron and cobalt and for nickel steels, which show that the method is very accurate, and that for ordinary purposes it is not necessary to take into account the iron deposited on the cathode. Silicon and carbon need not be separated in the first place, nor do the small quantities of manganese or phosphorus, or of chromium, interfere with the method. A small amount of chromic acid, however, prevents the deposition of the nickel; the author has this point under investigation.—J. T. D.

*Nickel-Copper Alloys, Assay of.* A. Riche. J. Pharm. Chim. 1897, 6, [7], 300—303.

THE minting of cupro-nickel with 15 or 25 per cent. of nickel has necessitated the introduction of a safe and rapid method of assay. It is only needful to determine one constituent of a binary alloy, and in this case, owing to the higher price and lower purity of nickel, this metal may be estimated, and the copper may be found by difference. Formerly the author had precipitated the copper electrolytically with an element giving an E.M.F. of 2 volts, and had deposited the residual nickel in ammoniacal solution with two such elements. Under these conditions the nickel solution rapidly grows warm, and the deposit may become grey, loose, and even partly oxidised. It is better therefore to use only 3 Daniell cells—a method which gives perfect results and demands no supervision. From 0.5 to 1 grm. or more of alloy is dissolved in the minimum of nitric acid, a little water is added after solution is complete,

and the nitric acid is expelled by two consecutive evaporations with 5–6 drops of sulphuric acid. After redissolving in water with a few drops of sulphuric acid, the copper is deposited electrolytically until the solution gives no indication with bicarbonate and ferrocyanide. The cone with the copper is then washed into the containing vessel, and may be weighed. The residual solution is then mixed with an excess (usually 12–15 c.c. suffices) of ammonia, and is electrolysed with 3 Daniell cells. The results are quite concordant, but the analysis may show a deficiency of 0.8–0.9 per cent., due to impurities in the nickel, some of which are observable, forming a reddish flocculent precipitate in the solution, which, however, does not interfere with the accuracy of the nickel determination. It was formerly believed that a current with an E.M.F. lower than 2 volts would fail to deposit nickel from ammoniacal solution. By allowing a longer time (a whole night), the deposition may be effected completely with a current of 0.1 ampère from the battery employed for the copper electrolysis. The cone with the nickel deposit is washed successively with water and alcohol, and is dried and weighed. In the assay of coinage alloys, 0.175 grm. of good copper is deposited in 4 hours with a current which falls during that time from 0.5 to 0.1 ampère. The nickel is deposited in 4 or 5 hours, the ampère meter showing a current of 0.3 ampère at the beginning, and 0.1 to 0.2 at the end of the operation, when 15 c.c. of ammonia has been used.—W. G. M.

# ORGANIC CHEMISTRY.—QUALITATIVE.

*Dégrads, Genuine and Artificial; Distinction between.* F. Jean. Rev. Chim. Ind. 1897, 8, 227. (See also this Journal, 1895, 281; 1896, 937; 1897, 639; 1891, 557.)

IN a note appended to Baron's paper on artificial dégrad (see page 922), the author states that on salting out the sodium soaps of true moëillon, and decomposing them with hydrochloric acid, a black, brittle, resin-like body called *dégradène* is produced, which contains nitrogen, and is soluble in alcohol and ether, but insoluble in petroleum spirit. Artificial dégrad also yields a similar compound analogous to leucine, but it is accompanied by a large proportion of another substance of like appearance, which is free from nitrogen.—F. H. L.

*Earthnut, Detection of, in Chocolate.* Bilteryst. Bull. de l'Assoc. belge des Chim., March 1897, 447; through J. Pharm. Chim. 1897, 6, [1], 29.

TO DETECT the addition of arachis by microscopical examination, the chocolate is first freed from fat and sugar, and then examined in a medium of water and glycerin. The characteristic starch granules of arachis are thus shown very distinctly; they are larger than those of the natural starch of theobroma and each granule has a central nucleus.

The powder free from fat and sugar, is also macerated for 24 hours in a solution of 50 grms. of chloral hydrate in 40 grms. of water. The characteristic cells of *Arachis hypogaea* are then easily distinguished by their peculiar internal markings. Chemically, the adulteration is detected by the examination of the separated fat and the determination of the albuminoids. The fat is extracted by means of carbon tetrachloride, and its refractive index determined with the oleorefractometer. The figure for pure cacao butter is  $-19^{\circ}$ , while for earthnut fat it is  $+3^{\circ}$ . The author found the refraction index of the fat of a mixture of 5 per cent. of arachis with chocolate to be  $-18^{\circ}$ , and of that from a 50 per cent. mixture  $-7^{\circ}$ . This method, however, alone, will not reveal the presence of pressed mare of earthnut in chocolate. To detect this latter adulteration the determination of the albuminoids must be made. Cacao contains 18 per cent. of these; arachis, 20 per cent.; and the oil-free mare of earthnut, 45 to 47 per cent. of albuminoids.

—J. O. B.

*Eucalyptol [Tests for Purity of].* A. Schamelhout. Ann. Pharm. 1897, 3, 257.

A USEFUL reagent for the detection in eucalyptol of small amounts of eucalyptol oil and turpentine, consists

of a solution of 10 drops of bromine in 10 c.c. of pure chloroform. This reagent also serves to detect turpentine in eucalyptus oil. The reagent is added drop by drop. A yellowish-green colour is first produced, which changes on further addition to reddish yellow; and the number of drops necessary to bring about these colour changes indicates the purity of the sample. For example:—

	Drops of Reagent	
	For Yellowish-Green Colour.	For Reddish-Yellow Colour.
Pure eucalyptol .....	4	8
Rectified oil of turpentine .....	No coloration, even with 250 drops.	
Eucalyptus oil .....	25	95
Eucalyptol, with 5 per cent. eucalyptus oil ..	11	18
Eucalyptol, with 2.5 per cent. eucalyptus oil ..	7	12
Eucalyptol, with 2.5 per cent. turpentine ..	16	23
Eucalyptus oil, with 2.5 per cent. turpentine ..	..	135

— R. B. B.

*Bisabol Myrrh, Composition of, and Distinction from Official Myrrh.* Tscholka. Arch. der Pharm. 1897, 290; through Pharm. Centrallh. 1897, 38, [31], 500.

Six drops of a 1 in 15 petroleum ether extract of bisabol myrrh are mixed with 6 c.c. of acetic acid; then 3 c.c. of concentrated sulphuric acid are added, so as to form a lower layer. A rose-red colour is developed at the line of contact, and in a short time the whole acetic acid solution is coloured red, the tint being permanent for some time. If the petroleum extract be made stronger than 1 in 15, a brown colour is produced. Official myrrh treated in a similar manner gives only a slight red colour in the acetic layer, which does not intensify on standing; and the zone of contact is at first green, then brown, with a greenish fluorescence. Bisabol myrrh contains: gum soluble in water, 22.1; gum soluble in soda solution, 29.85; resin, 21.5; bitter principle, 1.5; volatile oil, 7.8; water, 3.17; vegetable and inorganic matter, 13.4 per cent.

The essential oil gave the above characteristic colour reaction very markedly; when treated with gaseous hydrochloric acid by Wallach's method, the terpene gave small, well-formed crystalline tablets of hydrochloride melting at 79.3° C. The terpene itself, which is named bisabolene, had the abnormally high boiling point 259—260.3° C., and has not been identified with any similar body hitherto isolated. It is considered probable that it consists of a double molecule ( $C_{10}H_{16}$ )<sub>2</sub>. Besides bisabolene the oil probably contains alcoholic bodies and esters, since it reacted violently with benzoyl chloride on warming. The reddish-brown oil from which the crystalline bisabolene hydrochloride had been separated, fractionated between 230—231° C., also gave the characteristic colour reaction. The resin soluble in alcohol was markedly acid in reaction; it contained two acids, giving soluble and insoluble lead salts respectively. The gum soluble in water is probably a calcium arabinat.—J. O. B.

#### ORGANIC CHEMISTRY.—QUANTITATIVE.

*Hæmatoïn, The Estimation of, in Logwood Extracts.* Aglot. With Report by E. Jaquet and O. Michel. Bull. Soc. Ind. Mulhouse, 1897, 250—258.

A solution of the sample of a definite strength is prepared, a few drops of ammonia added, until a cherry-red colour just appears, and normal potassium chromate then added in sufficient amount to change the colour to a blue-free from violet. By means of the author's optical apparatus a definite source of light is viewed through a layer of the liquid thus produced, and the thickness of the layer is adjusted until no light reaches the eye. The amount of colouring matter is inversely proportional to the thickness of the layer when absorption of light is complete. For the above test, 10 grms. of the sample are

dissolved in a litre of water, 10 c.c. of this solution are made alkaline with ammonia, and 10 c.c. of a 3 per cent solution of potassium chromate added; the liquid is then boiled for 10 minutes, allowed to cool, and diluted to 50 c.c. A part of this solution is introduced into the apparatus and observed as described. According to the author's results, the presence of impurities, such as chestnut extract or molasses, does not cause a difference of 1 per cent. in the amount of colouring matter found, and he therefore concludes that this method may be used for the comparison of samples from various sources with each other and with pure hæmatoxylin.

When testing different samples from the same factory, where approximately the same wood is always used and chestnut extract is not added, it suffices to precipitate portions of the solution with albumin and with acetate of iron, the former causing precipitation of tannin only, the latter of tannin, certain pectic matters, and hæmatoïn. The wood will always contain tannin and hæmatoïn in the same relative proportion, and the total effect of the iron varies directly as the hæmatoïn, and is estimated by means of the optical apparatus used in the former case.

In order to detect the presence of chestnut extract in a sample of logwood extract, the following tests are made:—(1) On the addition of tartar emetic pure logwood extract is not precipitated, but chestnut extract produces a gelatinous deposit. (2) With pure extract, acid nitrate of bismuth gives a cloudiness which redissolves in excess of the reagent, and a deposit is only formed on prolonged standing; but if any tannin extract be present, the cloudiness does not disappear, and a deposit is formed in 10 minutes.

*Report.*—According to E. Jaquet and O. Michel, the author's methods are only suitable for approximate determination of the amount of hæmatoïn, or for detection of a considerable quantity of chestnut extract. They consider that the amount of colouring matter can only be estimated to within 2—3 per cent., and the method in their opinion is ingenious but not exact, though possibly capable of being brought to greater perfection.—R. B. B.

*Indigo, Assay of.* A. Brylinski. Bull. Soc. Ind. Mulhouse, 1897, 331—345. (See also this Journal, 1897, 701—702.)

Indigo may be estimated—(1) gravimetrically; (2) by oxidation; (3) by reduction; (4) colorimetrically; and (5) by comparative dye tests. A typical process for each

of these methods is described, and their relative value discussed. The author concludes the method by reduction, as proposed by G. Engel, to be the best. The process is based on the fact that indigo can be reduced quantitatively by a solution of vanadyl sulphate.

When an acid solution of vanadium sulphate is reduced by zinc, two successive stages of reduction are observable. The originally yellow solution at first turns green, forming vanadous sulphate, which may also be obtained by reducing with a bisulphite. This vanadous sulphate reduces permanganate and ferric salts, but not indigo. On continuing the addition of zinc to the hot solution, the latter turns to a purplish-blue colour; this is the vanadyl sulphate of Würtz, recommended by Engel for the titration of indigo. The solution can, however, be only used in an inert atmosphere, as it absorbs oxygen from the air very rapidly, being reconverted into vanadous sulphate. The titration is performed, therefore, with a special apparatus in the presence of a current of  $\text{CO}_2$ . The vanadyl sulphate solution is run from a burette into a measured solution of indigo carmine until the colour of the latter has disappeared. The solution passes from a green to a pale yellow, the end reaction being indicated by a greenish-grey colour.

The details of the process are as follows:—10 grms. of ammonium vanadate are dissolved in 100 grms. of sulphuric acid of 66° B., with the aid of heat. The resulting red solution is poured into two litres of water of 50° C. To this are added by degrees 50 grms. of zinc powder until the solution shows a purplish-blue colour. Filter and allow to cool.

A measured quantity of indigo solution is put into an Erlenmeyer filtering flask, provided with a side tube. This flask is closed with a double perforated cork, through which two tubes pass, one of them being connected with the burette, and the other with a  $\text{CO}_2$  generator, as shown in the drawing. At first a standard indigo is titrated, and then the sample to be assayed, and the value of the latter is then calculated.

To guard against the possibility of oxygen being carried into the apparatus by the  $\text{CO}_2$ , the latter should be purified by first passing it through a solution of vanadyl sulphate. The small quantities of ferric salts present in the solution may occasion a very slight error, which may in most cases be neglected. But if need be, the iron present may be determined in the ash of a separate portion, and the quantity of vanadyl sulphate used for its reduction determined.

—I. S.

*Sugar Content of Some Tropical Fruits. Determination of.*  
H. C. Prinsen-Geerligs. Chem. Zeit. 1897, 21, 72, 739.

A QUANTITY of the fruit was taken, and the amount of external covering, flesh, and stone determined. 100 grms. of the edible portion were triturated with calcium carbonate to neutralise organic acids or acid salts, and then extracted with alcohol. The neutral alcoholic extract was evaporated on the water-bath, the residue taken up with water, treated with neutral lead acetate, and made up to 100 c.c. with water. After filtration, the solution was polarised and the amount of cupric reducing sugars determined in an aliquot portion. 50 c.c. of the filtrate were inverted with 5 c.c. of hydrochloric acid, and after dilution to 100 c.c., the solution was polarised and the cupric reducing power determined. The difference between the amount of cupric reducing sugar before and after inversion, was considered as due to cane sugar; and the percentage of this sugar was calculated from that value, since in no case was there any evidence of the presence of maltose or other carbohydrates capable of hydrolysis. The specific rotation of the reducing sugars was deduced from the difference between the calculated polarisation corresponding to the amount of cane sugar found as above and that observed in the original solution. Since it was assumed no reducing sugars but dextrose and levulose were present, the amounts of these two could be calculated from the above-mentioned difference. The following table shows the results obtained by the author:—

Fruit from	Average Weight of a Single Fruit.	100 Parts of Fruit contain			100 Parts of Flesh contain		
		Flesh.	Skin.	Stone.	Cane Sugar.	Glucose, Levulose.	Total Sugar.
<i>Achras sapota</i> [sapodilla plum or naseberry].....	60 grms.	85	13	2	7.02	3.70	11.12
<i>Ananassa sativa</i> [pine-apple].....	300 "	67	33	..	8.61	1.93	10.21

—J. L. B.

*Beeswax, The Examination of.* S. Weinurm. Chem. Zeit. 1897, 21, [52], 519—520.

In working Hübl's process the author shortens the saponification by heating the wax and alcoholic potash in a covered flask for 30 minutes on a water-bath, then removing the cover and completely evaporating the alcohol. For the detection of small quantities of paraffin or cerasin, he describes a method based on the fact that an aqueous solution of glycerin dissolves the normal unsaponifiable matter in beeswax, whilst paraffin and cerasin (or 5 per cent. of

resin) are insoluble. 5 grms. of the filtered beeswax are saponified with 25 c.c. of semi-normal alcoholic alkali in the manner described above, and, after the addition of about 20 c.c. of glycerin the flask is heated on the water-bath until there is a clear solution and then for several minutes longer. On now adding 100 c.c. of boiling water, the liquid remains more or less clear and transparent in the case of genuine beeswax, and it should be possible to read printed matter when placed beneath the flask. But when 5 per cent. of cerasin or resin is present, the liquid is turbid and it is

no longer possible to read the print through it. When a wax gives normal or nearly normal figures by Hübl's process, and a clear solution is obtained in this way, the sample is either pure or contains not more than about 3 per cent. of cerasin or resin. A second determination is now made, after addition to the wax of 5 per cent. of cerasin (0.25 grm.), and if the solution is only slightly turbid it proves that no cerasin was originally present; if, on the other hand, there is a marked precipitate, about 3 per cent. was present. If the first test gives a turbid solution it points to the presence of about 5 per cent. of either cerasin or resin. 3 per cent. of cerasin is then added to the wax before saponification, and a second test is made. If the original impurity was cerasin, there is now a precipitate; if not, there is still only a turbidity. Since cerasin enters into the composition of nearly all wax substitutes, this method alone is often sufficient to detect adulteration, and when carnauba wax and stearic acid are employed so much of the latter is required that the detection of the admixture is easy. The author has examined a large number of samples by this method, and in some has detected the addition of trifling amounts of cerasin and tallow.—C. A. M.

*Cellulose Carbohydrates, Quantitative Separation of, in Vegetable Substances.* W. Hoffmeister. Landw. Versuchsstat. 1897, 48, 401; through Chem. Zeit. 1897, 21, 198.

THE substance is first extracted with ether to remove all fat; the fat-free residue is then extracted, in the cold, by maceration in successive quantities of dilute hydrochloric acid and ammonia alternately, bodies containing much starch being first treated with malt extract to render that substance soluble. When extracted as far as possible in this manner, the residue, without drying, is treated with a 5 or 6 per cent. solution of soda. It is macerated for 1 or 2 days with occasional shaking, then slightly diluted, allowed to deposit, the clear solution decanted, and the insoluble matter thrown on a filter and washed with hot water. The alkaline extract is neutralised with hydrochloric acid, and the hemicellulose precipitated by pouring into a large excess of alcohol. The precipitate is collected, dried, and weighed. The insoluble residue is then extracted in a similar manner with Schweitzer's reagent and the resulting extract poured into alcohol, as above, to precipitate the cellulose. The residue which remains after this treatment is quite resistant to all solvents, and is dried and weighed as lignin. In each case the final product must be washed with a slight excess of ammonia before drying, to remove any trace of adherent hydrochloric acid, which is difficult to remove by simple washing, and the presence of which, during drying, causes decomposition.

The following are some figures obtained by this method:—

	Hemicellulose.	Cellulose.	Lignin.
Wheat bran.....	17.8 15.54	5.40 4.79	5.10 6.28
Linseed cake.....	2.25 2.4	3.36 3.55	5.61 6.05
Rye bran.....	16.8	2.49	5.94
Rape cake.....	Traces.	2.87	8.62
Hemp cake.....	2.52	1.55	26.28
Sunflower seed kernels..	Traces.	1.45	0.70

—J. O. B.

*Peppermint Oil, Determination of Menthol in.* C. Kleber. Pharm. Rev. 1897, 15, 135; through Chem. Zeit. 1897, 21, 198.

5 GRAMS. of the oil are mixed with 5 grms. of acetic anhydride and boiled for 30 minutes in a flask under a reflux condenser. In the meantime, the same volume of the same acetic anhydride is titrated with normal soda solution, and phenolphthalein. When the boiled fluid has cooled, the reflux tube is washed with a little water, and this is added to the acetylated mixture, and titrated also with normal soda. The difference in c.c. between the two titrations, multiplied by 0.136, gives the amount of menthol contained in the oil.

By this process it only takes about 50 minutes to complete the determination.—J. O. B.

*Balsams, Resins, and Gum Resins; Rational Examination of.* K. Dieterich. Chem. Rev. Fett- u. Harz-Ind. 4, [17], 233--236. (This Journal, 1897, 829--830.)

RESINS (continued). Dammar. Acid number: 1 grm. treated with 50 c.c. of petroleum spirit (sp. gr. 0.7) and left for 24 hours in presence of 20 c.c. of  $\frac{1}{2}$ N aqueous-alcoholic potash. Then titrated (without addition of water) with  $\frac{1}{2}$ N sulphuric acid, and phenolphthalein as indicator. Ash: 1 grm. incinerated and calcined till constant; weighed when cold.

Dragon's Blood.—Resin number: 1 grm. is treated with 50 c.c. of petroleum spirit and acted on for 24 hours by 25 c.c. of  $\frac{1}{2}$ N aqueous potash; then mixed with 250 c.c. of water and 100 c.c. of alcohol and titrated with  $\frac{1}{2}$ N  $\text{H}_2\text{SO}_4$ . Saponification value: Same procedure, except that  $\frac{1}{2}$ N alcoholic potash is employed for the first reaction, the aqueous potash being then allowed to act during a second 24 hours. Dracodilum test: 10 grms. powdered and extracted with 25 c.c. of hot ether, the extract concentrated to 30 c.c., and mixed with 50 c.c. of absolute alcohol. After an hour's rest a white flocculent precipitate comes down. (Characteristic of Palm-dragon's blood only). No free acid is present.

Resina Guaiaci.—Acid number: 20 c.c.  $\frac{1}{2}$ N aqueous-alcoholic potash allowed to react on 1 grm. for 24 hours, followed by addition of 500 c.c. of water and titration with  $\frac{1}{2}$ N  $\text{H}_2\text{SO}_4$ . Ash: Same as for dammar.

Mastic.—Acid number: Same method as for dammar, but with addition of 500 c.c. of water before titration. Ash: Same as for dammar.

Sandarac.—Acid number and ash are determined in same manner as for dammar.

Resina Pini.—Acid number: 1 grm. is dissolved in 50 c.c. of alcohol and titrated with  $\frac{1}{2}$ N alcoholic potash and phenolphthalein until a red coloration ensues. Saponification value: 1 grm. heated with 30 c.c.  $\frac{1}{2}$ N alcoholic potash for an hour under a reflux condenser. Titrated with  $\frac{1}{2}$ N  $\text{H}_2\text{SO}_4$ , after cooling and adding 100 c.c. of alcohol. Ester number: By subtraction.

Storax.—Acid number: 1 grm. dissolved in 200 c.c. of alcohol and titrated with  $\frac{1}{2}$ N alcoholic potash. Saponification value: Same method as for R. pini. Ester number: By subtraction. Loss at 100° C.: 1 grm. dried at 100° C. till constant. Alcoholic portion: 10 grms. dissolved by warming in 100 c.c. of 90 per cent. alcohol, filtered, and washed with 50 c.c. of hot alcohol, the filtrate being evaporated and the residue dried at 100° C. Creeping over is prevented by floating the evaporating dish in a basin of hot water on the water- or steam-bath. The content of dirt and woody fragments is determined by weighing the dried beaker and filter.

Terebinthina Communis et Veneta.—Acid number, ester number, and saponification value: Same methods as for R. pini; no water should be added in the last-named determination.

Gum Resins. Ammoniacum.—Acid number: 0.5 grm. is treated with water, and a current of hot steam passed through the liquid, the flask being heated to prevent condensation. The receiver contains 40 c.c. of  $\frac{1}{2}$ N aqueous potash, which, after 50 c.c. of distillate have been collected and the still neck and tube rinsed out, is titrated back. Resin and saponification values: Two 1 grm. samples are treated with 50 c.c. of petroleum spirit and exposed to the action of 25 c.c. of  $\frac{1}{2}$ N alcoholic potash for 24 hours, with frequent shakings. The one sample mixed with 500 c.c. of water and titrated with  $\frac{1}{2}$ N sulphuric acid gives the resin number, whilst the other, after a further 21 hours' exposure to the action of 25 c.c. of  $\frac{1}{2}$ N aqueous potash, plus 75 c.c. of water, is diluted with 500 c.c. of water and titrated, the saponification value being thus ascertained. Loss at 100° C. is determined by drying. Examination for Galbanum: 5 grms. are boiled a quarter of an hour with 15 grms. of  $\text{HCl}$  (sp. gr. 1.19) and filtered through a wet double filter. On super-saturating the clear filtrate with ammonia, the characteristic blue fluorescence appears when galbanum is present.

*Asafetida*.—*Acid number*: Same method as for R. guniaci. *Saponification value*: 1 grm. of finely-ground average sample is treated as in the case of the last-named resin, except that 200 c.c. of alcohol are added previous to titration. *Ester number*: By difference.

*Gulbanum*.—*Acid number*: Same treatment as for ammoniacum, except that 500 c.c. of distillate are collected in place of 50 c.c. *Resin and saponification values*, also determined as in the case of ammoniacum. *Ash and loss at 100° C.*: Determined by incineration and drying respectively.

*Olbanum*.—*Acid number*: Same method as for mastic. *Saponification value*: 1 grm. of finely-ground sample boiled for one hour with 20 c.c. of  $\frac{1}{2}$ N alcoholic potash under a reflux condenser, and titrated with  $\frac{1}{2}$ N  $\text{H}_2\text{SO}_4$  after adding 500 c.c. of water. *Ester number and ash*: Same as in other cases.—C. S.

*Methyl Alcohol, Formaldehyde, Formic Acid*: *Determination of Small Quantities of*. Nieloux. Bull. Soc. Chim., 1897, 17, 839—840.

THE author's method (this Journal, 1897, 173) for determining small amounts of alcohol, can be applied to methyl alcohol, formaldehyde, or formic acid, provided there be no other substance present in each case capable of reducing bichromate. The procedure is the same as for ethyl alcohol, 5 c.c. of pure concentrated sulphuric acid being added to 5 c.c. of the solution, which is then heated for one minute and allowed to stand for five minutes. The author suggests solutions of bichromate of 19 grms. in the litre (2 c.c. of this solution correspond to 5 c.c. of a solution containing 1 c.c. of alcohol per litre), 17 grms. in the litre (2 c.c. = 5 c.c. of aldehyde of a strength of 1 grm. per litre), and 11 grms. in the litre (1 c.c. = 5 c.c. of formic acid of a strength of 1 grm. per litre) respectively. It is advisable to work with a series of comparison tubes prepared from solutions of known strengths, the better to hit the exact tints.—J. T. D.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Active Oxygen. The Process of Formation of*. W. P. Jorissen. Ber. 30, [14], 1951—1953.

ENGLER and Wild (Ber. 30, 1669) explain the fact that in cases of oxidation by active oxygen, the amounts of oxygen absorbed by the directly-oxidised body (A) and the body oxidised by the active oxygen (B) are equal, by supposing that a peroxide of (A) is formed from the oxygen molecule, and that this peroxide then oxidises B:—

in opposition to van't Hoff's view that the oxygen molecule splits up into electrically opposite atoms, which then effect the oxidation:—

Where such peroxides as Engler and Wild assume can be isolated, and there is nothing in the conditions of the experiment to prevent their formation, the first view is perhaps correct; but such a peroxide may possibly be formed as a result of a previous splitting up of the oxygen molecule:—

Arguments as to the possibility of forming such bodies must not be based on the behaviour of ozone, which is a different thing from active oxygen. In a case just investigated by the author, in which oxygen, rendered active by sodium sulphite, oxidises sodium arsenite, the formation from sodium sulphite of a body functioning like a peroxide would seem to be out of the question.—J. T. D.

*Silicon Carbide*. L. Franck. Stahl und Eisen, 17, 485.

A SAMPLE of cast-iron, in the reduction of which calcium carbide had been employed, was found to contain a noteworthy amount of silicon carbide. The iron was dissolved

by Moissan's method, silicates destroyed by hydrofluoric acid, graphite removed, and the residue treated with aqua regia, hydrofluoric acid, and concentrated sulphuric acid. There remained microscopic well-formed octohedra, partly bluish, partly yellow or greenish, resembling diamond dust. They had a sp. gr. of 3.45–3.3, scratched rubies, and differed from diamond in their action on polarised light. Analysis gave Si 14.34, C 84.95. Further research has shown that this diamond-like silicon carbide is contained in calcium carbide itself, in greater or less quantity according to the amount of silicious impurity in the materials from which the calcium carbide is prepared.—J. T. D.

*Corrosive Mine Waters*. L. J. W. Jones. Eng. and Mining J., 1897, 64, [13], 368.

THE corrosive action of the water of the Stanley Mine at Idaho Springs is so great that ordinary iron pipe is not able long to resist it; indeed, when the exhaust steam of the pumps is discharged into the "sump," the piping will sometimes only last a week. The corrosive action is lessened by the use of compressed air instead of steam. A sample of the water contained a considerable amount of a muddy-brown precipitate, which consisted essentially of hydrated basic sulphate of iron. The filtered water contained 0.3 per cent. of salts, mainly metallic sulphates, in solution. Analysis of the filtered water resulted as follows:  $\text{SiO}_2$ , 0.0438 parts per thousand;  $\text{NaCl}$ , 0.01315;  $\text{Na}_2\text{SO}_4$ , 0.32172;  $\text{K}_2\text{SO}_4$ , 0.15548;  $\text{Al}_2(\text{SO}_4)_3$ , 0.019787;  $\text{ZnSO}_4$ , 0.12244;  $\text{MnSO}_4$ , 0.12714;  $\text{MgSO}_4$ , 0.46716;  $\text{CaSO}_4$ , 0.63629;  $\text{Fe}_2(\text{SO}_4)_3$ , 0.60336;  $\text{FeSO}_4$ , 0.009337;  $\text{CuSO}_4$ , 0.191801; total, 3.002065 parts per thousand. After trying various materials, bronze piping was found to satisfactorily withstand the action of the water. In the discussion on the paper, E. B. Kirby and P. Argall advocated the use of ordinary iron pipes, lined with pine staves,  $\frac{1}{2}$  in. thick. E. Le Neve Foster said that the action of corrosive mine water is greater on wrought-iron than on cast-iron, and that the action is greater, the higher the pressure.—A. S.

*Passive Iron*. J. S. de Benneville. Iron and Steel Institute, Autumn Meeting, 1897.

AFTER a lengthy historical account of the researches on this subject and a discussion of them, the author mentions the following theories of explanation:—(1.) The oxide theory of Faraday and Schönbein. This is the most important, but the objections to it are action by shock, complete solution on activity, and hence failure to prove the insolubility of the oxide, and recovered activity on long standing in copper sulphate. (2.) The insoluble nitrate theory advanced by Braconnot. (3.) Gaseous theory of Mousson and Varenne. This does not explain the activity brought about by solutions of greater strength than those which maintain passivity. (4.) Tomlinson's mechanical theory, against which can be advanced Cailletet's experiments on the effect of diminishing pressure, also the action of strong nitric acid on heating, the passivity induced by contact, the effect of dilution of silver nitrate solutions, the activity induced by shock, and the effect of position in the circuit on passivity. (5.) The magnetic or electrical state theory of Wetzlar and Herschel, which does not conflict with the existence of allotropic iron. (6.) The "altered" or allotropic condition of the iron proposed by Keir and by Senderens.

The passive state being due to an allotropic change in the iron is based on the reaction with copper sulphate solution, and on the instability of the conditions brought about by chemical treatment of the iron. In the present paper an attempt is made to show that previous heat or mechanical treatment has not affected this reaction in the case of mild steel.  $\beta$  and  $\gamma$  iron do not influence, nor can they be identified with iron "altered" by treatment with strong nitric acid. Such change in the iron includes not only allotropic change, but the formation of oxide as shown by the specific gravities and by the volume of hydrogen obtained on solution in dilute sulphuric acid; chemical reactions, however, necessitate the presence of

allotropic iron. Passivity as induced by silver nitrate solutions differs in degree only from that induced by strong nitric acid.—A. W.

*Blast-furnace Slag, Titanium Cyanide Nitride in.* Léon Franck. *Chem. Zeit.* 1897, 21, [52], 520.

Among the substances formed in the glowing interior of a blast-furnace which had been for years uninterrupted at work, the author found well-marked cubes of titanium cyanide nitride. These had a specific gravity of 5.28, were infusible at a high temperature, and insoluble in boiling nitric or sulphuric acid. On ignition in presence of steam, they yielded hydrocyanic acid, ammonia, and hydrogen, and left a residue of titanium oxide. They dissolved in a mixture of nitric and hydrofluoric acids, with the exception of a small amount, which, on treatment with an oxidising mixture, left a residue of about 2.5 mgrms. This residue had a specific gravity of 3.1 to 3.4 (in methylene iodide), was hard enough to scratch the ruby, and when ignited in oxygen left a very minute amount of ash, which, examined micro-chemically, showed all the properties of rutile. Hence the conclusion was arrived at that the specimen of titanium cyanide nitride contained a minute quantity of crystalline carbon with all the properties of the diamond, together with more or less titanium oxide in a different form of combination.—C. A. M.

*Tetraphenyl Methane.* M. Gomberg. *Ber.* 30, [14], 2043—2047.

TRIPHENYLBOMOMETHANE in ethereal solution gives, with phenylhydrazine, an almost quantitative yield of triphenylmethane hydrazobenzene ( $C_6H_5)_3C.NH.NH.C_6H_5$ , which readily oxidises to the more stable corresponding azo-compound ( $C_6H_5)_3C.N:N.C_6H_5$ . This, when heated to 110°, gives off nitrogen, and from the residue is separated a white crystalline body, the analysis of which and its molecular weight, determined by the freezing point of its solution in naphthalene, agree with the formula  $C(C_6H_5)_4$ . The substance melts at 267° C., is soluble in hot benzene, but not in ether, acetic acid, or petroleum spirit.—J. T. D.

## New Books.

CHEMISCHER-KALENDAR, 1898. Von Dr. RUDOLF BIEDERMANN. 19ter Jahrgang. Mit einer Beilage, Julius Springer, Berlin, N. H. Grevel and Co., 33, King Street, Covent Garden, London. 1898. Price 4s. 6d. post free.

THE 19th edition of the *Chemiker-Kalendar*, arranged in pocket-book form, has now appeared. It is strongly bound in cloth, contains almanack for 1898, and a table of frequently used atomic weights, and their multiples. A Chronological Table is added of the principal events in the history of the Sciences, more especially of Chemistry. A Note-book Calendar is also supplied, with blank pages for the different days of the year, wherein notes, data, &c. may be recorded. Tables next follow of specific gravities of Gases and Liquids, Salts and Alkaloids. Tables also of solubilities and properties of Inorganic Chemical Substances; another set being devoted to similar data for Organic Substances. The remainder of the Pocket-book is filled with tabulated data, &c. on the subjects of Qualitative and Quantitative Chemical Analysis, Volumetric Analysis, Spectrum Analysis, Gas Analysis, and Mineralogy.

The Supplementary Volume, or "Beilage zum Chemiker-Kalendar, 1898," is a separate Pocket-book in paper covers, more especially designed for Technologists. After a series of data, statistics, &c. of mathematical, physical, and general interest, the following groups of subjects receive special attention:—I. Water. II. Assaying. III. Fuels. IV. Sulphuric Acid. V. Alkali. VI. Bleaching Powder. VII. Nitre and Explosives. VIII. Ceramic Arts. IX. Glass. X. Mortar and Cement. XI. Illuminating Gas. XII. Starch and Sugar. XIII. Fermentation Industries. XIV. Fats and Oils. XV. Tannins. XVI. Textile Fibres and Paper. XVII. Photography. XVIII. Colours and Dyes. XIX. Physiological-Chemical Analysis. A series of useful recipes follows, and this concludes the work.

THE ANALYST'S LABORATORY COMPANION. A Collection of Tables and Data for the Use of Public and General Analysts, Agricultural, Brewers', and Works' Chemists, and Students. By ALFRED E. JOHNSON, F.I.C., &c. Second edition, enlarged and improved. J. and A. Churchill, 7, Great Marlborough Street, London. 1897. Price 5s.

8vo volume, containing Preface, Table of Contents, blank ruled sheet, 96 pages of subject-matter, alphabetical index, and eight blank ruled pages for notes. Interspersed throughout the body of the work also, there are similar blank ruled pages for the record of notes.

The work, as indicated in the title, is mainly a collection of tables and formulae for analysts. They are as follows:—Atomic Weights. Notes on Indicators. Precipitating Powers of Common Reagents. Molecular Weights and Percentage Composition of commonly occurring Compounds. Weight of 1 litre of various Gases. Multipliers and their Logarithms required in Gravimetric and Volumetric Analysis. Notes on and Table of Logarithms. Useful factors, &c. Signs used in Medical Prescriptions. Useful Data. Tables required in Water Analysis, &c. Barometric Tables. Correction of Volumes of Gases for Temperature. Tension of Mercury Vapour. Tables for Beer Analysis. Specific Rotatory Power of the Carbohydrates; also their Cupric Reducing Powers. Phosphate Table. Ammonia and Albuminoid Table. Kjeldahl Process. Quinine. Chocry in Coffee, estimation of. Quinine Sulphate. Baume's Hydrometer. Alcohol Tables, &c. Butter and Milk Analysis. Glycerin. Correction of Standard Solutions for Temperature.

THE PRINCIPLES AND PRACTICE OF BREWING. By WALTER J. SYKES, M.D., F.I.C., &c., Editor of the *Analyst*. With plate and numerous illustrations. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London. Price 21s.

THIS work is dedicated to Dr. Emil Chr. Hansen. It contains 495 pages of subject-matter, list of principal books consulted, filling one page, and appendices, six pages. There are also the preface and alphabetical index, and the work is illustrated with 72 wood engravings.

The text is sub-divided as follows:—PART I.—I. Physical Principles involved in Brewing Operations. II. Chemistry, with special reference to the Materials used in Brewing. PART II.—III. The Microscope. IV. Vegetable Biology. V. Fermentation. PART III.—VI. Water. VII. Barley and Malt. VIII. Brewery Plant. IX. Brewing. X. Beer and its Diseases. Bibliography. Appendix A. Solution Weight and Solution Factor. B. Specific Rotatory Power. C. The Law of Definite Relation. D. Alcoholic Fermentation without Yeast Cells. E. Fermentation in a Vacuum. On page 42, is a handsome plate illustrating the arrangement of the atoms of a molecule in space.

SOME NORTH AMERICAN CONIFERÆ, being a series of papers reprinted from the *American Journal of Pharmacy*, January 1896 to July 1897. By EDSON S. BASTIN and HENRY TRIMBLE. *American Journal of Pharmacy*, Philadelphia, U.S.A. 1897.

THIS work is in pamphlet form and of 8vo size. It contains preface and 124 pages of subject-matter, and is illustrated with 58 wood engravings and two plates, one illustrating the *Pinus Strobus L.* and the other *A branch of Tsuga Canadensis*. The further extension of the work was brought to an untimely end through the death of Prof. E. S. Bastin. The principal points in the contents are as follows:—Classification and Distribution. Chemical Composition. Economics. Varieties of *Pinus*. Physiology of the Resins. Turpentine Industry. Tar. General Characters of the Spruces. Varieties of Spruce, &c. *Abies*, General Characters, &c. *Tsuga*, General Characters, &c. Hemlock Tannins.

## Trade Report.

### TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

NEW CUSTOMS TARIFF OF CANADA.

(Continued from page 836.)

SCHEDULE B.—Free Goods.—(continued).

No.	Article.
522	Firebricks, for use in processes of manufacture, or for manufacturing purposes.
528	Foot grease, being the refuse of cotton seed after the oil has been pressed out, but not when treated with alkali; and grease, rough, the refuse of animal fat, for the manufacture of soap and oils only.
531	Gums, viz.:—Amber, Arabic, Australian, copal, damar, elemi, Kaurie, mastic, sandarac, Senegal, shellac; and white shellac in gum or flake, for manufacturing purposes; and gum tragacanth, gum gouda and gum barbery.
536	Hides and skins, raw, dry or wet, and raw pelts.
547	Lampblack and ivory black.
550	Lime juice, crude only.
556	Nickel; and ores of metals of all kinds; and silex or crystallised quartz.
558	Oils, viz.:—Cocoonut and palm, in their natural state; and carbolie or heavy oil; oil of roses and otto or attar of roses, and olive oil for manufacturing soap or tobacco, or for canning fish.
559	Oil cake and meal, cotton cake and meal, and palm-nut cake and meal.
561	Oleostearine and degnas.
564	Platinum wire and platinum in bars, strips, sheets, or plates; platinum retorts, pans, condensers, tubing, and pipe, when imported by manufacturers of sulphuric acid for use in their works in the manufacture or concentration of sulphuric acid.
565	Potash, muriatic and bichromate of, crude, caustic potash, and red and yellow prussiate of potash; also pot and pearl ash, in packages of not less than 25 lb. weight.
568	Quicksilver.
570	Rags, paper waste, and any waste other than mineral.
573	Rubber and gutta-percha, crude, caoutchouc or india-rubber, unmanufactured; powdered rubber and rubber waste; hard rubber in sheets, but not further manufactured, and recovered rubber and rubber substitute.
575	Rubber thread, elastic.
579	Salt, imported from the United Kingdom, or any British possession, or imported for the use of the sea or gulf fisheries.
584	Silver, nickel and German, in ingots, blocks, bars, strips, sheets, or plates, unmanufactured.
586	Soda, sulphate of, crude, known as salt cake, barilla, or soda ash, caustic soda; silicate of soda in crystals or in solution; bichromate of soda, nitrate of soda, or cubic nitre, sal soda, sulphide of sodium, nitrate of soda, arseniate, binarsenate, chloride, chlorate, bisulphite, and stannate of soda.
610	Tin, in blocks, pigs, bars, and sheets, tin plates, tin crystals, tin strip waste, and tin foil, tea lead.
618	Turpentine, raw or crude.
621	Ultramarine blue, dry or in pulp.
622	Varnish, black and bright, for ships' purposes.
624	Whiting or whitening, Paris white, and Gilder's whiting, blanc fixe, and satin white.
632	Yellow metal, in bolts, bars, and for sheathing.
633	Zinc spelter and zinc in blocks, pigs, sheets, and plates; and seamless drawn tubing.
634	Molasses, second process, or molasses derived from the manufacture of "molasses sugar," testing by polariscope less than 35 degrees, when imported by manufacturers of blacking, for use in their own factories, in the manufacture of blacking, conditional that the importers shall, in addition to making oath at the time of entry that such molasses is imported for such use and will not be used for any other purpose, cause such molasses to be at once mixed in a proper tank made for the purpose with at least one-fifth of the quantity thereof of cod or other oil, whereby such molasses may be rendered unfit for any other use, such mixing to be done in the presence of a Customs officer at the expense of the importer, and under such further regulations as are from time to time considered necessary in the interest and for the protection of the revenue, and that until such mixing is done and duly certified on the face of the entry thereof by such Customs officer the entry shall be held to be incomplete and the molasses subject to the usual rates of duty as when imported for any other purpose.

#### Schedule C.—Prohibited Goods.

639	Oleomargarine, butterine, or other butter substitute.
-----	---

(For Schedule D, see this Journal, June 1897, p. 573.)

In addition to the above schedules regulating the import duties, the following Act respecting export duties was also assented to on the 29th June last:—

2. The Governor in Council may, by proclamation published in the *Canada Gazette*, impose export duties, as under, upon the following ores and metals, and each such duty shall be chargeable accordingly after the publication of such proclamation; and the Governor in Council may, by proclamation published in like manner, from time to time remove and reimpose such export duties:—

(a.) On nickel contained in matte or in the ore, or in any crude or partially manufactured state, and upon copper contained in any matte or ore which also contains nickel—when exported from Canada—upon such nickel, an export duty not exceeding 10 cents per lb., and upon such copper, an export duty not exceeding 2 cents per lb.

(b.) On ores which contain copper or any metal other than nickel or lead, when exported from Canada, an export duty not exceeding 15 per cent. on the value of the said ores.

(c.) On lead ores, and on lead and silver ores, when exported from Canada to a country which imposes an import duty on lead in bars or in the form of pig lead in excess of the import duty on lead contained in lead ores or in lead and silver ores—an export duty on the lead contained in the ores so exported from Canada, to an amount per pound equivalent to such excess.

#### CANADA.

##### Declarations as to Origin of Goods.

A report, dated 28th October last, has been received at the Board of Trade from the Secretary to the High Commissioner of Canada, stating that a telegram has been received from the Minister of Customs of Canada to the effect that declarations of the origin of goods may now be made before any witness. Prior to the modification of the regulations the declarations were required to be signed before a magistrate, justice of the peace, chamber of commerce, or notary public.

#### NEW ARGENTINE LAW IN REGARD TO THE SALE OF MEDICINES.

*Scientific American*, Oct. 30, 1897, 275.

The Congress of the Argentine Republic is expected to pass a law creating a national board of health (or Department of Public Health, as it is called officially). The law will become effective in a short time. This board of health will have complete control as to what medicines or compounds shall be allowed upon the Argentine market, as will appear from the following two articles of the law:—

Article 36.—It shall be lawful to sell or to expose for sale in any pharmacy or apothecary's shop or store such specialties or compounds only whose component parts are clearly specified upon a visible part of the package thereof, setting forth also the doses of the active substances contained therein.

Article 37.—The Department of Public Health will authorise the sale of the medicines referred to in Article 36, when the required conditions have been fulfilled, without which authorisation such goods cannot be offered for sale.

Failure to comply with the requirements of these two articles will be punished by a fine of from 100 dolrs. to 200 dolrs.

It will therefore become necessary for American manufacturers exporting medicinal compounds and specifics to the Argentine Republic to obtain the required permit from the Department of Public Health, and to state the composition of the medicine on each package.

#### CHANGES IN THE AMERICAN PATENT LAW.

*Chem. Trade J.*, Nov. 13, 1897, 312.

Mr. J. C. Chapman, Fel. Chart. Inst. of Patent Agents, calls attention to some important changes in the American patent law which, by an Act of Congress, will come into force on the 1st of January next. Hitherto an inventor could always obtain an American patent if he applied at any time during the life of his English or foreign patent for the same invention, provided such invention had not been

in public use in America for more than two years before his application. This was a most generous law. Under the new Act, however, an inventor will not be able to obtain a United States patent for an invention unless he applies within seven months from the date of his application for his English or other first foreign patent for the same invention; Those who now have English or foreign patents granted for any invention, therefore, have still time to obtain, if they so desire, a United States patent for the same invention; but they must apply before January 1st, 1898, in order to protect the invention under the provisions of the present law. They will lose the right when the new law comes into operation. If, therefore, inventors here have not already applied, and desire protection in America, they must act at once.

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

REPORT OF THE WEST INDIA ROYAL COMMISSION, WITH  
SUBSIDIARY REPORT BY D. MORRIS; AND APPENDICES.

*Government Blue Book, 1897, 1—174.*

This Commission comprised Sir Henry Norman, Sir David Barbour, and Sir Edward Grey, the first-mentioned being the chairman. The report of the Commission is divided into three parts. Part I. deals with general questions affecting the economic conditions of all the West Indian colonies. Part II. deals with each colony in detail, and shows the great difference which exists between their several conditions. Part III. comprises the conclusions drawn from a consideration of the whole.

The total exports, excluding Jamaica, and gold from British Guiana, were 3,945,000*l.*, of which 2,951,000 (75 per cent.) were products of the sugar cane. The following table, furnished to the Commissioners by A. G. Bateman, of the Board of Trade, shows the average prices at which refined and unrefined sugar were imported into the United Kingdom in each of the last 16 years:—

Years.	Refined and Candy.		Unrefined.	
	Lumps or Loaves.	Other Sorts.	Beetroot.	Cane and other Sorts.
	Per Cwt. <i>s.</i>	Per Cwt. <i>s.</i>	Per Cwt. <i>s.</i>	Per Cwt. <i>s.</i>
1881		28'93		21'72
1882	29'14	28'03	21'15	21'09
1883	27'07	26'73	19'98	20'19
1884	21'79	20'15	11'16	16'41
1885	18'82	17'83	12'35	14'56
1886	17'67	16'34	11'96	13'85
1887	16'33	15'39	11'80	12'53
1888	18'58	17'20	13'05	13'84
1889	20'59	19'44	14'33	16'00
1890	17'22	16'08	12'25	13'33
1891	17'42	16'30	12'71	13'28
1892	17'97	16'83	13'11	13'18
1893	19'55	18'11	14'38	14'20
1894	16'97	15'18	11'21	12'22
1895	14'45	13'05	9'32	10'09
1896	14'75	13'33	10'34	10'85

Although, as shown above, the products of the sugar cane constitute the larger portion of the total exports, yet, in view of the fall in prices of sugar, the Commissioners conclude that cane cultivation is no longer profitable, and neither are there any good grounds for supposing that any marked rise in price is likely to occur in the immediate future; indeed, the prices for 1897 have ranged much below those of any previous year. The depreciation in the value of by-products—molasses and rum—has also contributed appreciably to the present depression.

The depression of the industry is due to the competition of other sugar-producing countries, such as the United States, Argentina, and Egypt, and in a special degree to the competition of beet sugar produced under a system of bounties. It is also affected by high protective tariffs and by the competition of beet sugar, the production of which is specially encouraged by the Governments concerned. The

causes of the depression may be considered permanent, inasmuch as they are largely due to the policy of foreign countries, and there is no indication that such policy is likely to be abandoned.

The evidence brought forward does not show that the depression arises from extravagance in management, or to imperfection in the process of manufacture, or to inadequate supervision consequent on absentee ownership; and the removal of these causes, when existing, would not enable it, generally, to be profitably carried on under present conditions of competition. In many places in the West Indies—Barbados, St. Vincent, Dominica, Antigua, &c.—sugar is not manufactured according to the best and latest processes; but even the estates which have introduced the best machinery suffer from the depression, and the Commissioners consider that improvements would be more general out for the apparently well-founded conviction that even with the assistance of such machinery the working could not be profitably carried on. In places where, owing to local causes, large factories, equipped with the best machinery, cannot be established, it is doubtful if the sugar industry could, under any circumstances, be restored to a condition of permanent prosperity, except, perchance, in localities which enjoy very special advantages in soil, climate, and labour supply.

Owing to the crisis, many of the estates are being and have been abandoned, and the consequent distress among the labouring population will render it impossible for most of the islands to provide for their own government and administration without external aid.

In the event of the production of sugar being discontinued or largely reduced, there are no industries which could replace it in such islands as Barbados, Antigua, and St. Kitts, and be profitably carried on and supply employment for the labouring population. In most of the other islands other industries may be substituted for that of sugar, but only after the lapse of a considerable period and at the cost of much displacement of labour, and consequent suffering. The Commissioners consider that in all colonies where sugar can be replaced by other industries, the colonies in question will be in a much sounder position, both politically and economically.

The best remedy for the present state of affairs would be, if the continental nations could be induced to abandon the bounty system; but taking into consideration the great cheapening of the cost of production of beet sugar and the fact that many countries appear to have singled out the sugar industry as one which ought to be artificially stimulated in various ways, it is not clear that, even if the bounties were abolished, another crisis of a similar character might not arise in the West Indies at a future day. A remedy which was largely insisted on by witnesses interested in the sugar estates, and supported by the chairman, was the imposition of countervailing duties on bounty-fed sugar when imported into the United Kingdom. This course, however, was not approved by the majority of the Commission. The chairman has stated his views separately on this point.

The following are the special remedies which were unanimously recommended:—

1. The settlement of the labouring population on small plots of land as peasant proprietors.
2. The establishment of minor agricultural industries, and the improvement of the system of cultivation, especially in the case of small proprietors.
3. The improvement of the means of communication between the different islands.
4. The encouragement of a trade in fruit with New York, and, possibly, at a future time, with London.
5. The grant of a loan from the Imperial exchequer for the establishment of central factories in Barbados. The remedies in 2, 3, and 4 would amount to 27,000*l.* for 10 years, whilst the last-mentioned would cost 120,000*l.*, and no doubt involves the risk of loss. The smaller islands require a grant of 20,000*l.* a year for five years for ordinary expenditure of an obligatory nature; and immediate grants of 30,000*l.* are necessary for roads in Dominica and St. Vincent, to enable the settlement of the labouring population on the land to be carried out; and 60,000*l.* to clear off the floating debt in some of the smaller islands.

Appendix A comprises a report by Dr. Morris, in which he systematically discusses the islands and their industries.

He recommends the establishment of a department of economic botany and for agricultural instruction in the West Indies, and appends a scheme for this purpose.

Appendix B contains tables of statistics, with illustrative diagrams and a map of the West Indian colonies.—J. L. B.

#### Erratum.

##### SULPHATE OF COPPER.

(This Journal, Oct. 1897, 838.)

Replying to a special inquiry made by the United Alkali Co., Messrs. Rinow-Kessel and Co., of Cologne, state, in regard to the ruling prices of sulphate of copper during 1896 and 1897, that the average value in 1896 was about 16l. per ton, with a fluctuation to 18l. 10s. during March until June. In 1897 there was a similar average price, *viz.*, 16l. 5s., with the exception of January to middle of April, when 17l. 10s. to 19l. was paid. The figures quoted from Foreign Office Report No. 1977 are therefore clearly wrong.

#### SWITZERLAND.

##### Tariff Decisions.

A despatch has been received at the Foreign Office from H.M. Minister at Berne, forwarding the following list of articles not previously mentioned in the Swiss tariff, but which are now included:—

No.	Article.	Rate of Duty.
13	Extract of the kola nut .....	Per 100 kilos. 10 <sup>00</sup> 0
15	Nitrate of silver .....	" 8 <sup>00</sup> 0

#### UNITED STATES.

##### Tariff Decisions.

Phthalic anhydride or phthalic acid anhydrous is assessed for duty at 20 per cent. *ad valorem*, under paragraph 19 of the Tariff Act of October 1, 1890.

Tetrachlorophthalic anhydride is not an acid, and is dutiable at 20 per cent. *ad valorem* under paragraph 19 of the Tariff Act of 1890.

#### COMMERCIAL AGREEMENT WITH BULGARIA.

*Bd. of Trade J.*, Nov. 1897, 514.

By an annex to a commercial agreement between Great Britain and Bulgaria, which was signed at Vienna in July last, the import duties on the goods specified below are not to exceed the rates scheduled as follows:—

1. Copper, in ingots, plates, and sheets, 10 per cent. *ad valorem*.

2. Caustic soda and soda of all kinds; potash; alums of all kinds; carbonate of ammonia; sal ammoniac; spirit of salt of ammonia and sulphate of ammonia; green and blue vitriol, 12 per cent. *ad valorem*.

#### PRODUCTION OF TARTARIC MATERIALS IN ITALY.

*Bd. of Trade J.*, Nov. 1897, 591.

Mr. E. Neville Rolfe, H.M. Consul at Naples, in a report to the Foreign Office, dated 14th October, says that the total production of tartaric materials in Italy for the 12 months ended 30th September 1897, amounted to 9,312 tons, of a value of 366,500l. The exports to the United Kingdom were 2,988½ tons; to the United States, 3,470½ tons; to Germany, 509 tons; to France, 216 tons; and to other countries, 2,158 tons.

#### CALCIUM CARBIDE.

*U.S. Cons. Reps.*, Nov. 1897, 331.

The Aluminium-Industrie-Actien-Gesellschaft, in Neuhausen, Switzerland, and The Electrochemische Werke G. m. b. H., in Bitterfeld, Germany, manufacture calcium carbide which averages 79 per cent. purity: from this percentage 3,118 kilos. (6,002·9 pounds) of calcium carbide are necessary to produce 1,000 kilos. (0·875 cb. m.\*) of

acetylene. It is impossible to ascertain the cost of the production of calcium carbide from either of the above-mentioned factories, but taking as a basis the lowest wholesale price of the carbide at 40 mks. per 1,000 kilos., then 1,000 kilos. (0·875 cb. m.) of acetylene will cost 1,217·20 mks.

It may be further added that, in addition to the above use of calcium carbide, it can be used advantageously in metal refining, especially for reductive purposes in the manufacture of ingot iron.

The following prices are charged by the Electrochemische Werke G. m. b. H., in Bitterfeld: On small orders, 60 mks. per 1,000 kilos.; large orders, 450 mks. per 10,000 kilos., and if a large and steady trade were created, the price would fall to 100 mks. per 10,000 kilos. These prices are for the calcium carbide, loaded in the ship at Hamburg, but do not, however, include packing. The steamship companies demand that the carbide be packed in iron cylinders or drums containing 200 kilos. These cylinders must not only be water-tight, but also encased in a tight box or barrel. The cost of packing is 8 mks. per 200 kilos.

Great difficulty has been heretofore experienced in the shipment of the carbide, but it has recently become easier and probably would become more so were the demand large.

The above-mentioned factory in Bitterfeld is the only one in Germany where calcium carbide has been manufactured to any large extent. They are now constructing a larger branch in Rheinfelden, near the Swiss frontier, where there is a very great water power. This new place will be finished in the early fall. As soon as their dynamos are run by water power their prices will become somewhat lower.

#### GENERAL TRADE NOTES.

##### BERLIN TRADE AND INDUSTRY, REPORT FOR 1896.

*Ber. über Handel u. Industrie, Berlin, 1896.*

**METALS** (pp. 170—172).—*Tin* further declined in value, rates—varying between 136 and 128 m. per 100 kilos.—sinking until in October they touched 120 m.; and, though the closing prices revived to 128—130 m., the average for the year was the lowest on record. An increased consumption and decreased production—many mines being closed on account of unremunerative prices—have reduced stocks, but a change for the better is believed to be imminent.

The consumption of *copper* increased everywhere, except in America, so that the increased shipments—109,000 tons against 65,000 in 1895—to Europe from that country were rapidly taken up. This notwithstanding, European stocks in sight at the close of the year had shrunk by 11,000 tons. Electrical appliances, in which Berlin does a large trade, the growing brass industry, and copper sulphate for treating vines, were mainly responsible for the improved demand.

Speculative purchases forced Berlin rates for the metal from 93—100 m. up to 117—112 m. in June, and after receding to 104—108 m. in August, they closed at 109—112 m. per 100 kilos., this rise being chiefly due to the improved demand. Mansfeld copper was saleable in increased quantities at equal rates with English and American sorts.

*Antimony regulus* was in better demand, though the quantity used is small; and rates varied between 68 and 60 m. per 100 kilos., with an upward tendency at the close.

*Lead* was in good demand throughout the year, and in the last quarter there was a slight general advance in rates due to improved economic conditions in America and the scarcity of local stocks. Except for special purposes, American lead forms the main article in Berlin trade, being usually 4 per cent. to 5 per cent. cheaper than the German grades (23—24 m. against 24—26 m. per 100 kilos.). The outlook is considered favourable, but higher prices are necessary to enable German producers to make at a profit.

*Crude Zinc*.—The year was a very favourable one, and prices rose steadily, with but slight interruptions, from 32 m. per 100 kilos. in January to 38—39 m. in June. In anticipation of an over-production, cheaper offers were made in the third quarter for October delivery, and, in

\* 1 cb. m. = 35·316 cb. ft.

fact, prices receded 3 m. transiently in September, only, however, to again rise to 38 m. at the end of the year, the increased production being rapidly taken up by consumers, and makers were well sold forward for delivery in the first quarter of 1897. It is, therefore, assumed that rates will remain firm, and perhaps even advance.

**Zinc plate** was also in a constantly increasing demand, prices rising from 38·50 m. to 45 m. by June and remaining firm for the rest of the year, in spite of a partial weakening of London quotations and rates for crude zinc. Makers were full of orders.

In the *tinplate industry* prices were forced down by the low offers of English manufacturers. Large contracts had to be placed in England, the imports increasing from 1,400 tons in 1895 to 10,400 tons in 1896. In the second half of the year German makers again came on the market, and, the South Wales strike having raised English prices, the outlook for 1897 became more favourable. The consumption of tinplate in Berlin and Brandenburg is steadily growing, but the profits of the wholesale trade are as steadily decreasing.

**DRUGS** (pp. 193—195).—The position of the export trade is satisfactory, owing, it is said, to the commercial treaties. Russia is still Germany's best customer, but the exports to Central and Southern America, as well as Eastern Asia, have increased, though the trade with the United States has declined, as is also the case—from political considerations—with Turkey, Cuba, and the Philippines; whilst the Scandinavian connection is still maintained.

**Camphor**, the use of which for technical purposes is increasing, has become an object of speculation, and a London syndicate forced prices up from 260 m. to 480 m. per 100 kilos., but they afterwards subsided, and closed at about 275 m.

**Quinine** suffered a decline in rates from 50 m. to 35 m., through the increased production in Java, which country shipped some 2 million lb. more than in 1895.

**Cocaine**.—The cultivation is extending in Peru and Bolivia, and semi-purified cocaine is now exported. Germany received some 2,000 kilos. of crude cocaine and 5,000 bales of coca leaves. The pure drug declined in price from 520 m. to 410 m. per kilo.

**Fish Liver Oil**.—The poor catch in the cod fishery caused prices to go up from 130 m. to 200 m. per 100 kilos., but the restricted consumption and the introduction of inferior oils into the market produced a relapse to 160 m.

**Lactose**, though extending in use for infants' food, is not made so largely in Germany as formerly, America being now a large exporter, instead of buyer, of the article.

**Edible olive oil** rose 10 per cent. in price in consequence of the poor and late crop and the increased demand for preserving the unusually large catch of sardines.

A reduction of 20 per cent. was made in the price of *salicylic acid* to compete with foreign producers and prevent the erection of new factories.

**Spirits** followed the rapid rise in the price of potatoes, but receded on the crop being found to exceed expectations.

**Vanilla** held its ground against the competition of vanillin, without any serious depreciation of values.

**DYESTUFFS** (pp. 196—197).—**Indigo**.—Notwithstanding the large crop (162,200 factory maunds) in the Bengal Provinces, the anticipations of lower prices were not realised, and early purchase of Oudh and Benares indigo showed an advance of 10 and 30 rupees per maund, 340 r. being paid for good marks. However, values subsequently receded to from 20—25 r. above 1895 averages. Notwithstanding the rise in exchange the continent continued to import largely, and although a good deal of 1895 stock was left over, trade was brisk, especially when unfavourable reports were spread with regard to the new crop, until it was found that the production would reach 142,000 maunds, whereupon stagnation set in. The quality of the 236,200 bazaar maunds produced in the Madras Provinces was inferior, and prices ruled lower than for Calcutta sorts. Java produced 680,000 kilos. (76,000 kilos. increase) of good quality, and the crop turned out better than that of India. The Guatemala crop was small, and the high price restricted consumption.

**Dyewoods**.—An excess of imports caused prices to fall, especially towards the end of the year. Supplies of good Laguna-Campeachy logwood were scanty, but medium and inferior grades were in greater quantity than usual, as was also the case with Yucatan and Campeachy sorts, shipments of these latter mostly turning out well, particularly the Cuyo and pure Yucatan qualities. Domingo and Haiti logwoods are out of favour in this market. Saint Marc turned out satisfactory, and Aux-Laves supplied good quality, Montecristi roots being better known than usual. Jamaica trunks were scarce, but roots enjoyed a good share of attention.

**Fustic**.—Shipments from Savanilla and Carthagena were short, and from Maracaibo altogether lacking. Corinto exported but very little, and prices might have recovered, but for the large consignments from Mexico (Vera Cruz).

**Redwood**.—The shipments from Vera Cruz greatly increased, and prices ruled low.

**Quebracho**.—Prices fluctuated until summer, but then became firmer. Higher freights, large contracts for Argentina, and the more settled state of the trade after the rejection of the Quebracho tariff by the Reichstag, acted favourably on this article.

**Dyewood Extracts**.—A large turnover was again done, but prices fell in sympathy with those of the dyewoods.

**Catechu**.—A few large contracts were made, but prices receded at the close of the year.

A large turnover was done in *terra japonica* blocks and cubes, prices falling in summer, so that closing quotations were lower than at the end of 1895.

**Myrabolans**.—The low rates of 1895 experienced a further devaluation. Little trade was done, and only very recently has the market hardened, in consequence of epidemics in the producing centres, and higher freights and exchange.

**PETROLEUM** (pp. 197—198).—The imports of refined oil into Berlin totalled 72,733,468 kilos., an increase of about 3,700,000 kilos. for the year, and almost equal to the figures for 1894; and as 2,800 barrels of naphtha and benzene were also received, the total consumption amounted to about 101,270 barrels of 180 kilos. gross. It is thus evident that the competition of the incandescent gas light has little effect on the petroleum trade. Prices fluctuated from 22·50 m. per 100 kilos. in January, to a minimum of 19·40 m. in April—May, rising again steadily to 22·20 m. by the middle of November, but afterwards receding to 20·80 m.

Three-fourths of the total oil used was "water-white," but sundry complaints arose with regard to the burning quality.

Favourable reports were received from consumers on the mixtures of Russian and American oils introduced as an experiment.

**BONES AND OTHER FERTILISERS** (pp. 198—199).—The price of *bones*, after falling, early in the year, to a level seldom attained, remained steady, and a good business was done.

**Fertilisers** again receded in value through the action of agricultural associations, keen competition, and increased production.

**Bone meal** was in small request, and prices fell to about half the rates current a few years back; and had it not been for the increased value of bone gelatin, many works would have had to close.

**Superphosphate**.—Although the dividends paid by producing companies in 1895 only averaged 3·75 per cent., prices experienced a further decline, owing to the competition of Thomas-slag meal, coupled with the increased production of superphosphate, in order to consume the large amounts of sulphuric acid lacking use, on account of the substitution of electrical processes in the manufacture of soda, chlorine, &c. Ocean freights falling caused a better inquiry for Florida phosphate as raw material, at the end of the year, and the market weakened once more.

The consumption of Thomas-phosphate meal remained at its old figure.

The large shipments and low offers of *nitrate of soda* depressed values of all nitrogenous manures. Prices ranged between 7·50 and 8·50 m. per centner, free Hamburg, and 535,250 tons were received at that port and Harburg.

**Extracted Bone Fat.**—The demand was low, and prices fell to below 30 m. per 100 kilos., without prospect of recovery.

**Bone Gelatin.**—A good demand prevailed, both at home and abroad, throughout the year, and prices improved considerably.

**Degelatinised bone meal** sold at 5—5½ m. per 100 kilos., chiefly for shipment to Sweden and England, whilst *undegelatinised* meal, selling at about 7 m. per 100 kilos., was difficult to dispose of, owing to foreign competition.

**Hornmeal, Bloodmeal, Fishmeal, and Leathermeal** all suffered from the competition of mineral nitrogenous manures, and met with merely a restricted application.

**OILS AND FATS** (pp. 199—290).—The official figures of imports to Berlin were:—Olive and edible oil, 86,540 kilos.; dematured olive oil, 841,685 kilos.; linseed oil, 1,177,856; cotton-seed oil, 794,581; palm- and cocoa-nut oil, 4,866,658; rape and other oils, 171,272; fish oil and blubber, 180,688; tallow and animal fats, 2,513,844 kilos.; all—except the first two items and palm oil—being inferior in quantity to the previous year's trade. Business was dull and prices weaker throughout.

**Linseed oil** was chiefly derived from the Harburg and Breslau crushers, the supplies drawn from England and Holland being much smaller than formerly. Prices for good, clear oil ranged from 32—42 m. per 100 kilos.

**Cotton-seed oil** was shipped largely from England and America, the very white grades from the latter country increasing in favour. Rates for pale, double-refined varied from 45 to 39 m.; extra pale, 2 to 4 m. higher.

**Hemp oil** is now scarcely ever used. Prices, 70—67 m.

**Olive Oil**—This was chiefly the cheap Levant oil, Spanish oil not being offered later than autumn, owing to a deficient crop. Prime Smyrna was quoted at 69 m., falling to 62 m. and recovering 1 m. later; Malaga, 66—63 m.; green sulphur oil, 48—45—42 m.

**Palm oil** receded in sympathy with tallow, but short supplies in autumn sent rates up again. Prime Lagos, after falling from 50 to 43 m., recovering to 49—48 m.

Imports of **cocoa-nut oil** are small, the Harburg and Magdeburg coprah crushers being able to meet the demand. Cochin oil cost 64—63 m., and inland coprah oil 53—51 m.

**Palm - kernel oil**, also home-crushed, ranged from 47 to 42 m.

**Tallow** was dull throughout the year, the large stocks of 1895 shipments in London preventing any rise beyond a transitory advance in autumn due to speculative dealings. Inland candle tallow fell from 58 to 48 m., and soap tallow from 50 to 40 m.; Australian from 50—56 m. to 42—48 m.; and the small quantity of Russian lubricating tallow imported, from 90 m. to 80 m.

**Olein** touched very low prices, owing to the cheapness of tallow and the slack demands of the textile industry. Prices ruled: for saponified olein, 54—48 m.; distilled, 38—41, 47—51 m.; St. Petersburg Newsky, 51—48 m.

**Fish oils** rose in price until June, the better news from the seal fishery and the slow demand then causing a relapse. Greenland seal oil, 48—49—47 m.; Berger liver oil, 50—51—48—44 m.

**Fats** were plentiful, and prices declined, natural bone fat falling from 43 to 35 m., benzine fat from 36 to 30 m., and fuller's grease from 34 to 28 m., for medium qualities.

**Mineral Oils.**—The supplies from America and Russia were regular, at prices varying from 19 to 28 m. for low grades, 30—42 m. for medium, and 50 to 80 m. for heavy cylinder oils.

**THE BERLIN CHEMICAL INDUSTRY** (pp. 201—207).—In general, the 1896 trade was equal to that of the previous year, the volume of business being even greater. As a result of restrictive tariffs the export of tartar emetic to Austria, and of salicylic acid, salts of bromine and iodine, &c. to Italy, was prejudicially affected, and attempts were made in vain to procure a reduction in the Russian duty on lithopone. In the export of aniline colours to Spain, German makers are still at a disadvantage as compared with French and Swiss producers.

The chemical industry continues to be hampered by the conditions of the regulations affecting the granting of permission to found and extend industrial establishments.

**Nitrogenous raw materials** were all depressed, the market being overloaded. **Sulphate of ammonia** continued to fall until the price touched about 15 m. per 100 kilos. works, owing to the unusual activity of the coke factories (necessitated by the demands of the iron industry) and the large stocks of the article in England. **Ammonium carbonate** also receded in price to 60 m., and **ammonia** was unable to resist the downward tendency, technically pure (sp. gr. 0.910) ammonia declining from an initial value of 30 m. to a closing price of 24.50 m. Increased competition forced white crystalline **sal ammoniac** down to 50 m. per 100 kilos.

A brisk trade was done in 96—98 per cent. **potash**, and prices remained firm, the quotations for Stasfurt crude potash salts contributing thereto. The same applies to **oxalic acid** and **acalates**, owing to the limitation of output by the international associations.

**Chlorate of potash** fell to the record low price of below 70 m. per 100 kilos., as a result of new cheap electrolytic methods of production.

**Calcined Glauber salt** was in very active demand, and the large stocks were all cleared out, a rise in values being the result. In **soda crystals** the competition of makers brought prices down to a rate barely remunerative for many works, since calcined soda remained unchanged.

**Water-glass (Alkali Silicate).**—A continuance of over-production caused the suspension of two works. Home consumption was normal, but the increased Russian tariff has killed the former large trade with that country, and Austro-Hungary buys less than formerly, the high duties having encouraged the erection of works for producing this article.

In **sulphuric acid** and **nitric acid** there was a large trade at but barely remunerative prices, and little profit was made on **hydrochloric acid**.

**Methyl Alcohol.**—Increased competition forced prices down. A new undertaking made large forward sales at low rates and thus unsettled the market, but at the end of the year was not yet in a position to turn out any merchantable product. The expected rise in the price of **acetic acid** in America was not realised, and consequently **acetic acid** quotations fell still further.

**Carbon bisulphide** was in such good demand that there was difficulty in meeting all requirements. Values rose in sympathy with sulphur.

**Carbon tetrachloride** first came into prominence during the past year, and, being innocuous, has a satisfactory future before it, since the price is capable of reduction by the better utilisation of the by-products.

**Sulphur chloride** was in regular demand at firm prices, and the same applies to all preparations of **manganese**, such as the crystallised dehydrated chloride.

**Liquid carbondioxide** had an increased consumption among beer retailers and aerated water makers, the volume of trade in Berlin being 11 per cent. better than in the previous year. The exports from Berlin to northern countries diminished through the competition of makers in the Baltic ports, and the same effect was produced in Austria and Russia by high tariffs. The Rhine-land monopolises the trade with western countries, owing to the cheaper and better natural dioxide produced there, and the cheap water carriage.

The favourable situation of the **tar industry** was maintained, great activity prevailing in all branches, with satisfactory financial results, and an improvement in the rates for oils for painting and steeping purposes.

The **benzene** industry also pursued an unexpected course, the demand for colour making being so large that, notwithstanding the considerable extension of the production, prices rose from 50 m. at the outset to 120 m. per 100 kilos. by autumn. Although values have since receded to 80 m., it is hoped that the increasing demand will keep the price up to a moderately high level.

**Toluene, xylene**, and solvent **naphtha** followed, to some extent, the rise in benzene; and the **phenols**, particularly **naphthalene**, also rose in price. On the other hand,

*anthracene* suffered a serious decline in value, English stocks being still large, despite the large shipments of this article to Germany.

*Pyridine* remained unchanged until the close of the year, but then jumped up 25 per cent. in value, through a report that the English Government intended to sanction the pyridine process for denaturing spirit.

*Intermediate Products for the Tar Colour Industry.*—The consumption equalled that of 1895, but foreign competition kept prices down, though the raw materials experienced a rise in values.

*Aniline Oil and Aniline Salt.*—A good demand prevailed at prices proportionate to that of benzene.

Business was active in the *tar colour industry*, but the high price of benzene on the one hand and low selling prices on the other reduced profits. The unsettled state of the currency question and tariff in America, and the famine and plague in India, restricted the exports to those countries.

*Pigments and Mineral Colours.*—The trade with Russia, Austria, and Switzerland was crippled by restrictive tariffs. Japanese trade did not improve, and that with the United States declined.

The conditions were also unfavourable in the *varnish trade*, English firms being able, by reason of the low German tariff, to rule the market in varnishes and raw material, especially in copal, although most of this material originates from German colonies. It is therefore considered advisable to attempt to secure the sale and shipment of copal to German ports direct.

Unfavourable conditions prevailed in the *fat-extracting industry* by reason of apathy in the consuming industries and of the greatly increased shipments of Australian tallow and Indian linseed. This reduced the price of palm-kernel oil from 44 m. to 38½ m. per 100 kilos. *ex* Hamburg, and of linseed oil from 48 m. to 37 m. *ex* Hamburg. The large stocks and slackness of inquiry for feeding cakes and meals (*linseed cake, palm-kernel meal*) kept prices low, but a revival set in after the unfavourable potato and fodder harvests.

*Cerassin.*—The Galician ozokerite monopoly influenced this industry, and the increased price of the raw material (from 28—30 fl. to 34—36 fl. per 100 kilos. *ex* mine) led to the formation of a syndicate of German cerassin makers to raise the inland rate for the manufactured article.

*Pharmaceutical and Photographic Chemicals.*—A continuance of the favourable reaction that set in during 1895 is recorded.

*Ether and alcohol* remained fairly steady until the unfavourable potato crop sent prices up considerably in autumn.

The use of *sulphuric ether* in the textile industry experienced an extension.

*Bromine and Bromine Salts.*—In the former the associated producers in Stassfurt did not introduce any alteration in prices, but the competition among the manufacturers of bromine salts sent the profits on the latter down considerably.

*Boric and Boracic Acid.*—The volume of trade was satisfactory, but no settlement of prices could be arrived at, the associated producers having continually to face new competitors.

*Carbolic Acid.*—In anticipation of large State contracts, English prices for 39°—40° crystallised rose from 6½ d. to 8½ d. per lb., but afterwards receded to 7½ d.

*Diphtheric Antitoxin.*—The increased favour enjoyed by German serum was evidenced by the larger exports to England and America.

*Iodine and Iodine Preparations.*—In the latter articles the influence of the Association of European producers increased, but the associated iodine producers were embarrassed by the competition of shipments of crude iodine from extra-European lands, and the growing production in Japan crippled the export trade to that country.

*Glycerin.*—After a long period of settled prices, the unusually large purchases by America for 1896 delivery and the improved demand for dynamite-glycerin gave an impetus to rates, which was maintained until autumn, when, in consequence of accumulated stocks and the competition of foreign refiners, the market weakened.

*Lactic acid* (technical, 50 per cent.) found increased employment for textile purposes as a substitute for oxalic and tartaric acids.

In *tannin*, prices remained unchanged, owing to the great scarcity of galls nuts.

The use of *formalin* is extending, as is also the case with the preparation (*glutol*) of this substance and gelatin for the rapid healing of wounds.

The new industry (in Berlin) of *photographic materials* developed satisfactorily, the dry plates and papers made there being largely used.

**RAW AND DYED SILKS** (pp. 214—215).—A bad year has to be reported in both branches. The demand for silk for passementerie and fancy goods was small, and the prices current early in the year, owing to the unfavourable weather for the cultivation of the silk worm, had subsequently to give way on the realisation of a good crop, and now rule unusually low. Châpe silk moved downwards in sympathy; but tussah, being produced only in small quantities, found willing buyers at normal rates. Sewing silks experienced unfavourable conditions, being thrown on the market in quantities, in excess of the demand, at the lowest conceivable prices.

The average quotations for raw silks for the year, per 100 kilos., in Crefeld, less 5 per cent. for cash, or nett at nine months' date, were as follows:—*Italian*: organzine, 18 20, 42·33 m.; trame, 24 26, 36½ m.; grege, 12/14, 36½ m. *Japanese*: organzine, 22 24, 39·33 m.; tram, 34 40, 37¼ m. *Chinese*: tram, 36 40, 33·67 m.; these rates being from 1 to 4 m. below the 1895 average.—C. S.

#### PRODUCTION OF BEER IN JAPAN.

*Bd. of Trade J.*, Nov. 1897, 604.

The director and manager of the Osaka Beer Brewery Company, of Osaka, Japan, has, according to the *Journal of Commerce of Victoria*, informed an American journal that the beer production of his country is about 100,000 barrels per annum. The demand is extending, and his mission to the States was to supervise the manufacture of a new plant for brewing lager beer on the American system, and he intimated that, although he learned the brewing of lager in Bavaria, and has hitherto used that method, he finds American beer preferable. Further, that he proposes to use Japan and American barley and Californian hops. Australasian hops do not appear to have received his attention. Incidentally it was mentioned that the consumption of "sake," the native drink, made from rice, is as much as 5,000,000 barrels annually.

#### EXPORT OF MEDICINAL TINCTURES.

*Chem. and Druggist*, Nov. 20, 1897, 801.

During the first half of the present financial year—from April 1 to September 30 last—exporters of tinctures, medicinal spirits, &c., have had repaid to them the duty and allowances on 31,994 proof gallons of spirits exported in these articles, as against 25,619 proof gallons during the same period of 1896. This very substantial increase of 6,375 proof gallons would seem to indicate considerable activity in this section of the export drug trade during the six months in question.

#### CHINESE QUICKSILVER.

*Chem. and Druggist*, Nov. 20, 1897, 801.

The richest deposits of quicksilver known in the world are in the province of Kwei-Chow, in South-western China. Until now this province has been closed to foreign trade, but, by a treaty between Great Britain and China, which took effect on June 4 last, the West River, which taps this region, was thrown open to commerce for all nations, and on the evening of the same day the steamer "Wing Tong," of the China Navigation Company, left Hong Kong for a trading journey up the West River.

#### IMPORTED CHEMICALS IN JAPAN.

*Chem. and Druggist*, Nov. 13, 1897, 750.

The Bureau of Commerce of Japan supplies us with the following data concerning the import of chemicals. Ger-

many has it all her own way in the important branch of aniline dyes. It was so in 1893, when the order stood thus:—

Germany.	Switzerland.	France.	United Kingdom.	Belgium.	Holland.
Yen. 332,422	Yen. 49,943	Yen. 14,959	Yen. 8,393	Yen. 6,523	Yen. 1,800

It is so now. Germany, indeed, has improved her position, and increased her already considerable output in greater proportion than her competitors. Englishmen, the inventors of aniline dyes, have meantime fallen off and given up the fourth place on the list to Holland, which really means Germany, as aniline dyes are not made in Holland, but only shipped through Dutch ports. Here are the latest figures:—

Germany.	Switzerland.	France.	Holland.	United Kingdom.	Belgium.
Yen. 592,945	Yen. 59,533	Yen. 21,654	Yen. 4,950	Yen. 2,289	Yen. 1,543

In alizarin dyes Germany conducts practically the whole of the trade. France commenced a slight trade in 1894. The same holds good with alcohol, except that Great Britain is this time the slight competitor. In paint in oil Great Britain led in 1893, and has increased her lead in a striking manner. She now does practically the whole of the trade. Great Britain still leads in chlorate of potash. Germany and France have, however, doubled their output somewhat at her cost. The latest figures are:—

	Yen.
Great Britain.....	366,850
Germany.....	41,906
France.....	10,292

In salicylic acid Germany does all the business. Great Britain and France are simply nowhere. Great Britain is safe in the manufacture of amorphous phosphorus. France just tries to compete:—

	Yen.
Great Britain.....	248,383
France.....	2,315

The same holds good in caustic soda. America entered into competition in 1893, while Germany fell out:—

	Yen.
Great Britain.....	531,017
America.....	2,153
Germany.....	66

Bicarbonate of soda comes from Great Britain to the value of 102,917 yen. So with quinine. Great Britain sends it to the value of 129,391 yen. The total value of carbolic acid imported amounts to 176,190 yen, chiefly from England. Bismuth subnitrate comes from Germany to the value of 108,459 yen. The total value of liquid gold amounts to 110,522 yen. This is chiefly from Great Britain.

#### AUSTRALIAN KIESELGUHR.

*Chem. and Druggist*, Nov. 13, 1897, 749.

Kieselguhr of varying quality is obtained at several places in Victoria, one of the best grades coming from Avoca. It is shipped to Britain and Germany. It has been recommended to the Queensland Railway Commissioners for packing strong acids, which the Queensland Government will not carry on the railway in small quantities by ordinary trains. The suggestion that kieselguhr should be used for absorbing acids, so that they could be carried without being packed in jars, has been tried, but has not been found to answer in practice. The acids absorb water from the atmosphere so rapidly that impregnated kieselguhr gets converted from an almost dry powder to a pulp.

#### PETROLEUM IN NEWFOUNDLAND.

*Imp. Inst. J.*, Nov. 1897, 338.

In a recent number of the *Imperial Institute Journal* (Vol. III., p. 154) a short account was given of the mineral

wealth of Newfoundland, in which it was stated that petroleum had been found on the west coast of the island, but no particulars were given of the extent and quality of the supply. The following details are furnished by an article in *The Canadian Engineer* for September (p. 125):—

The oil-producing district appears to extend over an area of about 250 square miles, and, in geological formation, consists of limestone, and conglomerates thereof, shales, and sandstones.

An analysis of the crude oil, gathered from surface depressions, gave the following results:—

	Per Cent.
Specific gravity.....	0.885
Water.....	Trace
Gasoline.....	None
Naphtha.....	0
Illuminating oil.....	14.5
Lubricating oil.....	82.5
Solid residue.....	3.0
Sulphur.....	0.068

The oil obtained from a depth of 1,000 ft. was, however, much lighter, and yielded a higher percentage of illuminating oil. The crude oil was dark olive green in colour, of aromatic odour, and had a specific gravity of 0.844 at 60° F. On distillation it yielded:—

	Per Cent.
Naphtha.....	7
Illuminating oil.....	56
Lubricating oil.....	34
Coke.....	3

The products of distillation have a pleasant odour and are very easy to refine. The illuminating oil is water-white, of high flashing point, and burns with a brilliant flame. The crude oil is very free from grit and other foreign substances, and, consequently, the heavy oil, after suitable treatment, makes a very good lubricant. The quality of the oil compares very favourably with the best American oils.

All the wells hitherto sunk belong, with one exception, to the Newfoundland Oil Company, with whom an English company is stated to be negotiating for the acquisition of the property. These wells are close to the sea, and only six to ten miles of pipe will be required to convey the oil to the water.

#### THE INDIAN CINCHONA PLANTATIONS.

*Imp. Inst. J.*, Nov. 1897, 338.

The reports of the Madras and Bengal Governments on their respective cinchona plantations have recently been issued. The salient features of these reports are mentioned in articles in the *Chemist and Druggist* (October 2nd, 1897), and the *Indian Pharmacologist* (September 1897). In the case of the Madras plantations, there has been an increase of 47,257 rupees over the officially estimated revenue of 100,000 rupees. This increase is said to be mainly due to improvements in the extraction of the alkaloid quinine, introduced by the superintendent, Mr. Standen, whereby the yield of sulphate of quinine has been increased from 1.5 per cent. to 3.3 per cent. The subjoined table shows the yield of cinchona products for the past five years:—

	1892-93.	1893-94.	1894-95.	1895-96.	1896-97.
	Lb.	Lb.	Lb.	Lb.	Lb.
Bark worked.....	171,717	175,000	196,000	323,800	238,100
Yield of quinine...	4,933	2,069	4,799	3,600	7,891
" febrifuge..	3,139	5,775	1,756	2,284	3,369
" total alkaloid.	8,072	7,775	6,526	5,884	11,241

The Indian Government does not compete in the matter of sale of bark in the European market; all that is produced is sold to the Indian Medical Stores, or to native customers; quinine at 18 rupees, and febrifuge at 16 rupees per lb. A considerable quantity, in packet form, is disposed of to the native populations, being thus sold by native postmasters, at 1 piece each packet. The amount distributed in this way in 1896 was 2,000 lb.

In the Bengal cinchona plantations, a similar progress is noted. The stock of febrifuge-yielding trees (red bark) is being gradually decreased in favour of quinine-yielding trees. There are now in the Bengal cinchona gardens, 2,683,451 trees, of which only 185,000 are febrifuge-yielding.

The year's crop of dry bark amounted to 679,222 lb., while the quinine produced was 10,672 lb., and febrifuge, 152 lb.

The net profit on the year's working was 9,767 rupees, against 4,598 rupees in the preceding year.

The amount of quinine sold in piece packets in this province during the year was 3,330 lb., an increase of 130 lb. over the previous year.

All restrictions on the sale of quinine to other governments and administrations have now been removed, and the superintendent has been instructed to comply with any demand he may receive.

#### INDIAN HEMP PRODUCTS.

*Imp. Inst. J., Nov. 1897, 337.*

In a "Supplementary Note" to the Excise Board of India recently made by Dr. Prain, of the Royal Botanic Gardens, Sitpur, Calcutta, some interesting information is given as to the method of storing hemp products in order to prevent the deterioration which always takes place after they have been kept for two or three years.

The various forms of Indian hemp are exciseable articles in India, and their storage in bond has occasionally been a source of loss to the Government.

It had already been suggested by Dr. Pain that storage in hermetically sealed tins might overcome the difficulty, but in an experimental batch so treated it was found that the water present in the hemp had produced fermentation, and the "ganja," as the pressed tops of the hemp plant are called, had developed "a strong rancid odour," and had become "quite unfit for smoking."

It has now been found that if the "ganja" be kept in dry deal perforated boxes, it can be stored for two or three years without fermenting or losing its narcotic properties, and Dr. Prain recommends this method of preservation to the Excise Board. Appended to this supplementary report is a translation of a paper by Mr. L. Lapin, of the Dorpat Pharmaceutical Institute, who has recently investigated the Indian hemp plant with a view to the isolation of the true active constituent. He has obtained a substance, called "Cannabindon" by him, which appears to have all the physiological properties of the plant. From the description of this substance given by Mr. Lapin, it seems to be identical with the "cannabinol" obtained by a much simpler process from "charas" (Indian hemp resin) by Messrs. Wood, Spivey, and Easterfield (*Imp. Inst. J.*, March 1897). It is very probable that the various substances which have from time to time been regarded as the active constituents of Indian hemp may have been merely impure specimens of "Cannabindon," and this is borne out by the fact that the various preparations of Indian hemp which have been generally regarded as physiologically active are either purified alcoholic or ethereal extracts of the drug, as the following tabular arrangement of the best known of these preparations shows:—

Name of Preparation.	Character of Preparation.	Name of Investigator.
Canada.....	Alcoholic extract of the previously purified drug.	Smith.
Canada.....	(Method of preparation not known.)	Merck.
Canada.....	Alcoholic extract of previously washed drug.	Decourtiere.
Canada.....	Purified alcoholic extract.	Fischer.
Canada.....	Method of preparation not known.	Merck.
Hemp (Indian hemp).....	Alcoholic extract purified by treatment with alkaline solutions.	..
Hemp (Indian hemp).....	Method of preparation not known.	Merck.
Hemp (Indian hemp).....	Purified ethereal extract.	Lapin.
Hemp (Indian hemp).....	Purified alcoholic extract.	..

Dr. Prain, however, regards it as unlikely that an extremely stable substance such as "cannabinol" should be the active constituent of a drug which so readily loses its physiological properties. The matter is one which still requires further investigation.

#### PRODUCTION OF QUICKSILVER IN RUSSIA.

*Eng. and Mining J., Oct. 23, 1897, 490.*

The production of quicksilver at the mines of A. Auerbach and Co., near the Nikitowka station (on the Kursk-Kharkov Railway) in the Bachmut district of the government of Ekaterinoslav, from the beginning has been as follows:—

Year.	Average Yield of Ore.	Production of Metal.	Year.	Average Yield of Ore.	Production of Metal.
	Per Cent.	Kilos.		Per Cent.	Kilos.
1887	1.00	64,062	1893	0.46	260,990
1888	0.76	164,815	1894	0.45	195,987
1889	0.51	167,169	1895	0.69	431,070
1890	0.75	212,137	1896	0.71	491,455
1891	0.80	328,865	1897	0.79	498,224
1892	0.65	342,768			

\* To Oct. 1st, 1897.

These are the only quicksilver mines in Russia. The metallurgical practice at the works, which employ the Auerbach improved Schernia furnaces, is very good, and ore yielding 0.4 per cent. of quicksilver is said to cover the cost of production.

#### THE NOTHBURG COKE-OVEN PLANT.

*Eng. and Mining J., Oct. 22, 1897, 484.*

On a visit by the members of the Aachen section of the Verein Deutscher Ingenieure to the Nothberg Colliery, owned by the Eischweiler Bergwerks Verein, Herr Welcke read a paper on the coke-oven plant of that colliery, observing that two years ago the company was induced to put up a bank of 60 ovens, with plant for recovering the by-products, on account of their affording the advantages which are thus summarised by the *Colliery Guardian*. (1.) Higher yield from the small coal charged in, with equal quality of coke, while the coking is effected with complete exclusion of air. (2.) Considerably higher output per oven, on account of the larger charge of small coal, from which the gases are soon driven off by uniform heating by means of gas from the outside; and (3.) Recovery of the valuable by-products ammonia, tar, and benzol, from the gases of the small coal. Against these advantages, however, must be mentioned the greater first cost and higher current expenses, with a smaller amount of heat available for firing the boilers, although the advantages predominate, so that by far the largest number of new ovens are arranged for by-product recovery. In the discussion which followed the reading of this paper, Herr Othberg stated the reasons why two different types of oven had been adopted at Nothberg. On the one hand, it was considered advisable, while recovering the by-products, to utilise the gases as far as possible for firing the boilers, and from this standpoint the Ruppert oven was preferred. On the other hand, however, the question arose of employing, in addition to the Nothberg bituminous coal, the non-bituminous of the Anna Colliery, and from the latter standpoint the Otto oven recommended itself, because permitting the use of coals containing little gas, as well as the recovery of the by-products.

#### THE SUPPLY OF ASBESTOS.

*Engineering; through Imp. Inst. J., Nov. 1897, 339.*

The French manufacturers of asbestos goods are supplied from four sources:—(1.) Canada, whence the asbestos is white, silky, very unctuous, having supple fibres from 5 to 25 mm. in length; of all varieties it is that which spins the most easily. (2.) Siberia, whence the mineral is yellowish, some species being of a straw yellow. The fibre is less flexible, and more woody, but stronger, than the Canadian,

which it resembles in length; large masses of long-fibre mineral being, however, rarer. (3.) The Cape of Good Hope asbestos has a characteristic blue colour. It occurs in larger masses than either the Canadian or Russian, and its fibre is generally longer and stronger. In spinning or other manipulation, however, it is difficult to handle, a good deal of the fibre being reduced to powder. (4.) In Italy there are different kinds of asbestos, but generally they are little adapted to spinning. There are some long silky fibres of little resistance, employed for gas furnaces; others are very short and fit only to make heat-retaining coverings.

#### PLATINUM IN ONTARIO.

*Eng. and Mining J., Oct. 23, 1897, 484.*

The *Canadian Mining Review* reports the discovery in this province of a deposit of sand carrying considerable quantities of platinum and an unusually large proportion of osmium and iridium.

#### ENGLISH ARSENIC.

*Chem. and Druggist, Nov. 6, 1897, 736.*

The output of arsenic in England is being gradually reduced as the quantity of tin diminishes. In Cornwall last year (1896) 1,366 tons of arsenious acid, or white oxide of arsenic, were produced, the value of which at the mines was estimated at 14,997*l.* Devonshire produced, in 1896, 2,250 tons of arsenic, the value being 30,486*l.* On the whole, therefore, the output has fallen from 1,798 tons, of the value of 52,198*l.*, last year, to 3,616 tons, value 15,483*l.*, this year. On the other hand, the quantity of arsenical pyrites extracted under the Metalliferous Minerals Act and sold for the manufacture of white arsenic has made an extraordinary leap. In 1895 only 2,951 tons of this mineral were sold in the two southern counties, fetching the sum of 2,785*l.* In 1896 the value of the 8,808 tons of pyrites was no less than 8,007*l.*, an increase in one year's output of 5,222*l.* With the exception of the three years 1883-85, however, the 1895 production was the smallest on record. Indeed, the outputs have varied enormously in different years. For instance, in 1891 the returns showed that 14,321 tons were extracted, and in 1892, 12,564 tons. This was followed by the production of under 2,000 tons in each of the subsequent three years.

### BOARD OF TRADE RETURNS.

#### SUMMARY OF IMPORTS.

Articles.	Month ending 31st October	
	1896.	1897.
	£	£
Metals.....	1,708,823	1,853,430
Chemicals and dyestuffs .....	444,570	329,470
Oils.....	700,394	735,969
Raw materials for non-textile industries.	4,541,091	5,241,185
Total value of all imports .....	39,574,890	38,943,763

#### SUMMARY OF EXPORTS.

Articles.	Month ending 31st October	
	1896.	1897.
	£	£
Metals (other than machinery) .....	3,139,132	3,653,570
Chemicals and medicines .....	651,412	708,606
Miscellaneous articles.....	3,166,584	2,409,626
Total value of all exports.....	20,683,157	19,283,602

#### IMPORTS OF METALS FOR MONTH ENDING 31st OCTOBER.

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

23,947. R. L. Walker. Improvements in refuse or garbage furnaces. Oct. 18.

24,014. P. E. M. Jamain. Improvements in apparatus for compressing powdered substances. Oct. 18.

24,041. R. G. Ferguson and A. M. Elkus. Improvements in apparatus for mixing liquids with gases. Complete Specification. Oct. 19.

24,084. G. Barker.—From L. Rissmuller, Germany. Centrifugal separators. Oct. 19.

24,201. J. Klein. Improvements in and connected with apparatus for the condensation of steam and vapours. Complete Specification. Oct. 20.

24,227. T. Christie. An apparatus for raising liquid. Oct. 20.

24,342. A. J. Bell and P. A. G. Bell. Improvements in apparatus for the filtration of water, sewage, and other fluids. Oct. 21.

24,698. M. Deville. Improved centrifugal apparatus for sorting or separating ores. Complete Specification. Oct. 25.

24,922. G. T. Tugwell. Improvements in apparatus for the production of hydrogen gas. Oct. 27.

21,933. H. H. Lake.—From O. Brzostowicz, Belgium, and R. Nitzsche, Germany. Improvements in carburising apparatus. Oct. 27.

25,084. G. Hawkins, H. Hawkins, and S. H. Hawkins. A new or improved hydrogen gas generator. Oct. 29.

25,265. G. Helps. Improvements in and relating to regenerative furnaces for the heating of gas retorts and the like. Nov. 1.

25,379. G. A. Nussbaum. Improvements in devices for absorbing, dispensing, or conducting heat, applicable also for separating and superheating steam. Nov. 2.

25,511. D. Black. Improvements in filter presses and similar filtering apparatus. Nov. 4.

25,634. E. Theisen. Process and apparatus for absorbing, extracting, distilling, or evaporating liquids and gases or vapours. Nov. 4.

25,654. The Reeves Patent Filters Company, Ltd., and W. Reeves. Improvements in or connected with filtering apparatus. Nov. 4.

25,793. C. Delecroix. New or improved hamper for bottles containing acids, essences, and the like. Nov. 6.

25,867. E. T. Bousfield. Improvements in vaporisers. Nov. 6.

25,898. E. Beekton. A portable spout to attach to drums containing ammonia or other strong or obnoxious chemicals. Nov. 8.

26,002. G. Watson. Improvements in furnaces for the destruction of town refuse. Nov. 9.

26,151. H. A. House, jun., and R. R. Symon. Improvements in apparatus for regulating the supply of combustible liquid or vapour to liquid fuel burners. Nov. 12.

26,525. J. T. Bentley. Improvements in apparatus for cooling liquids. Nov. 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.\*

1896.

27,009. P. H. Rosenkranz. Diaphragms. Oct. 27.

28,289. S. Sherratt and W. A. Richards. Method and apparatus for filtering, washing, and drying crystalline, granular, and other materials. Nov. 3.

29,000. P. J. E. E. Chambost. Apparatus for heating or evaporating by means of hydrocarbon liquids of any density. Nov. 3.

29,318. W. Stagg, R. T. Glover, and J. G. Glover. Pressure or vacuum gauges. Nov. 27.

1897.

3,219. G. Zschocke. Hurdles or grids for gas purifiers and cooling, drying, and graduating apparatus. Nov. 3.

17,099. C. H. Pieper and A. F. Pieper. Rheostats. Oct. 27.

#### II.—FUEL, GAS, AND LIGHT.

##### APPLICATIONS.

23,977. W. Johnson. Improvements on apparatus for the production and use of acetylene gas. Oct. 18.

24,292. A. J. Boulton. From L. Meneveaux, France. Improvements in or relating to apparatus for the manufacture of acetylene gas. Oct. 20.

24,301. J. McConechy. Improvements in apparatus for the production of acetylene gas. Oct. 21.

24,328. J. Wilson. Improvements in and in the manufacture of burners for incandescent gas lighting. Oct. 21.

24,435. H. A. Kent. Apparatus for the production of hydrogen gas and air. Oct. 22.

24,488. R. Schlatter. Improvement in acetylene gas generators. Oct. 22.

24,602. G. Mabeke and C. Kraft. An improved means of protection of incandescent gas light mantles. Complete Specification. Oct. 23.

24,611. A. Coze. Improvements in apparatus for charging inclined gas retorts. Oct. 23.

24,707. C. Guy. Improvements in apparatus for the production of acetylene gas. Oct. 25.

24,815. H. Ottenbruch. Improvements in mantles for incandescence gas lighting. Complete Specification. Oct. 26.

24,816. G. Fürbringer. Improvements in apparatus for generating acetylene gas. Oct. 26.

24,822. A. Syssoyeff and L. Braly. Improvements in auto-luminous compositions. Complete Specification. Oct. 26.

24,860. H. Wilson and T. Mitchell. Improvements in or relating to the generation of acetylene and other gases. Oct. 27.

25,002. L. de Ravel. Improvements in apparatus for the production of acetylene gas. Oct. 28.

25,023. W. B. Hartridge. Apparatus for manufacturing perforated fuel blocks. Oct. 28.

25,287. R. Farrington and M. H. Hawes. Improvements in and relating to incandescent gas lighting. Nov. 1.

25,318. J. W. Grainger. Improvements in and relating to the manufacture of fire-lighters. Nov. 1.

25,623. F. J. J. Bagley. Improvements in the manufacture of fire-lighters and fuel. Nov. 4.

25,627. W. R. Bell. An improved method or process and apparatus for the preparation of peat for fuel. Nov. 4.

25,632. R. E. Perraga. Improvements in method and apparatus for generating formaldehyde gas. Complete Specification. Nov. 4.

25,674. S. T. White. See Class XI.

25,750. J. Zimmerman. Improvements in gas-producing materials. Complete Specification. Nov. 5.

25,800. J. W. Searth and W. A. Thoratou. Improvements in or relating to lamps for burning acetylene gas. Nov. 6.

25,801. J. W. Searth and W. A. Thoratou. Improved apparatus for the generation of acetylene gas and like purposes. Nov. 6.

25,853. C. J. Landstrom. Improvements relating to apparatus for developing acetylene gas. Nov. 6. Date applied for Aug. 6, 1897, being date of application in Sweden.

25,866. A. H. Poppel. Improvements in apparatus for the manufacture of gas. Nov. 6.

25,870. A. H. Barthez. Improvements in apparatus for the automatic production of acetylene gas. Nov. 6.

25,949. C. Duval. Improvements in apparatus for generating acetylene gas. Nov. 8.

25,952. The Acetylene Light Syndicate, Ltd., and J. Gore. Improvements in apparatus for the manufacture of acetylene gas. Nov. 8.

26,095. M. Letay. Improvements in or relating to apparatus for use in the production of acetylene or similarly produced gas. Filed Nov. 9. Date applied for April 14, 1897, being date of application in France.

26,202. A. Martini. Improvements in and relating to incandescent mantles. Nov. 10.

26,269. G. E. Arkell, J. W. Bailey, and J. Clapham. Improved apparatus for use in the production of acetylene. Nov. 11.

26,311. J. Janz. Improvements in the manufacture of fabrics for incandescence mantles for illuminating purposes. Complete Specification. Nov. 11.

26,325. A. J. Boulton. From F. Alexandre, France. Improvements in or relating to apparatus for the manufacture and use of acetylene gas. Nov. 11.

26,381. A. M. Plaissetty. New incandescent mantle by gas, mineral oils, alcohol, and process of fabrication related thereto. Nov. 12.

26,435. J. Mücke and J. Mücke. Improved apparatus for generating acetylene gas. Complete Specification. Nov. 12.

26,484. C. A. Miller and F. J. Miller. Improvements in acetylene gas generating apparatus, principally for use in connection with cycle lamps and other lighting appliances generally. Nov. 13.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

26,191. E. T. Zohrab. Production of peat charcoal and apparatus therefor. Oct. 27.

27,212. J. Wetter. From G. Meyer. Apparatus for generating acetylene gas. Nov. 3.

28,101. J. A. Sinclair. Means for lighting by electricity and incandescence. Nov. 3.

28,206. T. R. Fowler. Acetylene gas generator, purifier, and container. Nov. 17.

29,168. E. Richard-Lagerie. Apparatus for producing acetylene gas. Oct. 27.

29,597. A. Bandsept. Incandescent burners. Oct. 27.

29,603. J. Spurge. Gas-cleansing apparatus. Nov. 3.

29,763. W. H. Dargue. Apparatus for the production, drying, purifying, and storage of acetylene gas. Nov. 3.

1897.

501. R. Langhans. Manufacture of incandescing media for use in incandescent gas lighting. Nov. 17.

512. G. Lebrun and F. Cornaille. Apparatus for producing acetylene gas. Nov. 10.

3013. W. P. Thompson. From P. P. H. Mace and L. L. H. Gerard. Apparatus for the production of acetylene gas. Oct. 27.

3667. H. A. Kent. Inverted regenerated incandescent gas burners or lights. Nov. 17.

11,739. F. R. Foster. Incandescent mantles for gas-burners. Nov. 17.

\* See Note (\*) on previous page.

14,090. E. Jimeno. Apparatus for the production of acetylene. Nov. 10.

19,411. H. J. Bell and The Niagara Falls Acetylene Gas Machine Company, Ltd. Apparatus for production and storage of acetylene gas. Nov. 3.

20,464. A. Chauvel and G. Ménétrier. Manufacture of fuel cakes or blocks for industrial and domestic purposes. Nov. 3.

21,831. H. H. Lake.—From The Wizard Manufacturing Company, United States. Production of acetylene gas, and lamps for generating and burning the same. Oct. 27.

22,120. G. Hilgenstock. Improvements in coke ovens. Nov. 17.

22,730. A. Flock. Apparatus for producing acetylene gas. Nov. 17.

23,198. F. Bosshardt.—From A. Molet, Argentine Republic. Automatic apparatus entitled "spirit," for the production of acetylene gas. Nov. 17.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

#### APPLICATIONS.

25,501. T. F. Haldane. Improvements in obtaining products in distilling wood. Nov. 3.

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

24,287. J. C. Mewburn.—From Chemische Fabrik von Heyden-Gesellschaft mit beschränkter Haftung, Germany. Production of oxyphenyl-guanidines and their derivatives. Oct. 20.

24,410. C. D. Abel.—From The Actien-Gesellschaft für Anilin-Fabrikation, Germany. The manufacture of new colouring matters of the safranine series. Oct. 21.

24,527. C. D. Abel.—From The Actien-Gesellschaft für Anilin-Fabrikation, Germany. Manufacture of black diazo-colouring matters. Oct. 22.

24,644. C. E. Gassmann. A process for obtaining new mordant dyes. Oct. 25.

24,704. A. H. Goldberg, W. Siepermann, and H. Flemming. A process for the production of canarine. Oct. 25.

24,793. J. C. Mewburn.—From Chemische Fabrik von Heyden-Gesellschaft mit beschränkter Haftung, Germany. Improvements in the production of phenolic carbonates. Oct. 26.

24,938. S. Pitt.—From L. Cassella and Co., Germany. Producing dyestuffs from amidophenols. Oct. 27.

24,964. I. Levinstein and Levinstein, Ltd. Production of colouring matters from tetrazo compounds of dichlorbenzidine. Oct. 28.

25,136. S. Pitt.—From L. Cassella and Co., Germany. Producing diamido-oxydiphenyl and like bases. Oct. 29.

25,234. S. Pitt.—From L. Cassella and Co., Germany. Production of direct-dyeing black cotton dye-stuff. Oct. 30.

25,332. S. M. Angel. Improved dye for textile fabrics, feathers, and the like. Nov. 1.

25,500. W. E. Heys.—From A. Liebmann, Germany. The production of colouring matters on vegetable fibres. Nov. 4.

25,756. O. Imray.—From The Fabriques de Produits Chimiques de Thann et Mulhouse, Alsace. Manufacture of para- and meta-nitroanisidine, and of colouring matters therefrom. Nov. 5.

25,787. A. Bang.—From G. A. Dahl, Germany. The production of direct-dyeing blue dye-stuffs. Nov. 6.

26,419. C. D. Abel.—From The Actien-Gesellschaft für Anilin-Fabrikation, Germany. The manufacture of mordant-dyeing diazo colouring matters. Nov. 12.

26,471. I. Levinstein and Levinstein, Ltd. Production of new sulphonic acids. Nov. 12.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

23,551. T. A. Myers. Manufacture and packing of blue for laundry purposes, liquid dyes, and other liquids. Oct. 27.

29,706. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünning. Manufacture of dyestuffs of the series known as patent blue. Oct. 27.

29,827. P. A. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Production of dyestuffs on fibre. Nov. 3.

29,828. S. Pitt.—From L. Cassella and Co. Production of a brown colouring matter. Nov. 3.

1897.

765. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of colouring matters and of new intermediate products. Nov. 17.

1320. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünning. Manufacture of alpha-naphthylamine in an easily diazotisable and stable form. Nov. 17.

10,810. J. Hauff. Preparation of orthotoluolsulpho acid and of orthosulpho benzoic acid by oxidation of orthothioresc. Nov. 10.

19,783. R. Webb. Security inks. Nov. 10.

### V.—TEXTILES, COTTON, WOOL, SILK, Etc.

#### APPLICATIONS.

24,028. W. G. Heys.—From H. David, France. Improvements in and connected with the treatment of vegetable textile fabrics and materials with mercerising solutions. Oct. 19.

24,468. G. Ormondroyd. Improvements in the method of and apparatus for scouring hanks of yarn. Oct. 22.

24,528. C. Wetherwax. An improved process of treating flax and hemp for obtaining textile fibres therefrom. Oct. 22.

25,468. W. P. Ingham. Improvements in or connected with the manufacture of slag wool. Nov. 3.

25,944. A. J. Boulton.—From J. Buffard, France. Improved process and composition for rendering fabrics waterproof. Nov. 9.

26,120. T. C. Taylor and J. E. Tolson. Improvements in apparatus to be employed in carbonising, neutralising, and bleaching fabrics and fibres. Nov. 10.

26,247. W. G. Heys.—From H. David, France. Improvements in and connected with the production of lustrous effects upon vegetable textile materials. Nov. 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

25,362. V. Bona. Manufacture of textile fabrics. Oct. 27.

26,485. J. S. Brown. Process and apparatus for preparing vegetable fibres for textile purposes. Oct. 27.

27,484. H. C. Longsdon. Means or apparatus applicable for use in the drying of wool and other fibrous substances. Oct. 27.

28,613. D. M. Sutherland and W. McLaren. Treating nitro-cellulose for the purpose of coating or impregnating textile and other fabrics. Nov. 3.

29,832. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünning. See Class VI.

1897.

12,541. C. L. Bachelier. Treatment of textile plants to remove the fibre therefrom. Nov. 3.

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

#### APPLICATIONS.

24,506. S. Musgrave, H. Musgrave, and J. T. Musgrave. An improved method of and process for obtaining iridescent colours upon paper or other suitable material. Oct. 22.

24,533. C. L. Horack. Method of and apparatus for colouring yarns. Oct. 22. Date applied for April 13, 1897, being date of application in United States.

24,868. J. Stockhausen. See Class XII.

25,117. E. Lehmann. An improved process for marbling, mottling, or colouring paper or cardboard on one side in the paper machine. Complete Specification. Oct. 29.

25,162. H. R. Cassel. An improved method or process of bleaching pulp fibres, textile fabrics, and other materials. Oct. 30.

25,542. W. Shedlock. Improvements relating to the bleaching, drying, dyeing, and washing of textile materials and to apparatus therefor. Nov. 3.

25,564. W. H. Thorpe. Improvements in machinery for dyeing, scouring, and bleaching hanks or skeins of yarn. Nov. 4.

25,590. W. E. Heys.—From A. Liebmam, Germany. See Class IV.

25,598. H. J. McBride, H. W. McBride, and F. Duffin. Improvements in the process of bleaching linen union or cotton fabrics. Nov. 4.

26,538. A. C. Marot and A. Bonnet. An improved process for mordanting cotton for aniline black. Nov. 13.

#### COMPLETE SPECIFICATIONS ACCEPTED. 1896.

25,581. E. J. Stewart. Improvements in dyeing. Oct. 27.  
27,409. A. Leven. Process for dyeing a thread in different colours. Nov. 17.

29,150. F. A. Gatty and Co., Ltd., and V. H. Gatty. Dyeing wool or other animal fibres in either the raw or manufactured state.

29,832. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Production of local, durable silk-like gloss effects on cotton or linen stuffs by means of printing. Nov. 3.

1897.

13,088. H. Zublin and A. Zuigg. White and colour discharge on enlavage printing of dyed para-nitraniline red and related substances. Oct. 27.

19,005. H. Seidel. Mordanting of fibrous materials preparatory to dyeing such materials. Oct. 27.

#### VII.—ACIDS, ALKALIS, AND SALTS. APPLICATIONS.

23,916. W. Galbraith. The extraction or recovery of potash and soda salts, and of iodides and bromides from the waste liquors resulting from the extraction of ammonia from blast-furnace gases. Oct. 18.

24,077. A. J. Boulton.—From R. Memmo, Italy. Improved manufacture of calcium and other carbides and by-products obtained thereby. Oct. 19.

24,515. C. C. Moore. Improvements in the treatment or purification of brine and other saline solutions. Oct. 22.

24,524. A. MacNab.—From W. A. Willock, India. An improvement in the manufacture of bay salt. Complete Specification. Oct. 22.

24,525. O. Imray.—From W. T. Gibbs, Canada. Improvements in the manufacture of potash salts. Oct. 22.

25,007. H. S. Elworthy. An improved process for the manufacture of carbonic acid and apparatus therefor. Oct. 28.

25,042. E. M. Taylor. Alkali phenate compound for bleaching, scouring, and stripping. Oct. 29.

26,172. M. Goldschmidt. An improved method or process of preparing oxalic acid and oxalates. Nov. 10.

26,176. J. C. Mewburn.—From Chemische Fabrik von Heyden Gesellschaft mit beschränkter Haftung, Germany. Improvements in the production of halogen compounds of silver. Nov. 10.

26,326. D. Lauce and R. L. E. de Bourgade. A process for the economic production of cyanides, their derivatives, and other nitrogen compounds. Complete Specification. Filed Nov. 11. Date applied for April 12, 1897, being date of application in France.

#### COMPLETE SPECIFICATIONS ACCEPTED. 1896.

24,573. C. Hoepfner. Production of chloride of zinc and chlorine. Nov. 10.

28,891. G. Kynoch and Co., Ltd., and A. T. Cocking. Purifying and concentrating sulphuric acid in part applicable to the manufacture of nitric acid. Nov. 3.

1897.

381. A. K. McCosh. See Class X.

591. P. J. Worsley and the United Alkali Co., Ltd. Manufacture of caustic soda or caustic potash from carbonate of soda or carbonate of potash. Nov. 10.

17,313. H. J. Krebs. Process and apparatus for distilling ammonia. Nov. 17.

#### VIII.—GLASS, POTTERY, AND ENAMELS.

##### APPLICATIONS.

23,933. W. Burton and J. Burton. Improvements in the construction of potters' kilns. Complete Specification. Oct. 18.

24,015. A. J. Boulton.—From A. Panigatti, A. Merenda, and F. Passadero, Italy. Improvements in or relating to the ornamentation of glass. Oct. 18.

24,278. G. L. Siever. Improved process and apparatus for the manufacture of ceramic panels for decorative purposes. Oct. 20.

24,317. B. Swinden. Improved method of and composition for polishing glass. Complete Specification. Oct. 21.

24,505. A. C. Tulloch. Improved method of and means for the drying of china clay. Oct. 22.

24,729. The Chromo-Transfer Company, Ltd., and H. Wallace. An improvement in the decoration of pottery, china, and the like. Oct. 26.

26,384. F. Hancock and C. B. Winzer. Improvements in or applicable to kilns or mufles used for pottery and brick purposes. Nov. 12.

26,401. J. Davis, A. J. Davis, and A. J. Loftus. Improvements in the manufacture of lenses and other articles of ruby-coloured glass, and in appliances to be used in the said manufacture. Nov. 12.

26,446. J. Clowes, T. Poole, and A. J. Poole. Improvements in kilns for firing pottery and other goods. Nov. 12.

26,537. A. Macaire and C. Senero. An improved process of and apparatus for printing on brittle surfaces, such as glass, crystal, porcelain, and the like. Complete Specification. Nov. 13.

#### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

##### APPLICATIONS.

23,993. C. G. J. Frosell. An improved composition applicable for cement, artificial stone, and the like. Oct. 18.

24,179. C. E. Lee and C. F. Lawton. Improvements in the manufacture of cement. Oct. 19.

24,409. L. Brockmann. Improvements in the production of artificial stone. Oct. 23.

24,928. G. E. Gray and T. W. Pallin. An improved process for producing imitations of marble, granite, or other ornamental stones. Oct. 27.

25,685. A. Küpper. Improvements in manufacturing hollow building blocks or artificial stones, and in apparatus employed in their manufacture. Nov. 5.

25,861. D. H. Ferguson. Improvements in material for the construction and decoration of buildings. Complete Specification. Nov. 6.

26,243. L. Tebbutt. Improved removable floor for cement and other kilns. Nov. 11.

26,334. H. H. Lake.—From O. Leproux, France. An improved composition for preserving wood. Nov. 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

25,292. C. Craig and G. K. Craig. Building blocks and method of using same. Oct. 27.

26,306. G. Scott. Concrete building construction. Nov. 3.

27,975. S. R. Thompson. Composition or cement for making pipe and other joints. Oct. 27.

1897.

13,821. G. F. Lebolda. Apparatus for drying and hardening wood. Nov. 17.

#### X.—METALLURGY, MINING, ETC.

##### APPLICATIONS.

23,921. A. Gutensohn. Improved process for separating gold and other precious metals from pyritic auriferous ores and the like. Oct. 18.

24,121. W. P. Thompson.—From E. C. Ketchum, United States. Improved process for treating mixed sulphide ores. Complete Specification. Oct. 19.

24,267. P. E. Secrétan. A new or improved alloy of aluminium, and process for making the same. Oct. 20.  
 24,126. W. L. Wise.—From J. W. Comley, United States. Process and apparatus for welding metals. Oct. 21.

24,490. S. H. Byass. Improved means for facilitating the annealing of metal sheets. Oct. 22.

24,526. O. Imray.—From W. T. Gibbs, Canada. Treatment of zinc ores. Oct. 22.

24,696. B. Mohr. An improvement in the treatment of sulphide ores for separation of zinc therefrom. Oct. 25.

24,875. Sir T. G. F. Hesketh, Baronet. The hardening of copper and other metals by the action of a chemical agent. Oct. 25.

25,080. R. Wootton and G. B. Martin. Improvements in the mode and means for annealing metal. Oct. 29.

25,929. Sir T. G. F. Hesketh. A new method of hardening metals. Nov. 8.

25,930. W. L. Wise.—From J. W. Comley, United States. Process and apparatus for welding metals. Complete Specification. Nov. 9.

26,046. S. Guélin. Method of treating lead sulphide ores. Complete Specification. Nov. 9.

26,063. A. Reynolds. An improvement in the manufacture of crucible steel. Nov. 9.

26,196. La Compagnie de Métallurgie Générale (Société Anonyme). Process of preparation and treatment of ores other than iron ores. Complete Specification. Filed Nov. 10. Date applied for Aug. 23, 1897, being date of application in Belgium.

26,290. R. Miller and J. Miller. Improvements in and relating to the manufacture of iron. Nov. 11.

26,406. C. H. Alldred. Improvements in the purification of iron and steel. Nov. 12.

#### COMPLETE SPECIFICATIONS ACCEPTED. 1896.

22,361. J. Armstrong. Extraction of lead, zinc, gold, silver, and other metals from sulphides, refractory or other ores or mattes. Nov. 19.

25,738. C. Hornung. Charging apparatus of blast furnaces. Nov. 3.

26,493. T. B. McGhie and E. G. Ballard. Beds or tests of cupellation furnaces, assay cupels, and the like. Oct. 27.

29,251. R. D. Barrie, and W. T. Lougher. Covering or coating steel and iron with copper or alloy of copper. Nov. 17.

29,709. W. Kirkham. Crucible melting furnaces. Nov. 3.

30,977. J. Burgess and W. A. Brodie. Producing castings in malleable iron, mild steel, and other metals. Nov. 17.

1897.

381. A. K. McCosh. Obtaining cyanides and other products from blast furnaces. Nov. 10.

11,438. W. G. M. Foote. Method of and apparatus for extracting metals from their ores or other compound bodies. Oct. 27.

16,898. F. Eller-hausen. Treatment of complex sulphide ores and apparatus therefor. Nov. 3.

18,731. F. George. Process of soldering aluminium. Nov. 10.

19,180. E. H. T. Plant and S. Dellow. Amalgamating pan. Oct. 27.

#### XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

##### APPLICATIONS.

21,951. R. Fabian. Improvements in electrodes for primary and secondary batteries in chemical cells. Oct. 19.

24,159. H. S. Lloyd. Improvements in electrodes for storage batteries. Complete Specification. Oct. 19.

24,257. F. O. Prince. Improvements in and connected with electric primary batteries. Oct. 20.

24,591. A. Heil. Improvements in galvanic cells. Oct. 23.

24,665. H. Wiggin and Co., Ltd., and G. A. Boeddicker. Improvements in anodes and in the electro-deposition of nickel and other metals. Oct. 25.

24,884. A. F. Harris. Improvements in electro-deposition apparatus. Oct. 27.

24,925. E. Giglio. Improvements in primary batteries. Oct. 27.

25,246. H. von der Linde. A process for the electrolytic separation of metals. Oct. 30.

25,386. H. K. Hess. Improvements in chemical electric generators. Complete Specification. Nov. 2.

25,388. L. Parvillée. Improved compositions for use in the construction of electrical heating apparatus and resistances and the processes for their manufacture. Complete Specification. Nov. 2.

25,400. E. Motz and H. F. Welch. Improved electrolytic process and apparatus for the separation of metals from their ores and solutions. Complete Specification. Nov. 2.

25,441. H. H. Lake.—From G. De Digoine, France. Improvements in electric accumulators. Nov. 2.

25,480. A. Graemiger. Improvements in electric accumulators. Nov. 3.

25,519. J. Hargreaves. Improvements in electrodes. Nov. 3.

25,674. S. T. White. Generation of electricity at gas works by utilising waste gases. Nov. 5.

25,703. W. W. Hanscom and A. Hough. Improvements in electrical batteries. Complete Specification. Nov. 5.

25,757. O. Imray.—From La Société Anonyme pour le Travail Electrique des Metaux, France. Improved manufacture of electrodes for electrical accumulator or secondary batteries. Nov. 5.

25,889. F. C. Geary and J. H. Rowbottom. An improved cell or box suitable for accumulator or other electric batteries. Nov. 8.

25,890. G. Bell and G. W. Bell. Improvements in or connected with electrolytic cells. Nov. 8.

26,067. F. E. Elmore.—Partly communicated by J. O. S. Elmore, India. Improvements in electrolytical apparatus. Nov. 9.

26,097. R. J. Crowley, C. E. Monkhouse, and A. Smith. Improvements in or relating to galvanic batteries. Nov. 9.

26,441. C. A. Bennett. Improvements in the preparation of accumulator plates. Complete Specification. Nov. 12.

26,543. F. E. Elmore.—Partly by J. O. S. Elmore, India. Improvements in apparatus for the generation and electrolytic application of electric currents. Nov. 13.

#### COMPLETE SPECIFICATIONS ACCEPTED. 1896.

25,701. J. H. May and F. King. Secondary batteries. Nov. 17.

26,059. C. C. Connor. Electrodes. Nov. 17.

27,167. C. E. O. Keenan. Electrical batteries. Nov. 10.

28,314. R. Kennedy. Electrical storage batteries and cells. Nov. 17.

28,511. L. Lucas. Manufacture of electric accumulators or secondary batteries. Oct. 27.

28,764. F. Hürter, and the United Alkali Co., Ltd. Apparatus for use in electrolysis, more especially intended for use in the electrolysis of zinc chloride. Nov. 3.

29,115. F. King. Electric storage or secondary batteries. Oct. 27.

1897.

425. F. King. Secondary batteries. Nov. 17.

10,439. C. E. Lee. Secondary batteries. Oct. 27.

18,430. F. Pescetto. Manufacture of electric accumulators. Nov. 10.

22,044. R. W. James.—From The Bell Electric Company, United States. Electric batteries, electrodes, and method of making same. Nov. 17.

22,045. R. W. James.—From The Bell Electric Company, United States. Electric batteries. Nov. 17.

## XII.—FATS, OILS, AND SOAP.

## APPLICATIONS.

- 21,217. J. Peacock. Improved manufacture or production of soap. Oct. 20.  
 24,438. W. J. Engleduc. Improvements in purifying and clarifying oils. Oct. 22.  
 21,773. E. Wilezynski. The manufacture of an improved soap. Oct. 26.  
 24,779. G. H. Evans. Combined Soap. Complete Specification. Oct. 26.  
 24,868. J. Stockhausen. Improvements in the manufacture of soap for use in dyeing and finishing textile fabrics and materials, and for other purposes. Complete Specification. Oct. 27.  
 25,505. H. Harris and H. Harris, Sons, and Co., Ltd. Improvements in the manufacture of soap tablets. Complete Specification. Nov. 3.  
 25,570. J. Schaschl and H. Hinterberger. Apparatus for purifying oily fluids and from separating the water therefrom. Nov. 4.  
 26,137. W. E. Woollyer. Improvements in and relating to soap. Nov. 10.  
 26,191. C. Culmann. An improved process for deodorising oils and fatty substances. Complete Specification. Nov. 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

- 26,396. R. Gesell. Process for making soap. Nov. 17.  
 27,906. F. W. Wright and The United Alkali Company, Ltd. Manufacture and production of dry soap or soap powder. Oct. 27.

## XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, ETC.

## APPLICATIONS.

- 23,957. F. J. Bergmann. Process for the production of graphite. Complete Specification. Oct. 18.  
 24,178. C. E. Lee, C. F. Lawton, A. L. Lawton, and A. W. Lawton. Improvements in the manufacture of paint. Oct. 19.  
 24,504. A. Stoop. An improved process for the manufacture of paints and pigments. Complete Specification. Oct. 22.  
 26,065. A. J. Smith. Improvements in the manufacture of varnish. Nov. 9.  
 26,107. H. Markus and G. B. Behrens, of the firm of D. Lee and Co. Improvements in and in the manufacture of india-rubber and gutta-percha. Complete Specification. Nov. 10.  
 26,268. W. N. Hird. Improved fire-resisting paint. Nov. 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1897.

- 18,533. D. J. Ogilvy. Method of making printing inks. Oct. 27.  
 20,902. W. Walters and A. Webb. Patent leather harness enamel. Oct. 27.

## XIV.—TANNING, LEATHER, GLUE, AND SIZE.

## APPLICATIONS.

- 24,080. A. J. Boulton.—From G. Brigalant, France. Improvements in or relating to the treatment of leather waste and in apparatus employed therein. Complete Specification. Oct. 19.  
 24,083. A. J. Boulton.—From G. Brigalant, France. Improvements in or relating to the manufacture of boards, plates, or sheets from leather pulp. Complete Specification. Oct. 19.  
 24,294. A. S. Bury and T. A. Brown. Improvements in machines for mixing and agitating size. Oct. 20.  
 25,008. H. Streich. Improvements in the preparation of leather. Complete Specification. Oct. 28.  
 25,324. P. Leyendecker. An improved machine for treating skins and hides. Nov. 1.  
 25,670. W. E. Walker and J. Longshaw. Improvements in and connected with tanning, and allied processes. Nov. 5.

25,871. H. H. Lake.—From C. Dreher, Germany. A process for waterproofing leather and rendering the same impervious to aqueous solutions. Nov. 6.

26,077. J. Birtwistle. Improvements in tanning. Nov. 9.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

23,742. J. T. Metquinn. Tanning hides, skins, and the like. Nov. 3.

1897.

20,125. J. Mossop, jun., and E. B. Garland. Tanning hides and skins. Oct. 27.

21,601. E. H. Dewson. Tanning of hides and skins and the like, and apparatus employed therein.

## XVI.—SUGARS, STARCHES, GUMS, ETC.

## APPLICATIONS.

- 24,333. H. Machin, of the firm of Batger and Co.—From E. A. Dex, Russia. Improvements in or relating to the manufacture of sugar and in apparatus therefor. Oct. 21.  
 24,593. D. Loiseau. Improvements in the processes of purifying and clarifying sugary products in sugar-houses, sugar, and molasses refineries, refineries, or factories of glucose and the like. Oct. 23.  
 25,752. A. Classen. Process for obtaining dextrin from starch and from formalindextrin. Nov. 5.  
 25,753. A. Classen. Process for obtaining directly from starch a compound of formaldehyde with dextrin soluble in water. Nov. 5.  
 25,860. M. Sachs. Improvements in crystallising vessels for crystallising sugar. Nov. 6.  
 26,418. A. Classen. Manufacture of albuminous substance soluble in water and processes therefor. Nov. 12.

## XVII.—BREWING, WINES, SPIRITS, ETC.

## APPLICATIONS.

- 28,938. J. Boulton, J. F. Jackson, and J. Ward. An improved process for the distillation of alcoholic spirits. Oct. 18.  
 25,020. J. Blauenfeldt and H. Tvede. A process for drying and preserving yeast. Oct. 28.  
 25,140. C. Ameye. A process and apparatus for sterilising and saturating with carbonic acid gas liquids contained in casks or like vessels. Complete Specification. Oct. 29.  
 25,996. B. J. Atterbury. Improvement in the production of alcohols. Nov. 9.  
 26,106. L. P. Ford. Improvements in apparatus for brewing. Nov. 10.  
 26,520. G. Delory. Improvements in the manufacture of beer. Complete Specification. Nov. 13.  
 26,532. J. F. H. Gronwald. Improvements in and relating to preserving beer. Nov. 13.

## COMPLETE SPECIFICATIONS ACCEPTED.

1897.

15,200. A. Fraser and MacLay and Co., Ltd. Manufacture of pale ale. Oct. 27.

18,713. D. J. Etty and C. R. Long. Process of and apparatus for ageing whisky. Oct. 27.

23,249. J. D. Moller. Improving or oxidising alcoholic beverages. Nov. 17.

## XVIII.—FOODS, SANITATION, ETC., AND DISINFECTANTS.

## APPLICATIONS.

## A.—Foods.

- 24,172. The Aerating Citroid Syndicate, Ltd., and G. Bamberg. Improved process of preparing soluble food in solid form. Oct. 19.  
 25,153. A. T. Perkins. Improvements in process and apparatus for the conservation of fruit and other perishable products. Complete Specification. Oct. 29.  
 26,292. R. R. Bell and A. C. Butler. Improvements in and relating to tea essences. Nov. 11.

*B.—Sanitation.*

23,913. J. Rudman and H. J. G. Rudman. New or improved process for the effective removal of noxious and other vapours, and appliances for use in connection therewith. Oct. 18.

25,259. J. Grossman. Improved method of treating sewage. Nov. 1.

26,069. G. E. Gale. System of apparatus for treating garbage. Nov. 9.

*C.—Disinfectants.*

26,250. J. H. G. Winckler.—From G. A. Spranger, Germany. An improved proceeding for making antiseptic ozone preparations. Nov. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

*A.—Foods.*

1897.

20,013. E. G. N. Salenius. Method and apparatus for sterilising milk and other liquids. Oct. 27.

*B.—Sanitation.*

1896.

24,833. B. Walker. The Walker process for treating sewage sludge. Nov. 3.

*C.—Disinfectants.*

1896.

29,288. W. B. Bottomley. Material for use in the treatment and purification of sewage and other impure waters. Nov. 3.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATION.

24,560. F. Cox, F. Kornacher, and M. Brumm. An improved writing paper, and ink therefor. Complete Specification. Oct. 23.

COMPLETE SPECIFICATION ACCEPTED.

1896.

26,045. C. Marter. Artificial ivory. Oct. 27.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

24,704. A. H. Goldberg, W. Siepermann, and H. Fleming. A process for the production of canarine. Oct. 25.

21,891. E. C. C. Stanford. An improved process for separating and obtaining the active constituents of the thyroid gland of the sheep and other animals. Oct. 27.

25,942. A. Classen. Manufacture of formaldehyde compounds of the protein bodies soluble in water. Nov. 8.

25,945. W. P. Thompson.—From J. Brissonnet, France. Improved creosote compound. Complete Specification. Nov. 8.

26,303. E. J. Boake. An improvement in the treatment of essences, liquid drugs, and the like for facilitating their transport. Nov. 11.

26,442. W. G. Whiffen. Improvements in the preparation of a crystalline compound of emetine. Nov. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

25,778. H. Helbing. Preparation and application of menthol. Oct. 27.

29,446. O. Imray.—From H. Hoffmann, La Roche and Co. Production of certain organic therapeutic preparations. Nov. 3.

1897.

656. J. Y. Johnson.—From C. F. Boehringer and Soehne. Preparation of alkylated uric acids. Nov. 17.

17,693. L. Lederer. Preparation of hexymethylentetramin and its derivatives.

XXI.—PHOTOGRAPHY.

APPLICATIONS.

23,917. R. W. Sharp. Appliance for photographing by acetylene light. Oct. 18.

24,021. A. G. C. Hunter. Improvements in and connected with photographic dry plates, films, and the like. Oct. 19.

24,763. W. H. Fellows. Improvements in or relating to photography. Oct. 26.

24,942. T. Raab. Method of, and means for obviating marginal cloudiness in photographic pictures on films. Oct. 27.

25,433. W. J. Holt. Improvements in the obtaining of coloured reproductions or prints from photographs. Nov. 2.

25,933. A. Schwarz. A new or improved process for the treatment of sensitised photographic paper. Nov. 8.

26,122. C. E. Benham. Benham's ink process of photography. Nov. 10.

XXII.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

24,136. A. Luck and C. L. Nichols. Improvements in the manufacture and production of explosives. Oct. 19.

24,195. I. Braly. Compositions suitable for the manufacture of matches. Complete Specification. Date applied for, March 30, 1897, being date of application in France. Oct. 20.

24,385. G. Bencké. Improvements in the waterproofing of blasting cartridges and new waterproofing compounds suitable therefor. Oct. 21.

25,204. J. C. Chapman.—From C. W. Volney, United States. An improved manufacture of gunpowder. Complete Specification. Oct. 30.

25,413. J. C. Chapman.—From C. W. Volney, United States. An improved gunpowder. Complete Specification. Nov. 2.

25,806. O. Hohnrodt. An improved fog-signal for railways. Nov. 6.

26,174. C. E. Bichel. An improved process for the preparation of nitro-glycerin explosives. Nov. 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1896.

25,704. A. E. Pike and W. H. Thew. Manufacture of explosives or explosive compounds. Nov. 17.

26,819. T. Jenkins. Charges of detonating railway fog-signals. Oct. 27.

XXIII.—ANALYTICAL CHEMISTRY.

COMPLETE SPECIFICATION ACCEPTED.

1897.

23,321. F. Hegershoff. Centrifugal machines for examining and testing milk, sediments of urine, and other fluid substances. Nov. 17.

PATENTS UNCLASSIFIABLE.

APPLICATION.

24,985. G. Barker.—From L. Rissmuller, Germany. Process of and apparatus for the treatment of waste matters. Complete Specification. Oct. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

1897.

8227. G. L. Schaefer. Improvements in chemical compounds. Nov. 17.

23,126. A. J. Boulton.—From A. O. Richter, Germany. Compound for use in extinguishing fires. Nov. 17.

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 12.—Vol. XVI.]

DECEMBER 31, 1897.

[Non-Members 30. per annum; Members 21. per Set of extra or back numbers; Single Copies (Members only) 2 6.]

## The Society of Chemical Industry.

### Past Presidents:

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dowar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
J. Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
T. E. Thorpe, LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Dr. Edward Schunck, F.R.S.	1896—1897.

## COUNCIL FOR YEAR ENDING JULY, 1898.

President: Prof. F. Clowes, D.Sc.

### Vice-Presidents:

David Howard.	Dr. W. Jay Schieffelin.
Prof. A. K. Huntington.	Dr. Edward Schunck, F.R.S.
Evan Levinstein.	G. N. Stoker.
Boverton Redwood.	Dr. T. E. Thorpe, F.R.S.
Sir H. E. Roscoe, F.R.S.	Wm. Thorp, B.Sc.
A. Gordon Salamon.	Thomas Tyrer.

### Ordinary Members of Council:

R. Forbes Carpenter.	C. C. Hutchinson.
R. Le Neve Foster.	J. S. McArthur.
Sir David Gamble, Bart., C.B.	B. E. R. Newlands.
Oscar Guttman.	John Pattinson.
Douglas Herman.	Sir Robert Pullar.
Prof. J. J. Hummel.	Walter F. Reid.

With the Chairmen and Secretaries of Sections.

### Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

### Honorary Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices: Palace Chambers, 9, Bridge Street, Westminster, S.W.

## THE JOURNAL.

### Publication Committee:

The President.

## NOTICES.

### COLLECTIVE INDEX.

In reply to numerous inquiries, the compilation of the Collective Index is in active progress, half of the work being already in the printers' hands. The labour of revision and correction must, however, of necessity, take time: and it is hoped that those members who have already subscribed will extend their indulgence to the Indexer, who is making every effort to complete this vast work.

The prices are as follows:—

To Members (see Rules 25 and 27) and Past Members (see Rule 30): Libraries, Corporations, and Exchanges on the Society's List

	Each copy 10s.
To Subscribers .....	12s. 6d.
To others.....	15s.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed. The circulation of the Journal is now more than 3,000 per month.

Members are reminded that the subscription of 25s. for 1898, payable on January 1st, 1898, should be sent in good time to the Treasurer, in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th next.

## TELEGRAMS.

The code address of Palace Chambers is "Palatable, London," and the Society's number is 59. Hence telegrams need only be addressed "59, Palatable, London," without words "Society of Chemical Industry."

## LIST OF MEMBERS ELECTED 23rd DECEMBER 1897.

- Barnett, Robt. C., Leeds Technical School, Cookridge Street, Leeds, Headmaster.
- Birchmore, Dr. Woodbridge H., Room 7, 117, Nassau Street, New York City, U.S.A., Gas Expert.
- Brakes, Jas., c/o Chateaugay Ore and Iron Co., Lyon Mountain, N.Y., U.S.A., Analytical Chemist.
- Bryson, Jas., Pumpherson Oil Works, Mideclder, N.B., Oil Works Manager.
- Bucknill, John A. S., 3, Crown Office Row, Temple, E.C., Barrister-at-Law.
- Batters, Chas., P.O. Box 1891, Johannesburg, S.A.R., Metallurgist.
- Calder, Wm. A. S., c/o Messrs. F. C. Hills and Co., Chemical Works, Deptford, S.E., Chemical Manufacturer.
- Cawley, T. A., c/o The Bristol Manufacturers, Ltd., Stillhouse Lane, Bedminster, Gloucester and Gelatin Manufacturer.
- Christie, Wm., 30, Addington Road, Bow, E., Chemical Works (Commercial Gas Co.) Manager.
- Dakin, H. D., Caledonian House, Caledonian Road, Leeds, Assistant Analyst.
- Dennis, Jno., Ellonville, Dalkeith, N.B., Contractor.
- Freestone, Jos. T., 1, Alexandra Terrace, Bedford Road, Roek Ferry, Cheshire, Manufacturing Chemist.
- Galletly, J. Clark, 101, Armadale Street, Dennistoun, Glasgow, Assistant to Professor of Metallurgy.
- Gent, Wm. T., Springfield, Misterton, near Gainsboro', Metallurgical Chemist.
- Gilligan, Jno. Vanner, Turret House, Reading, Taunton.
- Harger, Dr. Jno., M.Sc., The Nook, St. James' Mount, Liverpool, Chemical Student.
- Hibbard, Paul L., Nebraska City, Neb., U.S.A., Starch Chemist.
- H. H. Herbert M., University of Buffalo, N.Y., U.S.A., Professor of Chemistry and Toxicology.
- Johnson, Edw. H., Meyer and Charlton G. M. Co., Ltd., Box 27, Johannesburg, S.A.R., Cyanide Works Manager.
- Kipping, Prof. F. Stanley, University College, Nottingham, Professor of Chemistry.
- Kirkland, Robt., Viewfield, Newmain, N.B., Chemist.
- Laird, Robt. H., 652, Bowling Green Building, Broadway, New York, U.S.A., Metallurgist.
- Langmuir, A. C., c/o Ricketts and Banks, 104, John Street, New York, U.S.A., Analytical Chemist.
- Maephail, W. B., Hampson Mills, Bury, Lancashire, Soap-maker.
- Morris, Harry, Avenue House, Doncaster, Chemical Merchant.
- Oliver, Francis G., M.D., Trichinopoly, India, Consulting Physician (S. I. Ry.).
- Parker, Matthew A., 13, Hamilton Crescent, Partick, Glasgow, Assistant to Professor of Chemistry.
- Pidduck, E. V., 73, Lord Street, Southport, Lancashire, Works Chemist.
- Reid, Andrew, Pumpherson, Mideclder, N.B., Chemist.
- Robinson, Clarence J., 73, West 5th Street, Bayonne, N.J., U.S.A., Chemist.
- Shorey, Edmund C., D.Sc., Kohala, Hawaii, Hawaiian Islands, Chemist.
- Sjerry, Erwin S., 208, Colorado Avenue, Bridgeport, Conn., U.S.A., Metallurgist.
- Tetlow, Wm. E., Ash Cottage, Ashfield, Dunblane, N.B., Chemist.
- Towns, Jas., c/o Nobel's Explosive Co., Ltd., Perranporth, Cornwall, Chemical Works Foreman.
- Towse, Walter, Herold's Institute, Drummond's Road, Bermondsey, S.E., Technical Chemist.
- Trotman, Samuel R., University College, Nottingham, Public Analyst.
- Whitehead, Robt. J. G., 4, Lethington Avenue, Langside, Glasgow, Chemist.
- Wiborg, F. B., The Ault and Wiborg Co., Cincinnati, Ohio, U.S.A., Manufacturer.

## CHANGES OF ADDRESS.

- Baker, Theodore, 10 Belford; Box 281, Keyport, N.J., U.S.A.
- Buchanan, Joshua, 1/o Johannesburg; Marie Louise G. M. Co., Ltd., P.O. Box 84, Roodeport, S.A.R., Cyanide Manager.
- Burgess, G., 1/o Ditton; Hale Road, Halebank, Widnes.
- Bush, Baron W. de; Journals to c/o W. J. Bush and Co., Ltd., Ash Grove, Hackney, E.
- Chadwick, Walter N.; Journals to County Hotel, South Shields.
- Crowder, Wm.; Journals to Assay Office and Laboratory, 271, Evering Road, Clapton, N.E., Chemist and Assayer.
- Edwards, H. W., 1/o Santa Monica; 724, South Clarkson Street, Denver, Colo., U.S.A.
- Farmer, John E.; Journals to 25, Woodlands, Weaste Road, Weaste, Salford.
- Field, E. W.; Journals to Cloud House, Sandiacre, near Nottingham.
- Frankel, Dr. L. K., 1/o Marshall Street; 103, North Front Street, Philadelphia, Pa., U.S.A.
- Glaser, C., 1/o East Lombard Street; 21, South Gay Street, Baltimore, Md., U.S.A., Analytical and Consulting Chemist.
- Greiff, R. W., 1/o 3; 20, Eastcheap, London, E.C.
- Haga, T., 1/o Kantstrasse; Pestalozzistrasse 105, Charlottenburg, bei Berlin.
- Hills, Harold F., 1/o New Zealand; 147, Bow Road, London, E.

SESSION 1897-98.

Monday, Jan. 3rd, 1898:—

Prof. H. R. Procter and Dr. J. Gordon Parker. "Standard Methods for Analysis of Tanning Materials."

Dr. J. Gordon Parker. "The Effect of Different Temperatures on the Extraction of Tanning Materials."

Messrs. J. H. Coste and E. J. Parry. "Nestsfoot Oil."

Monday, Feb. 7th, 1898:—

Messrs. A. R. Ling and J. Baker. "Clegg's Method of Estimating Sugar, and a New Modification of it, specially applicable to After-Products and Molasses."

Mr. Thos. Fletcher. "Note on an Improved Drip-proof Bunsen."

Mr. Eug. Ackermann. "Notes on Cement."

Meeting held on Monday, December 6th, 1897.

DR. R. MESSEL IN THE CHAIR.

## THE SULMAN-TEED (BROMO-CYANIDE) PROCESS OF GOLD EXTRACTION.

BY H. LIVINGSTONE SULMAN AND FRANK L. TEED.

THE reaction upon which our gold extraction process is based was described in a paper read by one of us before the Institution of Mining and Metallurgy in 1895. At that time we were, however, unable to give any results beyond those obtainable in large laboratory practice, the largest ore extractions then available being from some 2 cwt. up to 1 ton.

Faraday and also Prince Pierre Bagration (Jour. prakt. Chem. **31**, 367) observed the solubility of metallic gold in potassium cyanide, and both noted that the solution was assisted by air. Dr. L. Elsner (Jour. prakt. Chem. **37**, 441) proved that the presence of oxygen was necessary. It may come as a surprise to some to learn that the oft quoted Elsner equation is not contained in this paper. But since it embodies Elsner's views it may still retain his name:  $4KCy + Au_2 + H_2O + O = 2KAu_2Cy_2 + 2KHO$ .

No mention of the necessity of the presence of oxygen is made in any one of the MacArthur-Forrest series of patents, and Mr. J. S. MacArthur denied this necessity as late as 1890 (this Journal, 1890, 270).

Elsner's original observations as to the necessity of the direct intervention of oxygen in the solution of gold by cyanide have since been confirmed by Skey in New Zealand, and more recently by J. S. MacLaurin (this Journal, 1893, 359), whose conclusions are:—1. That oxygen is necessary for the dissolution of gold in potassium cyanide, and that it combines with the potassium of the potassium cyanide in the proportion required by Elsner's equation. 2. That the rate of dissolution of gold in

potassium cyanide solutions passes through a maximum in passing from dilute to concentrated solutions, and that this remarkable variation is capable of explanation by the fact that the solubility of oxygen in cyanide solutions decreases with the concentration.

Prof. Christy confirms Elsner and MacLaurin.

MacLaurin's paper makes the vexed question of "selective action" perfectly clear, and it is now pretty obvious that a cyanide solution will dissolve base metal from an ore as a function of its strength, but will dissolve gold as a function of its strength and its oxygen contents. Since MacLaurin's proof that the oxygen dissolved is an inverse function of the cyanide strength, it became a pretty problem to determine the best practical strength, so as to give the maximum solution of gold with the minimum of base metal. The answer to this problem naturally varies with the ore and with the method of working, but we believe that the strongest liquors now employed seldom exceed 0.3 per cent of potassium cyanide, and may go down to a tenth of that strength.

The solvent power of a cyanide solution in practice depends on the oxygen supplied from air (1) previously dissolved in the liquors, (2) entangled between the grains of ore or tailings, and (3) dissolved by the surface layers of liquid and slowly diffused throughout the mass during leaching.

These supplies are sufficient to effect the fairly rapid solution of the finer particles of gold at the commencement of the leach, but the varied applications of strong and weak solutions, the necessity in many cases of alternate drainings of the partially extracted ores, and, in general, the effecting of as much aeration as possible, all point to the comparatively rapid exhaustion of the oxygen supply, and consequently to the intermittent nature of the solvent action occurring with simple cyanide liquors. The coarser the gold particles and the richer the ore, the more striking does the necessity of oxygenation become. The difficulty in extracting rich pyritic concentrates by the ordinary cyanide method, and the great length of time required, is partly due to this among other factors; and it is not all to be laid to the more or less complete overlaying of gold laminae by crystals of pyrites. Moreover, the large masses of pyrites and other oxidisable minerals immersed in alkaline solutions intercept the oxygen supply necessary for the dissolution of the gold, thus lengthening the latter process and enabling the cyanide to be destroyed partly by the oxidised products formed and partly by greatly prolonged contact of the cyanide with the naturally occurring compounds of the base metals.

Many attempts, embodied in numerous patents, have been made to improve the cyanide process by the employment of oxidising agents as a substitute for, or adjunct to, aerial oxygenation, but these "oxidation" improvements are already practically obsolete.

Any cyanide oxidised to cyanate is so much loss, MacLaurin having proved that cyanate has no influence on the extraction of gold.

If oxygen *must* be used, air is the safest and cheapest source. The inevitable defects, however, in all air-oxygenation—or chemical oxidation—cyanide processes are:—

(1) The slow oxidation of pyrites and other base sulphides, with consequent destruction of cyanide and loss of oxygen.

(2) The production of caustic potash as a necessary reaction product of the solution of the gold.

With free-milling or well-oxidised ores, containing none of the worse "cyanicides," the production of caustic alkali is not harmful, and may even be useful; but directly sulphides of iron, copper, arsenic, lead, zinc, antimony, &c., make their appearance in an ore, soluble metallic and sulphide compounds are produced from them (mainly by reason of the caustic alkali formed), which react directly on the cyanide and destroy it.

The oxygenation-cyanide process is, as a rule, inapplicable in the following cases:—(1) To ores containing coarse gold *only*. These may at once be dismissed as being fit subjects for the cheapest method of gold extraction, *viz.*, amalgamation. (2) Rich pyritic ores and concentrates. These, where not too heavy in gold contents and under specially

favourable conditions, may be occasionally treated by cyanide; but general Transvaal practice, even when the cyaniding can be done—as, for instance, with the Robinson concentrates—is to fall back on roasting and chlorination.

(3) Ores containing arsenical or copper pyrites, even in moderate quantities.

After a long search for an accelerator which shall not be an oxidising agent, we find that when a haloid compound of cyanogen—in practice, bromide of cyanogen is found to work best—is present with cyanide of potassium, the rapidity of the solution of the gold is greatly increased. Bromide of cyanogen *per se* is no more a solvent of gold than potassium cyanide *per se*.

The following equation represents the main chemical reaction that takes place, although there may be, and in fact are, other minor changes taking place at the same time:—

This is a pure cyanidation reaction, quite distinct from an oxidation one. No air is necessary, since oxygen takes no part in the reaction. No caustic potash results from the reaction, so that the evil results which it causes with certain ores are avoided.

Many attempts have been made to prove this reaction to be only another form of oxidation. All such theories, however, require the intervention of *hydrolysis*. That hydrolysis is extremely improbable, is evidenced by the stability of the simple aqueous solutions of these haloid compounds, especially when below 1 per cent. in strength.

It has been suggested that thermo-chemistry might explain the greater rapidity of our solvent. It, however, points the other way, more heat being produced by Elsner's equation than by ours.

Comparing the thermal equations of the two types of solvent, and eliminating from each the heat of formation of potassium aurocyanide, as common to both, we have:—

(1) Aero-cyanide type—

Heat liberated by oxidation of 2K to 2KHO.....	Calories.
Heat absorbed by dissociation of 2 KCy ....	= 164.6
Balance .....	= - 120.4
Balance .....	+ 35.2

(2) Halo-cyanide type—

Chlorine is here taken for the comparison, no data as to the heat of formation of bromide of cyanogen being available:—

Heat liberated by formation of KCl.....	Calories.
Heat absorbed by dissociation of KCy.....	= 109.8
Heat absorbed by dissociation of ClCy .....	= - 61.7
Heat absorbed by dissociation of ClCy .....	= - 9.9
Balance.....	= + 26.2

Both reactions are therefore exothermic, but on paper the balance of advantage is certainly in favour of the oxygen combination. The explanation of the total reversal of thermo-chemical indications in practice is that, in the case of the aero-cyanide type of solvent, the thermo-chemical equation represents an ideal condition of affairs, which actual physical factors render impossible of realisation.

Assuming the solubility of oxygen in dilute potassium cyanide solution is the same as in water, and that oxygen constitutes one-fifth of the atmosphere, calculation (on the basis of Elsner's equation) shows that 18 cb. ins. of plain cyanide solvent would be required to dissolve one grain of gold. If every particle of solution were brought into contact with every particle of ore, applying a weight of solvent equal to one-third of the weight of the ore, the aërocyanide solvent could not possibly extract more than 2 oz. 2 dwt. 9 grs. of gold per ton of ore. In the above calculations it is assumed that no oxygen is wasted on oxidisable matter in the ore, but also that no atmospheric reoxygenation takes place during the progress of the extraction.

It would only require rather less than half a cb. in. of a solution of 0.1 per cent. of potassium cyanide and 0.025 per cent. of bromide of cyanogen to dissolve 1 grain of gold, or a solution weighing one-third the weight of the ore would extract as a maximum about 80 oz. of gold per ton of ore. The advantage of our solvent is its great superiority in "potential" cyanogen.

A gold extraction process by leaching methods is not confined to the application of a solvent, but may be divided into three parts: (1) The solution of the gold from the ore, (2) The precipitation of the gold from its solution, and (3) The gold clean-up, or separation of the gold from its accompanying precipitant.

Fig 1.

GENERAL DIAGRAM OF PLANT.

In our method of precipitation we employ the finely divided by-product known as "zinc fume." Great difficulty was experienced at first, in large scale operations, in inti-

mately mixing the small requisite quantity of zinc fume with a large mass of gold-bearing liquor. Ultimately, the simple form of apparatus now known as a "zinc cone"

was evolved. The diagram shows this to be a light metal cone standing on its apex; it is charged with a certain small amount of zinc fume in the state of an emulsion. The gold-bearing liquors rise through an opening at the apex, become thoroughly mixed with the cloud of zinc fume, and then, as the liquors rise further, their velocity becomes so small by reason of the increasing area, that the suspended zinc fume and gold-zinc is completely deposited before the precipitated liquors flow over the upper circular edge of the cone. The cone combines the following factors:—(1) Completeness of admixture; the extremely finely-divided zinc being presented continuously to every portion of the liquor in a great excess for a short time, whereby the liquid is brought into almost molecular contact with the precipitant. (2) The clarifying of the liquors by continuous deposition. (3) The production of rich gold-bearing zinc precipitate (which can be obtained containing as much as 30 per cent. of gold).

The enormous surface exposed by a given weight of zinc fume, when compared with that of zinc shavings, enables the former to precipitate the gold much more rapidly and, therefore, during given equal times, more completely than is possible by the application of zinc shavings in practicable systems of zinc boxes.

This method of treating solutions by zinc to recover their contents of other more electro-negative metals is naturally not confined to the treatment of the liquors obtained by our particular solvent; it is applicable to ordinary cyanide liquors, and in fact to any liquor, acid, alkaline, or neutral, containing dissolved metal precipitable by zinc.

The third operation is the gold clean-up. Whether from the MacArthur zinc boxes or from our zinc cones, the gold-bearing precipitate has to be freed from the accompanying zinc for conversion into bullion. The somewhat elaborate process adopted for the ordinary zinc-box "gold slimes" would be equally applicable to our product. We prefer, however, to distil the air-dried gold-bearing zinc from a retort, leaving the gold behind, and again recovering the zinc in the very form in which it is required—zinc fume.

Before entering on the description of practical working we may add a word as to the testing of liquors. Cyanide liquors are tested in the same manner as cyanide liquors from the MacArthur-Forrest process. When the amount of bromide of cyanogen has to be determined, however, recourse must be had to a reaction which we think has a certain amount of interest apart from its technical application. Bromide of cyanogen mixed with excess of potassium iodide and acidified with hydrochloric acid, liberates iodine in the ratio expressed in the equation—

The liberated iodine is determined in the ordinary manner by thiosulphate. Excess of cyanide does not interfere with the reaction, and consequently the text books that state that iodides cannot be detected in presence of cyanides by means of chlorine or bromine require amendment. Bromide of cyanogen is a most excellent reagent for detecting traces of iodides, as it has not the property, when used in excess, possessed by free chlorine and bromine, of converting the liberated iodine into colourless iodic acid. We have successfully detected iodine in sea-water, without previous concentration, by first shaking with zinc fume, and then, after filtration, adding bromide of cyanogen, hydrochloric acid, and starch water, viewing the water in a foot tube.

We have now to consider our process as applied in practice, and for this purpose we shall take two mines, as examples, where the ores are as dissimilar as possible:—

Day Dawn (West Australia), where the process is worked upon battery tailings from a free-milling ore; and Deloro (Canada), where we are extracting an ore *direct*, without any preliminary roasting or chemical treatment, consisting of massive arsenical pyrites often carrying over 40 per cent. of arsenic.

**Crushing.**—At Day Dawn the ore is battery-crushed from 25 to 30 mesh to the linear inch, and passed over plates, and the tailings only are treated. The gold is simply as it has escaped in the quartz sands from the battery plates, and is mostly fine and accessible. The tailings are taken straight

from the battery pits or from the tailings heap, and when from the latter contain about 15 per cent. of air-dried and agglomerated slimes.

Fig. 2.

GRUSON-KRUPP MILL.

At Deloro, the gold is in a laminar condition between crystals of arsenical pyrites. The ore is there crushed by a Krupp Grusonwerk ball mill to 30–40 mesh. A certain amount of fines is separated by an air grader. This part of the process is in course of modification, as it is found that, despite many applications of the principle of air separation, a large proportion of still leachable though fine material is carried off with the unleachable slimes by means of applied air currents. In several cases investigation showed that the air-separated product contained 40 to 60 per cent. of material, which, though very fine, was still granular enough to have been dealt with in the leaching tank. To retain this it has been found desirable to have recourse to wet separation, whereby not only is the mass of the fines greatly reduced, but the absolute slimes rejected by it are very much poorer than the average product separated by an air current. Slimes from Deloro ore by wet separation can be obtained as poor as 3 dwt. per ton, or even less, whereas the dry separated material often runs from 8 to 9 dwt.

At both mines the crushed ore or tailings is simply dumped direct into the leaching vat. Both plants are for working 50 tons a day.

**Extraction.**—No preliminary wash of acid, alkali, or water is used at either mine. At Deloro a preliminary alkali wash was found to considerably increase the cyanide consumption without any compensating advantage in the subsequent extraction. It was accordingly discarded. We have found this result constantly reproduced in treating heavily arsenical-pyritic ores.

In addition to the ordinary cyanide plant, a bromide or cyanogen solution tank is provided, which is shown on the elevation of the plant and in some of the photographs. It is made of wood throughout, provided with a gauge glass graduated in gallons, is fitted with an air-tight cover, a spigot cock outlet, and a vent orifice, to admit the necessary air in running off the liquor. No metal is used in its construction. There is also a perforated wooden box placed centrally over the extraction vat, into which the delivery pipe of the cyanide liquor is taken, and into which also the bromide of cyanogen solution is conducted by a small rubber hose-pipe from its dissolving tank. The mixed liquor is thus spread on the charge of ore through the box perforations. The bromide of cyanogen solution

s prepared in its tank by direct solution of the solid product in water; at ordinary temperatures a 7 to 8 per cent. solution can be obtained. The perforated distributing box enables a fairly uniform mixture of the two liquors to be obtained before they are run upon the ore, and breaks up the heavy inlet current, preventing, by means of its rose-like discharge, "burrowing" into the surface of the ore charge.

In addition to the bromide tank there is the usual strong cyanide or dissolving tank (250 galls.) placed over or near the sump tank, fitted with a sieve and counterbalance. The sieve is provided with a cane bottom, over which is placed twill or calico; upon this rest the lumps of cyanide of potassium required for making up the strong liquor. A small pump circulates the liquor round and round on to the sieve until the solution of the cyanide is completed. The amount of strong potassium cyanide required to be added from time to time to the leaching liquors is calculated from the analysis of the sump liquor, and the necessary addition of strong liquor is run into the sump store. It is important to note that the cyanide and bromo-cyanide solutions are kept separate and are only mixed immediately before use.

The addition of bromide of cyanogen is proportioned to the work to be done, calculated from a previous trial. Any unnecessary excess should be avoided, as it does not survive (as bromide of cyanogen) its passage through the zinc cone. Speaking generally, it should not exceed, as a maximum, one quarter of the weight of the cyanide of potassium present, though in most cases a less proportion of bromide of cyanogen than the above is found to suffice.

In charging the ore with the mixed solutions, the vent peg of the bromide tank is loosened, and the spigot tap turned partially on, so that the calculated quantity of strong bromide of cyanogen liquor shall be roughly apportioned in its rate of flow to the time occupied running on the main charge of cyanide liquor.

A circulating pump is attached to the leaching tank having its inlet below the filter bottom, and its outlet, returning over the top of the tank. When the addition of the mixed bromo-cyanide leaching charge to the ore is completed (about one-third of the weight of the ore), the liquors may be circulated for two or three hours, until fairly uniform in composition. The circulation may be repeated at intervals if desired.

The time of extraction is 14 to 15 hours at Day Dawn and 30 to 40 hours at Deloro, the difference being entirely due to the very different distribution and occurrence of the gold particles in the two ores. At Day Dawn only one set of liquors is used, averaging 0.1 per cent. or less of potassium cyanide, with a proportionate amount of bromide of cyanogen. At Deloro, two sets are employed: the strong, 0.2 to 0.25 per cent., and the weak, 0.1 per cent., of potassium cyanide, each with its small requisite addition of bromide of cyanogen. The consumption of chemicals is at Day Dawn rather less than 1 oz. of potassium cyanide and 1½ oz. of bromide of cyanogen per ton of ore. At Deloro it is 1 lb. of potassium cyanide and ½ lb. of bromide of cyanogen per ton of ore. The percentage of extraction averages about 90 per cent. at both mines. At Day Dawn the tailings average 3 to 4 dwt., and the residue, after extraction, 8 to 10 grains.

On more than one occasion these 14 hours extracted tailings were boiled with aqua regia, when no further diminution of the residual gold contents was effected, thus proving a complete extraction of all exposed gold by the short bromo-cyanide leach. It is of course obvious that no process that does not dissolve quartz can attack a particle of gold completely surrounded by quartz.

In endeavouring to ascertain the minimum amount of cyanogen bromide necessary, it was once reduced to ¼ oz. to the ton of ore; here the solution began to approximate more nearly to one of plain cyanide. After two days the extraction was still imperfect, but on the addition of the balance of bromide of cyanogen, it was completed in a few hours. This experiment very clearly demonstrates on a practical scale the immense advantages of bromide of

cyanogen as an accelerator even in the case of tailings from a clean quartz ore.

We would here remark that it was the work done at Day Dawn by one of the authors and Mr. Hans Knutsen which primarily established the great superiority of bromo-cyanide over plain cyanide in dealing even with free milling tailings. The details of precipitation and the overcoming of some difficulties, both in this and the clean-up, not at first experienced there, were worked out by Mr. Hugh K. Picard at Deloro, in treating this highly refractory ore.

The Deloro ore averages about 17½ dwt. of gold to the ton, and "is an arsenical sulphuret of iron, in a gangue of quartz and calc spar, an analysis of which gives about 42 per cent. of arsenic, 20 of sulphur, and 38 of iron" (Lock, "Practical Gold Mining," p. 667). Mr. Picard's experience is that it always contains small though variable quantities of copper pyrites, also slate and mica. The crushed material treated, varies from 25 per cent. of mispickles up to a mass containing sometimes as much as 40 per cent. of arsenic. It is roughly hand-concentrated, as the mispickles carries practically all the gold. It was formerly treated by the Mears process of chlorination, after hand-picking, concentration by jigs, and roasting (*ibid.* p. 665). But this process proved a complete economic failure. Experiments were conducted to see whether plain cyanide treatment would not suffice for the ore, but they were quite unsuccessful. It may be taken as a generally granted fact, that ores containing a notable proportion of arsenical pyrites are debarred from the ordinary cyanide treatment. In this particular case we have therefore supplanted both chlorination and plain cyanide treatment.

In Deloro ore 50 per cent. of the gold can occasionally be extracted by bromo-cyanide in six hours. Such amount may be regarded as the immediately available or freely accessible gold, *i.e.*, where the gold film lying between the crystals of pyrites has been thoroughly exposed by the removal of one of the overlying surfaces. After these free films have been dissolved, those imprisoned between the pyritic surfaces have to be attacked edgewise—a much longer operation—so that the total time amounts to from 30 to 40 hours.

It was found here that, with the ore only crushed to from 20 to 25 mesh, extraction ruled low—often only 65 per cent.—whereas, upon crushings carried to from 35 to 40 mesh, the 90 per cent. removal was again obtained. These experiences indicate that it is not the presence of the arsenical pyrites from a chemical point of view that prevents the total extraction of the gold, but the fact that it actually mechanically encloses the gold. As is generally the case, finer crushing exposes more gold, and permits of a higher extraction.

Bromide of cyanogen being a solid is more readily taken by shippers than bromine. It is exported in hundred-weight and half-hundredweight cases, lined with 5 lb. lead, previously tested by hydraulic pressure to 30 lb. to the square inch. The case is not opened until required, and then the whole of the contents is emptied into the bromide of cyanogen tank.

The total bromide of cyanogen admixture requisite to an ore charge is not necessarily made all at once, but may be in two or more additions, during circulation, from time to time. This is found advisable when, from the laminated and partially enclosed nature of gold films held between crystals of pyritous or similar minerals, the extraction is necessarily somewhat prolonged.

A point of much importance, from its being a divergence from ordinary cyanide practice, requires mention. The dissolved gold salt in even dilute bromo-cyanide liquors is so very stable that, in spite of all cyanide experience to the contrary, it is found not only convenient, but desirable, to make one charge of liquor extract several vats of ore in succession, without intermediate precipitation. Even with the extremely refractory Deloro ore, no tendency whatever to reprecipitation of the gold in the fresh ore charge is noticeable. One batch of liquor is usually made to extract four vat charges of ore, and even five vats have been successfully extracted, before passing the liquor through the zinc cone. The bearing of this method on economy in precipitation is evident.

**Precipitation.**—We prefer to at once discharge the whole of the gold-bearing liquor derivable from the extraction vat into an intermediate drainage sump; by so doing, two advantages accrue: (1) It enables the gold-bearing liquors to be run off from the exhausted charge much more rapidly than would be the case if the rate of withdrawal were made dependent upon the comparatively slower rate of flow necessitated through a precipitation plant; the leaching

tanks are thus freed more quickly for the reception of a fresh charge of ore. (2) We also secure that uniform quality and strength of liquor and rate of flow through the plant which is so essential to the best results in any precipitation method.

We prefer to use two zinc cones in series, placing the one 2 or 3 feet above the other. They are constructed of light sheet iron, painted with zinc fume in linseed oil, or

Fig. 3.

may be made direct from galvanised sheet iron. They are about 5 ft. to 5 ft. 6 ins. top diameter, and of similar depth. Round the top of each is fixed a circular gutter for collecting the uniform overflow of clear liquor, which is conducted thence, as the case may be, either from the first cone to the second, or from the second cone to the storage sump for precipitated or gold-free liquor.

The unprecipitated liquor enters through the bottom of the first cone from a small tank, placed to give some 2 or 3 feet of head above the top level of the cone. This tank is fed directly from the intermediate sump by a small plunger pump. The stream, on entering the bottom of the cone, is distributed by means of a small perforated inverted cone-nozzle, inside which is fitted a valve arrangement to prevent any backward flow of zinc emulsion from taking place when the cones are stopped. The bottom is also provided with a three-way cock, which either permits the inflow of liquor for precipitation, or shuts this off to permit the discharge of the gold-impregnated zinc fume as desired.

Occasionally a small "flock" of material, consisting of a few zinc-gold complexes, buoyed up with a bubble of

hydrogen gas, may rise through the deposition zone to the surface of the liquor in the cone. To prevent such coarse flocks being carried into the overflow, a screen, 3 ins. deep, of coarse calico, is placed around the overflow rim, and is carried by a circular rod supported on small standards. In the photograph, the calico screen itself has been removed to show these. The addition of fresh zinc fume is made in the form of thick emulsion in water, by means of the central small funnel shown. It has been found advisable in practice to again expand the bottom of this funnel for the purpose of producing a sort of vortex chamber at the bottom of the zinc cone, which ensures a more thorough admixture of the zinc fume emulsion with the inlet liquors.

Assuming the zinc cones to be full of old precipitated liquor, and the gold-bearing liquor from 100 tons of exhausted tailings to require precipitation (this gold-bearing liquor being of course in the intermediate sump), the following is the routine:—

The gold-zinc fume from cone No. 1 is removed for clean-up; the partly used gold-bearing fume from cone No. 2 is transferred to cone No. 1, and a charge of about

2 lb. of fresh zinc fume in an emulsion with water is run to cone No. 2. The gold-bearing liquor is now run through the series at the rate of 400 to 600 galls. per hour, and occasionally even at a greater rate.

Fig. 4.

CONE AND CIRCULATING PUMP—DELORO.

The zinc cone automatically grades the zinc particles, if of varying degrees of fineness, so that the heavier, coarser particles are in the richest gold-bearing stratum, and the liquor, in rising through the cone as it becomes poorer in gold contents, constantly meets finer and finer suspended particles of zinc. But inasmuch as these latter become weighed after a time with gold, there is a tendency for them to be withdrawn from the top zone of slow upward travel. For this reason it is found advisable to add about every one or two hours or so, some fresh zinc fume emulsion, containing about 1 lb. of dry material, through the central funnel.

The zinc consumption at Deloro over a period of four weeks (Oct. 1st to 28th) amounted to 0.54 lb. of fume per oz. of fine gold recovered.

Very little difficulty has been experienced from the overflow of even the most finely divided particles of zinc, but as a precautionary measure a small settling tank (containing slats, placed at an angle to the vertical, about half an inch apart, and extending across its whole width) is introduced between the second cone and the sump. This tank (omitted in the diagram) is interposed in case of a slight overflow of fine zinc fume on starting the precipitation, and effectually stops the passage to the sump of even the finest zinc particles; this small catchment tank only requires a very occasional clean-up. The consumption of zinc is very small, and the gold-bearing fume generally weighs only a pound or two less than the charge originally introduced. The precipitated liquor, as in the plain cyanide process, is used over again after being made up by an addition of strong cyanide liquor to its normal strength.

It has been found possible to reduce 1 oz. gold liquor (per ton) to 3 grains when passing through a single cone at the rate of 400 gallons per hour, and frequently the outlet liquors do not exceed 10 grains per ton. Such great closeness of precipitation is, however, in general, unnecessary, as the unextracted gold is not lost, but only represents a very small portion of locked-up capital. It never increases, as the liquors are used over and over again, and precipitated to this standard. In Canada it has not been found necessary to precipitate closer than 1 dwt. per ton, which is, however, a figure that is never exceeded.

After the passage of the whole liquor charge, the gold-zinc fume is removed, after a short settlement period, from the first cone by means of the three-way cock, in the course of a few minutes. It is then drained on a calico filter

preparatory for the final distillation (clean-up). As mentioned above, the fume from the second cone is transferred to the first.

We have not had occasion to treat very rich liquors as yet. The Deloro liquors run between 2 and 3 oz. to the ton, while those at Day Dawn are very much poorer. At the Hannans Brownhill mine, where a very large installation of the bromo-cyanide process is now in course of erection, much richer liquors will be obtained, as the ore will probably average from 3 to 4 oz. per ton. Here three cones will be used in series, and from preliminary trials it is anticipated that the zinc-gold fume removed from No. 1 cone will uniformly exceed 30 per cent. in gold contents. It is proposed to add an automatic zinc-fume feed to the cone series in this case, in order to make the necessary small additions of zinc fume uniformly and continuously.

**Clean-up.**—The clean-up by the zinc-box method consists in sifting the zinc shaving fragments, covered by the light purplish-brown deposit of powdery gold, upon sieves submerged under water. The larger fragments of zinc, retained upon the sieve, are returned to the richer zinc-box compartments, whilst the very fine and valuable deposit which passes through, much of it in a state of extremely fine suspension, is, after settling, washed with care by decantation (or in a filter press) and finally dried.

The first step in the removal of the zinc is careful roasting upon a suitable iron plate or hearth freely exposed to the air; but as a large proportion of the zinc *débris* is in fragments of sensible size, a complete oxidation by mere atmospheric means entails much time and trouble. Nitre is therefore frequently added to complete the oxidation. This addition may vary from a few per cent. upon the dry "gold-slims," as they are termed, to, in extreme cases, their own weight in nitre. The fully roasted charge is treated with a sufficiency of dilute hot sulphuric acid to dissolve the great bulk of the oxide of zinc as sulphate. The residue is now naturally very rich in gold contents, and is still highly divided; it is washed free from soluble zinc salts, collected, dried, and smelted with varying additions of borax, sodic carbonate, silica, &c., to obtain the bullion in ingots.

Mr. James has recently collated the sources of loss which arise from zinc clean-up, in a paper before the Institution of Mining and Metallurgy; and Mr. T. H. Leggett, in another paper before the same body, states: "In the roasting with nitre method in vogue on the Rand, the loss due to stirring and the escaping fumes is something the Rand metallurgists do not like to talk about." It is very difficult to form a just estimate of these losses, but we do not think they would be over-estimated if put at an average of 2 per cent. of the gold contained in the original gold-slims. Moreover, the process is a lengthy one, entailing several days' work, and necessarily implying the stoppage of the zinc boxes for a while. The clean-up under the zinc-box system naturally, therefore, only takes place monthly or bi-monthly, when the zinc shavings have become sufficiently rich to warrant it.

The Siemens-Halske electro-deposition process also consumes a very considerable time in the removal of the old gold-lead cathodes and their replacement in the frames by fresh lead sheets, &c. Moreover, the Siemens-Halske clean-up necessitates the expulsion off of an excess of lead, which, roughly speaking, constitutes about 90 per cent. of the weight removed from the precipitation apparatus.

In our process, the removal of the zinc-gold fume from the precipitation apparatus is effected daily, or after the passage of one or more charges of gold liquor through our plant, by the mere process of turning a three-way cock; and occupies, with the substitution of fresh quantity of zinc fume, only a few minutes; and the precipitation plant being dissociated from the leaching plant, no hindrance is offered to the general work of extraction. The removed zinc-gold fume is drained upon an ordinary calico filter.

The general impression among metallurgists is that zinc and gold cannot be heated together to the temperature of volatilisation of the former without serious loss of the latter. It is true that if gold and zinc be melted together in a muffle furnace through which a current of air is passing, the loss of gold is serious. We contend that the losses there experienced are caused through the oxidation of the

zinc, the gold being carried off mechanically entangled with the minute solid particles of zinc oxide. In the distillation of zinc-gold fume at Day Dawn, it was noticed that whenever oxide of zinc was allowed to issue from the mouth of the retort freely—that is, to be formed in the retort itself by a back-flow of air—the loss of gold during distillation of considerable charges became serious; and the interior of the flues which conducted away the fumes of oxide of zinc was soon found to be studded with minute beads of gold. Whereas in experiments in well-luted crucibles, when the zinc-gold charge contained a small proportion of carbon, and the temperature was sufficiently maintained to ensure a continuous current of metallic zinc vapour through a central escape orifice, so that air could not enter, the distillation of zinc from gold took place with almost complete absence of gold loss, the resulting bullion being found melted at the bottom of the crucible after completion of the operation over 800 in fineness. This led us to make a series of experiments as to the best means of employing the convenient form of zinc distillation plant known as the Balbach retort and furnace for our purposes. The difficulties attending the mechanical loss of gold did not cease entirely with the mere exclusion of oxygen, a further deficit being caused through the escape of permanent gases, and zinc vapour itself, in the form of small fountains or "geysers," through the hot, fine powdery retort charge. This difficulty has been brilliantly overcome by Mr. H. K. Picard, A.R.S.M. To the zinc gold fume, on removal from the final cone, he adds some soluble carbonaceous substance, such as gum, flour, flour-paste, starch, sugar, or molasses, together with a little borax. The resulting mass is dried down by any available gentle waste heat; the honey-dry cake is broken into lumps about the size of walnuts and charged into a capacious plumbago retort. A sheet-iron condenser is luted to the mouth of the retort and the furnace fired up. The organic admixture becomes carbonised and the zinc-gold contents are held bound together, though in an open spongy condition, by a fine carbonaceous skeleton. This serves to fix the finely divided contents temporarily while affording free passage to the escaping zinc vapours during distillation, and provides an excess of carbon to combine with any atmospheric oxygen that may enter. The loss of gold is thus reduced to a minimum. In the distillation of  $\frac{3}{4}$ -cwt. charges of zinc-gold fume, the condensed zinc and zinc oxide vapours, deposited in the sheet-iron condenser, show constantly upon assaying only slightly over 1 oz. of gold to the ton, or a total loss of less than 1 dwt. of gold on a charge of  $\frac{3}{4}$  cwt. of zinc-gold precipitate carrying 20 per cent. of metallic gold. This is a loss in gold clean-up of considerably less than 0.1 per cent. of the gold present in the precipitate. The metallic and oxidised zinc products deposited in the condenser run curiously constant in gold contents whatever be the richness of the zinc-gold fume distilled, namely, about 1 oz. to the ton. But the relative loss is so small that hardly any appreciable difference is made whether the gold-zinc from rich or poor liquor precipitation be distilled.

In the diagram given of the Balbach design of plant it will be seen that the condenser can be removed from the mouth of the retort when the distillation of the zinc is sufficiently perfect, and that thereupon the whole furnace can be tilted by means of the cog and worm wheel adjustment fitted to it.

As an example of zinc fume distillation, conducted at at Deloro, we may instance the following:—A 55-lb. charge of zinc-gold fume containing 70 oz. of gold was balled with 12½ lb. of sugar and 1 lb. of borax, the proportions adopted being roughly the use of 5 lb. of sugar and  $\frac{1}{2}$  lb. of borax to each 20 lb. of precipitate. It will be noticed in the photo of the distillation plant that a small tale door is provided at the back of the condenser, through which the progress of the distillation can be watched, and any accumulation of zinc oxide round the mouth of the retort may be removed, if necessary, once or twice during distillation, by means of a small rake or slice. The coal required for complete distillation is about 3 cwt. and the time 10 hours.

The ingot, cast direct from the retort, contained 64 oz. of gold out of 70 oz. possible, the remainder being in the few pounds of slag left, which one smelt in a No. 35 crucible

dealt with directly and recovered. Coal for remaining smelt, say 1 cwt.; so that the total coal used throughout is 4 cwt., = 1 dollar at Deloro. Add to this, share of a 7-dollar Dixon fireclay plumbago retort (assuming a retort to last four times only), say 2 dols., fluxes and crucible for subsequent smelt, say 1 dol. Total clean-up cost 4 dols., which Mr. Picard considers an outside figure.

Fig. 5.

ZINC RETORT AND FURNACE.

In Mr. Picard's latest reports, slightly less proportion of flux and molasses have been used, with the result that only 3 lb. of residual slag remained in the retort to be smelted after the gold ingot was tipped. The clean-up of 70 oz. of gold, say of value of 280l. sterling, thus consumed only 16s. worth of fuel, chemicals, &c., being under 0.3 per cent. We would also point out that this operation of clean-up takes place twice a week, or more often as required, as one of the ordinary operations of the assay house. No hindrance or dislocation of general work is caused by such a clean-up. The operations are kept in constant touch with the process, and the capital is recovered practically contemporaneously with the extraction of the ore.

On the scale of work at present proceeding, Mr. Picard estimates the cost of clean-up at rather less than 6 cents for every ounce of fine gold recovered. Were this scale increased to that of a Transvaal clean-up, this small cost would undoubtedly be further and considerably reduced.

We may summarise the results achieved:—

(1) The bromo-cyanide process exceeds the older cyanide process on its own ground, i.e. on free-milling battery tailings, both in rapidity and economy of extraction.

(2) The use of cyanogen in gold extraction has been extended to a province of refractory ores hitherto entirely beyond the reach of any process.

(3) The introduction of a new improved process for precipitating gold from cyanide and other liquors.

And finally (4) The clean-up of zinc-gold fume with an efficiency and simplicity not yet approached by other means.

In the working out of this chain of processes we have been greatly helped by the efforts of many able chemists. We gratefully acknowledge the highly important work accomplished by Mr. Hugh K. Picard, A.R.S.M., at Deloro. It is in a very great degree to Mr. Picard's efforts—ably aided by Mr. R. H. Harland, F.I.C.—that we are indebted for such a satisfactory demonstration of the capability of the bromo-cyanide process. To many other gentlemen we are indebted for practical help: to Messrs. L. G. Attenborough, A.R.S.M., F. B. Dick, and A. Carr, B.Sc. In Western Australia we received great assistance from Mr. Hans Kuntze—who first suggested the use of the Balbach form of furnace for distilling the zinc-gold charge—from Mr. Edwin Bull, and others.

With the advent of a direct leaching or percolation method, as typified by the older cyanide process, a fundamental reconsideration of the bases of gold extraction, and the dethronement of the battery as the universal gold-winning process, became only a question of time. The revolution has been slow in taking place, but it has been none the less sure. In perhaps the great majority of cases this will be to submit the whole of the suitably crushed ore to direct chemical extraction—thus removing fine and medium gold—and leaving the coarse gold particles in a cleaned condition far more amenable to amalgamation, which at this stage may suitably step in. The perfecting of the cyanide process, or, more widely, of leaching processes in general, must therefore have a far-reaching influence in the modern developments of gold extraction.

Whilst the old battery process, which, with the weapons at its command, was a perfectly rational one, took for its axiom, "Get the bulk of your gold as soon as you can"; the newer system, with the newer weapons at its disposal, rather takes as its motto, "Take care of the fine gold, and the coarse will take care of itself."

#### DISCUSSION.

Mr. W. CROWDER had followed the development of the process with great interest since its announcement at the Institute of Mining and Metallurgy two years ago. He was surprised, however, that no reference had been made to any possible application of the process to Transvaal gold ores, seeing that the Transvaal mines were now the source of the largest production. He regarded the use of zinc fume as a most important advance on the original process, since it effected its purpose admirably, without interfering with any other portions of the operations.

Mr. A. C. CLAUDET could not discover that the paper contained much more information than was given by the authors two years ago. It was not at work then on a large scale, but had been worked since in Canada and in Western Australia. No mention was made of the results of trials the speaker believed had been made in the Transvaal. It appeared to him that the portion of the paper relating to zinc precipitation had been elaborated to the loss of the paper as a whole. He would leave its discussion in the theoretical aspect to gentlemen more qualified in this respect than himself, but there were one or two practical points with which he would like to deal. In one experiment the authors stated they lowered the amount of bromo-cyanogen to 1 oz., and the extraction was immediately reduced, but they did not state the original strength of the solution. If thus lowered, in order to fairly show the result, the authors should have added its equivalent in cyanide. He did not understand that the application of the process was limited to refractory ores, as suggested by the Chairman, but that it was in all respects, and claimed to be, a competitor of the old MacArthur-Forrest process. It was noticeable, however, that no records of comparative experiments with the two processes were given, and therefore they had simply to accept the authors' statements. That

being the case, until such comparative results were forthcoming, he must reserve his judgment on the matter. He had himself made experiments with the Deloro ore, and he found that a very weak solution of ordinary cyanide would extract as much gold as the authors had claimed. The authors' retort to that would probably be that there was an economy in cyanide. On the other hand, it must be remembered that the whole of the bromo-cyanogen was absolutely lost; and in his opinion a true comparison of the two processes could only be got at after an extended series of trials side by side. From the precautions which the authors took to keep the air from the solution he concluded that the bromo-cyanogen was quickly decomposed, and he thought would probably disappear altogether in the course of three or four hours, after which time they would be working with ordinary cyanide only. If that were so, where was the gain? Neither was it stated that the process had paid anywhere. Much was said, however, of the advantages it would offer to the Brownhill Company; but they were not told whether the process was to be as described in the paper. As a matter of fact, this process, like all percolation methods, depended entirely on the nature of the ore dealt with. The ore there was a peculiar one, and he understood that the process used would be to treat the slimes or fine ore obtained by dry separation, equivalent to about 30 or 40 per cent. of the total ore crushed. He was, however, pleased to hear that the authors had experimented on the distillation of the zinc precipitate. He regarded that as an important advance. He had suggested that two years ago, because in the ordinary process the presence of zinc in the final bullion influenced very considerably the value obtained when sold. As the authors claimed that they refined their bullion, he would like to know what its fineness was at Day Dawn and at Deloro. He would also like to know whether the zinc contained lead, and if they preferred to use a zinc containing lead; in the latter case distillation would not remove the lead. He could not agree with the summary of the results claimed, because sufficient time had not yet elapsed to enable them rightly to estimate the value of the process.

Mr. R. H. HARLAND had some practical experience of the process, having made tests, in conjunction with Mr. Claudet, on a large scale in London, which led to its adoption at Deloro. Difficulties were encountered in the early stages, more especially with regard to the clean-up of the zinc dust, losses of gold taking place during distillation from a Balbach furnace. This had now been entirely overcome by the ingenious method, devised by Mr. Picard, of balling the zinc dust with sugar before charging into the retort. As to the purity of the zinc fume employed, one parcel used at Deloro contained—

	Per Cent.
Lead.....	1.74
Cadmium.....	0.69
Iron.....	0.11
Arsenic.....	Faint trace
Copper.....	Nil
Sulphur.....	"
Siliceous matter.....	0.19
Carbon.....	0.52

with a varying proportion of zinc oxide, 3 to 5 per cent. The same impurities in about similar quantity were found in all samples of commercial spelter, and no doubt their presence materially assisted in the rapid precipitation of the gold from the cyanide liquors. After precipitation through two cones the liquor contained from 1 to 3 dwts. per ton, and in some cases less than this. With properly regulated rate of flow and charge of zinc, the liquor from each cone was absolutely free from suspended particles of zinc dust.

At the mine mentioned about 1,300 tons of arsenical pyrites had been treated. The bullion produced without treatment by sulphuric acid was about 690 fine, and contained 25 to 28 per cent. of zinc; it was therefore not so pure as that obtained by the Siemens-Halske process, but the conditions of precipitation and clean-up were simple and entailed little trouble.

Mr. A. C. CLAUDET said it was quite true that he had watched the process, and the results obtained were favourable; but his remarks now were meant simply to indicate that

there was no apparent advantage after all in using the Sulman-Teel process instead of the old cyanide process.

Mr. D. A. LOUIS agreed with Mr. Crowder and Mr. Claudet that, with the exception of the new cone and the results of practical working which were now published, the authors had added very little to the information given in their former paper. On the new points not nearly enough had been said to enable one who, like himself, had no practical experience of the process, to form a judgment on their value. Mr. Claudet's statement that with a sufficiently dilute cyanide solution he could get as good an extraction as was claimed for this process, was very important, but he had omitted to say what time would be occupied, and how much cyanide would be used. These were essential points; and one would like to know also what else, if anything, was extracted with the gold. He had himself treated many ores—some very foul ores, and he ultimately got out the gold, but with it other metals of little value, and at an expense for cyanide greater than the value of the gold recovered. Under such circumstances, if no information were demanded as to the time occupied and cost of the cyanide used, one could correctly state that the gold was extracted by cyanide, but not that the extraction was economical or efficient; hence the value of supplying the missing information in such cases. He would like to hear more as to the equation  $\text{CyBr} + 3\text{KCy} + \text{Au}_2 = 2\text{KAu}^{1/2}\text{Cy}_2 + \text{KBr}$ , which suggested that the whole of the cyanogen was utilised solely in dissolving the gold; also as to the words "we get the same thing, but there is no hydrolysis"; and again as to the presumed cause of the great increase in the rapidity of the extraction. It was well known that in many cases weak cyanide solution would do all that was claimed by the authors; but the special advantages claimed for the present process were a decrease in the cyanogen used, and, what was very often still more important, a considerable saving in time under adverse circumstances.

Mr. H. DE MOSETHAL thought that the best assurance that the authors could give of the success of their process was that some among the large number of mines at present using the cyanide process had consented to adopt the addition of bromide of cyanogen to their liquors, and had found their results so improved as to warrant them in continuing to do so. Even if the improvement effected were only that of saving time, it would be sufficiently important, provided that saving was not effected at too great a cost in additional chemicals and royalty.

Mr. A. JAMES had hoped, with other speakers, to find some information about the bromo-cyanide process proper, and was disappointed to find that the authors had confined themselves so much to the zinc fume process, which was after all a secondary matter. With regard to the acceleration of the rate of solution, that was a point which could not be dismissed in a few words. There were times when the rate of speed of the solution was all important, and at such times the solution proposed by the authors would be of great efficiency, for it would undoubtedly, under certain conditions, dissolve the gold much more rapidly than would the ordinary cyanide solution. He found it difficult to agree with the authors when they said that the auro-cyanide solvent could not possibly dissolve more than 2 oz. 12 dwt. of gold per ton, as with exceedingly rich ores it was occasionally found that with a  $\frac{1}{2}$  per cent. solution nearly the full theoretical proportion of gold was extracted, or considerably over 100 oz. per ton. One point upon which the authors had given no information was the effect of the decomposition products. He assumed that they had overcome the difficulty which used to arise by the continued formation and accumulation of those products, which occurred to such an extent, even with a weak solution, as to make it impossible to attempt to re-use the solution. One point had a special interest for him. On page 951 the authors referred to the aurocyanide process as being inapplicable to certain ores, particularly mentioning Transvaal concentrates. Mr. Butters, the great authority on chlorination, had, however, himself stated that cyanide was slowly but surely displacing chlorination for all purposes on the Rand, even for the treatment of concentrates. He himself felt convinced that bromo-cyanide had its special function, but he thought the authors were mistaken in

claiming for it any superiority for the treatment of simple ores. Had they restricted their claims to special classes one might have agreed with them, but for simple ores general experience was against them. If one took two ordinary ores and ran them side by side, one with bromo-cyanide and cyanogen, and the other with plain cyanide, the result would be a greater decomposition of cyanide where the bromo-cyanide was present. On the other hand, if one took a special ore—one that contained marcasite, for example—then the decomposition might be greater with the plain cyanide, owing to the longer time required for treatment by the latter method. The reason for this was that the addition of bromo-cyanide had the effect of increasing the solution rate of the gold, and thus lessening the period of contact during which decomposition took place. They were told that with a particular ore—that of Day Dawn—the consumption of cyanide was 4 oz., and the consumption of bromo-cyanide was an additional  $1\frac{3}{4}$  oz. But he knew more than one instance where the consumption for such tailings was 4 oz. of cyanide alone, without using any bromo-cyanide at all.

Mr. SULMAN: What would the time be in that case?

Mr. JAMES: Four to five days.

Mr. SULMAN: What we wish to make clear is that by using the  $1\frac{3}{4}$  oz. additional, you save four out of those five days, and surely that is worth while there.

Mr. JAMES, continuing, said this had been tried, and had not been considered worth that. The extra  $1\frac{3}{4}$  oz. of bromo-cyanide doubled the cyanide cost. He might almost say that extractions by plain cyanide from those same Deloro ores had been obtained as good as that the authors had stated in their paper. It would be observed that the consumption at Deloro was very heavy, without taking the bromo-cyanide into account at all; and he would like to ask the authors whether they had ever calculated how much of the  $\text{BrCy}$  was left at the end of 30 to 40 hours. He thought that the general experience was that it had all disappeared as bromo-cyanide long before that time. With regard to the zinc process, he considered the cone described in the paper a very ingenious way of getting out of their difficulties. One weak point, however, was that whereas zinc shavings would act as a filter and prevent the gold going off, Mr. Sulman had to resort to some mechanical arrangement, hung on poles around the vat, to prevent the loss of the hydrogen-buoyed bullion particles. Then the authors had made a point about the simplicity of their process in the clean-up. He himself thought it a disadvantage to the process to have to clean up once a day, or to add anything to it every two hours. The advantage of being able to run a box for a month without cleaning up was very great. As to running 400 gallons through the apparatus in an hour, he might point out that it was not at all unusual to run 6,000 gallons through a set of zinc shavings boxes in that time. With regard to the fineness in gold, the use of zinc fume was not altogether new; they had tried it before the shavings, but not perhaps so scientifically as Mr. Sulman, and they got so much zinc with the bullion that they discarded it in favour of shavings. Mr. Sulman said that the fume contained 30 per cent. of gold, but at Deloro it contained only 10 per cent., and apparently much other metal. In spite of all the difficulties of the old zinc process, they had no difficulty, in more than one place, in turning out bullion giving 960 fine, without acid treatment.

Prof. H. E. ARMSTRONG, F.R.S., regretted that the authors had not dealt more at length with the theoretical side of their process. He considered that the Society was one peculiarly fitted for discussing the higher aspects of industrial processes, and recommended the researches of Maclean, already referred to, as model investigations.

Mr. H. L. SULMAN, in reply to Prof. Armstrong's observations, said that the paper they had originally presented to the Society had undergone considerable compression, in order to bring it within the limits of the time at their disposal that evening. Why they had given more prominence to the practical aspects of the process was that when their first paper was read at the Institute of Mining and Metallurgy they were met with the objection that it was then mainly theoretical, and were advised to show what

they could do on a practical scale. They had endeavoured to follow that advice. They had since devoted their efforts mainly towards the practical details of the process, and had that evening brought the results achieved before this Society, assuming that those who had heard their former paper were practically agreed as to the validity of its theory.

As examples of practice they had given results obtained upon two entirely dissimilar types of ore, one of which had resisted every other process, and its goldfield, in spite of trials for 30 years, had remained unworked. The chlorination mill formerly put up was now a ruin. On the other hand, the bromo-cyanogen process had now been at work there for eight months past, and was economically extracting the gold; and the plant for that process was now to be enlarged. He thought that was a fair proof that they had accomplished what they had originally claimed.

Mr. Crowder, Mr. Claudet, and others had asked why they were not at work in South Africa. They were not, for this reason. The great Rand mines with their very large capital responsibilities were naturally very difficult places upon which to get experiments tried. Before they would consent to disorganise their works even to the extent necessary for practically investigating a new process, they would require previous practical demonstration of its success on a similar scale elsewhere. Therefore they had gone further afield, and as a result they now had proofs of successful working in Canada, Australia, and Hungary, and were thus in the position to answer such requirements. Mr. Louis had inquired respecting the time factor and the consumption of cyanide. Mr. James had given a partial reply to this in pointing out that cyanide would extract the gold from certain refractory ores after prolonged action, but with such a consumption of cyanide that process was not profitable; on the other hand, the bromo-cyanogen process was extracting such at a profit; shortly, cyanide was inapplicable to heavy arsenical pyritous ores, whereas bromo-cyanide was successful. On the question of the fineness of the bullion, that which they obtained at Deloro averaged from 750 to 820 fine, which he thought would be considered distinctly good from an ore of that character. He would be glad of Mr. James's opinion on that point.

Mr. JAMES: Yes, 820 fine bullion would be very good work.

Mr. SULMAN, continuing, said that they had been asked whether they had made parallel comparative tests upon vat charges running under both processes. The same argument applied to them in that case as to the Transvaal mines. They were under a contract to extract certain ores economically, and they had applied their energy to this and not to demonstrating the superiority of bromo-cyanide by lengthy comparative experiments. They had, however, already quoted the results of a large vat experiment, in which they had shown that the small amount of  $1\frac{3}{4}$  oz. of bromide of cyanogen per ton of 0.1 per cent. cyanide liquor yielded complete extraction of a tailings in 14 hours, whereas when by greatly decreasing this addition the solution approximated to plain cyanide, more than two days was necessary. At a present cost of about 2s. 6d. per pound for cyanogen bromide, that meant a charge of about 2d. per ton for this reagent, and was the sum representing the saving of the four days referred to by Mr. James.

By the use of the  $1\frac{3}{4}$  oz. of cyanogen bromide the time necessitated was reduced to 14 hours; and as the wages of a common labourer on the Murchison fields at the time was 4l. per week, he thought it would be agreed that it was well worth while to incur the cost of between 2d. and 3d. per ton for the additional bromide than to run up a far greater time bill. Mr. Claudet had said that in order to get a fair comparison in the experiment referred to, they ought to have added a weight of cyanide equal to the bromide of cyanogen added, but as that would mean an addition of only 0.005 per cent. more of potassium cyanide, this was a quantity which he thought they might very safely neglect. Mr. Claudet's other remarks has been adequately dealt with by Mr. Harland.

Mr. James and others had referred to the possibility of loss from the zinc cones, but he thought rather too much stress had been laid upon the occasional "buoyed-up"

flocks of material. When precipitation took place, two or three particles of gold-zinc couples would sometimes hang together, entangling a bubble of hydrogen gas, and would rise to the surface, discharge the bubble, and the metallic particles would thereupon at once fall back to the cone bottom. In order to prevent any possible loss from the floating over of these, they hung round the cone a narrow strip of calico, which acted as a coarse strainer; but as Mr. Picard had recently found that no such loss occurred in practice, the screen had latterly been dispensed with. He would like to ask Mr. James whether, when he talked of the rate of flow being 6,000 galls. in the ordinary cyanide process, he meant those figures to apply to one series of boxes only.

Mr. JAMES: I made use of the word "series" so that there should be no misunderstanding; I meant a series of four to six boxes.

Mr. SULMAN, continuing, said that under those circumstances the rate achieved at Deloro with one cone would compare well with the rate of liquor flow through a zinc-box. As to the question they had put forward, he could only say it had been adopted by many experts well known in connection with this subject as the most probable explanation of what actually occurred. Amongst others, Prof. Christie had practically adopted it in his well-known paper, and he believed he might quote Mr. James as also accepting it.

In reply to Mr. de Mosenthal, he was glad to say that bromo-cyanide had already superseded plain cyanide solutions on two mines, and on a third cyanide had been altogether inapplicable. As to the question of royalty, it must be a foregone conclusion that only such a royalty could be charged which would still leave a good margin of advantage in favour of the adoption of the process over and above that effected by any other process (and its royalty amount) with which it competed.

Mr. Sulman regretted that he had omitted to reply to Mr. James's question as to the interference of certain inferred decomposition products. He was pleased to say that such had not been found to occur nor to hinder them in the least, even in dealing with the highly arsenical ores at Deloro. In proof of this, they had used the same liquors there for four months straight away, and these were the same liquors that carried them through all their first more or less experimental trials. The total decomposition of the solution was, of course, accurately measured by the additional amounts of bromo-cyanide and cyanide it was necessary to use in each case in order to again produce liquor of the normal strength. As already pointed out, it was not advisable or necessary in cases of refractory ores to make the whole addition of bromide of cyanogen at once to the liquor charge pumped on the crushed material, but to apply it in two or three smaller quantities.

Dr. F. L. TEED, in further reply to the discussion, said that, with regard to the question of precipitation, it was obvious that since they could run one cone at a certain rate they could run cones in parallel series, and so without difficulty treat any quantity of material.

All alternate theories of the action of the solvent hitherto proposed involved hydrolysis and the formation of a cyanate. The fact that cyanate did not assist the solution of gold, as proved by Maclaurin, was a sufficient condemnation of such theories. The equation proposed in the paper has been accepted by Prof. Christy and Mr. Alfred James, among others.

DR. C. A. KOHN IN THE CHAIR.

## THE MAGNETIC CONCENTRATION OF SO-CALLED NON-MAGNETIC MATERIAL.

BY J. H. DARBY.

As far as the writer is aware, no account of the Wetherill concentrating machine and the material suitable for treatment has been given in this country, although in February, 1896, Messrs. H. A. J. Wilkens and H. B. C. Nitze contributed a paper to the American Institute of Mining Engineers on the subject. The writer is indebted to Mr. Wilkens for much of his information.

The title of this contribution may seem paradoxical, but it is usually understood that a substance is magnetic if it is attracted or repelled by a permanent magnet. The magnetic machine invented by Mr. Wetherill goes a step further, and is so powerful that not only can magnetic materials as usually understood be separated, but substances which apparently have no effect on the magnetic needle are readily concentrated. This opens up the economic treatment and concentration of materials that have hitherto been partially effected by washing or smelting.

Faraday and others have shown that magnetism is a property common to all substances, solid, liquid, and gaseous; but in by far the majority of cases the manifestation of this force is very feeble. Para-magnetic substances are attracted, dia-magnetic repelled. The latter represent the larger class. Dia-magnetic substances show but slight differences in magnetic capacity, but fortunately, on the other hand, para-magnetic substances vary within a wide range. Faraday's list published in 1846 gives the following metals as para-magnetic: iron, nickel, cobalt, manganese, chromium, cerium, titanium, palladium, platinum, and osmium.

Attempts have been made to determine the relative specific magnetic permeability of various substances, with more or less success; and to give some idea of how widely this varies, I may state that, according to Delesse, the magnetic permeability of—

Soft steel is .....	100,000
Magnetite .....	65,000
Siderite .....	124
Hematite .....	93 to 113
Limonite .....	72 to 113

Of the substances named, steel and magnetite alone have hitherto been called magnetic. No practical use, as far as the writer knows, has been made of the magnetic property of substances other than those which were so marked as to respond to the hand magnet, such as iron, nickel, cobalt, magnetite. It was only after Mr. Wetherill took up the matter, perfected and patented his machines, designing them after many experiments, so as to present various minerals to electro-magnets having practically a saturated field, and built in a peculiar way, that he was able to separate and concentrate many minerals that it had been previously impossible to treat magnetically.

Many attempts, more or less successful, have been made to concentrate magnetite, and amongst others I notice the elaborate plant designed and erected by Mr. Edison, at Edison, New Jersey, where he crushes down the run of a mine containing about 20 per cent. of magnetite, and by a series of machines and crushings concentrates the magnetite so that the final samples contain as much as 68 per cent. of iron, and at the same time the percentage of phosphorus

is sensibly diminished, while the waste of iron in the tails is very small.

In order to render iron ores susceptible to a magnet, recourse has been had to preliminary roasting, but this is not altogether satisfactory, as at times part of the gangue, which may contain mineral, becomes more or less magnetic, and is found in the concentrates instead of the tails. As examples of the above may be mentioned the treatment of limonite ore, suggested by Clemens Jones; the treatment of the red phosphoric ores of Alabama, by Dr. W. H. Phillips.

I cannot do better than give you in Mr. Wilkens' own words the following description: "Mr. J. P. Wetherill, manager of the Lehigh Zinc and Iron Co., South Bethlehem, Penns., found that not only franklinite, but also garnet and similar iron- and manganese-bearing minerals, could be treated by direct magnetic concentration.

"These surprising and important results were attained by utilising a peculiarly high magnetic power, applied in machines especially adapted for the purpose, and sufficient to act upon these minerals of almost infinitesimal magnetic permeability, instead of attempting (as had heretofore been done) to raise this low permeability to a point known in practice as 'magnetic,' that is, capable of attraction by a common hand magnet, or the electro-magnet heretofore employed.

"Further investigations showed that a large number of ferruginous and manganiferous minerals, such as hematite, limonite, siderite, garnet, pyrolusite, &c., besides many

Fig. 1.

ELEVATION

PLAN

WETHERILL MAGNETIC SEPARATOR No. 1.

chemical salts of iron, manganese, and chromium, were affected by this extraordinary magnetic power, and were thus adaptable to this method of concentration."

Letters patent were granted to Mr. Wetherill for his method of direct magnetic separation of para-magnetic substances of low permeability from mixtures containing the same, as well as for the machines employed to obtain this result, and these patents are now owned by the Wetherill Concentrating Company.

**Method and Apparatus.**—The machines for making these separations are of several types. Figs. 1 and 2 show a machine more especially adapted for the treatment of fine ores and for concentrations in which rich magnetite heads are more particularly sought. It has been operated very successfully on the Clinton fossil ores of the Birmingham district, Alabama.

In this type the magnetic particles are lifted away from the original mixture. The machine consists of two magnetic cores and bobbins A, and four pole-pieces B, which are pointed in the manner shown, and are adjustable by the bolts C, so that they may be moved nearer or further apart, as desired.

Fig. 2.

ENLARGED SECTION FROM FIG. 1, SHOWING ARRANGEMENT OF POLE-PIECES AND FEED-BELT.

For substances of very low magnetic permeability two of the pole-pieces are dispensed with, and a solid yoke is used instead. For substances of higher magnetic permeability, such as garnet, franklinite, siderite, &c., the yoke may be removed and two pole-pieces substituted for it in the manner shown. About each pole-piece revolves a belt D (driven by a pulley E) in the direction shown by the arrows.

The ore is fed from a hopper F by means of a feed roller G, upon a belt H, which carries it in a thin layer, say  $\frac{1}{16}$  to  $\frac{1}{8}$  in. thick, to and about the pulley J, which is of small diameter, and is upon a brass axle K, which may be raised or lowered by the adjustable bearing P. The feed can be accurately adjusted by means of a sliding shutter at the discharge of the hopper F.

The ore is thus delivered in close proximity to the space between the poles, and the magnetic particles are withdrawn and lifted up into the highly intensified field existing at this point. They are removed by the horizontal belt D, and carried into a receptacle L.

The non-magnetic tails fall from the belt H into the receptacle M.

The intensity of the magnetic attraction can be accurately adjusted by changing the distance of the feed belt from the pole-points, or by changing the distance between the pole-pieces, or finally, by changing the strength of the current.

Fig. 3 shows a machine adapted more especially for coarser sizes, material as large as  $\frac{1}{2}$  in. in diameter has been handled with it. Excellent results have been obtained by its use on franklinite ores, where clean non-magnetic tails, consisting of willemite and zincite, are sought.

In this type of machine the magnetic particles adhere to the feed-belt as it rounds the pole-points, while the non-magnetic material drops away from it. The apparatus

Fig. 3.

SIDE ELEVATION

SECTION THROUGH "B"

WETHERILL MAGNETIC SEPARATOR No. 2.

consists of magnets with cores and bobbins A, yokes B, pointed pole-pieces C, belts D, revolving about the pole-pieces in the manner shown, hoppers E, feed rollers F, and shutters G, by means of which the ore is fed in a thin layer upon the belts D. These belts travel in the direction shown by the pointed arrows, and the ore is delivered directly into the opening between the two pointed pole-pieces; means are provided by which the pole-pieces may be set further apart or closer together, as desired. Two shutters H, one beneath the point of each pole-piece, are adjustable, so that the magnetic particles which adhere slightly to the pole-pieces are carried to one side by the moving belts D, into the receptacles M and N on either side of the shutter, while the non-magnetic fall into the central space between the shutters and thence into the receptacle L.

In the third type of machine the material to be treated is fed on to a belt which passes in the horizontal plane through the gap formed between the ends of soft iron poles, which above and below the gap are encircled by powerful solenoids. Above the material so brought within the influence of the magnet, but still between the pole-pieces, another belt runs at right angles, and as the magnetic portions are lifted from the lower belt against the upper, they are carried forward by the cross belt and deposited in a hopper arranged to receive them.

"The degree of concentration desired can be regulated by changing the position of the shutters and the speed of the feed-belts, or by changing the distance between the pole-points, or by changing the amount of current through the coils."

So far, machines have been used with a capacity of from 1 to 3 tons per hour, depending upon the number of pole-pieces used, the speed of the belts, and the nature and size of the material operated on. By widening the pole-pieces and the feed-belts, the capacity can be raised; but this may ultimately reach a point where it will be more advantageous to multiply the number of machines instead of further increasing their size.

The amount of current necessary for producing the extremely intense field is comparatively small. This is due to the large area of magnetic circuit, correct proportion of the pole-pieces employed, and the almost perfect condensation at the pole-points of the vast number of magnetic lines produced in them.

For the separation of the Franklin minerals, where the magnetic heads produced consist of franklinite, tephroite, rhodonite, garnet, &c., from 3 to 8 ampères, with from 16 to 30 volts, are necessary. In the concentration of the Clinton red fossil ore from 4 to 8 ampères were used. For limonite and pyrolusite a somewhat larger current is employed, from 10 to 15 ampères giving a good separation.

"To illustrate the extreme condensation of magnetic lines at the pole-points, it may be mentioned that the current of one Daniell cell (such as is used in telegraphy) is too powerful to permit a satisfactory separation of magnetite. For this purpose its strength must be reduced by means of resistance coils, in order to prevent tangling, and allow the belts to draw the ore away from the pole-points.

"The ability to adjust delicately the magnetic intensity of these machines permits in many cases the practical isolation from one ore of several products showing a slight difference of magnetic permeability."

There is also another machine arranged with a series of magnets, where the space between the material and the magnet differs, and where the intensity of the field also differs. The strongly magnetic portion is picked out by the first magnet, less strongly magnetic portion is picked out by the second magnet, and so on. The final tails are by this method thoroughly cleaned from all magnetic heads, and the magnetic heads are graded according to their varying degrees of permeability, all being conducted in one machine.

"If two such unlike properties as magnetic permeability and specific gravity can be compared, it might be said that a much smaller difference in the former is necessary to permit a separation by magnetic means than would be required in the latter for making a water or air separation."

It would be difficult, however, to tabulate the minerals in distinct groups capable of being magnetically separated from each other, for the reason that the magnetic permeability of each mineral is, *per se*, subject to wide variations.

"Aside from the separation of several minerals from one ore, the discriminating power can be utilised for the separation of a desired quantity or quality of heads where the magnetic mineral varies in itself in permeability. For example, in the concentration of the Clinton fossil ores, the magnetic permeability of the hematite particles increase apparently with their percentage of iron, and either a small amount of high-grade heads can be produced with a low current, or a large amount of low-grade heads with a higher one. From a commercial standpoint, the exact quantity or quality which it would be advisable to produce would depend upon the increase in value of the concentrates per unit.

"The machines above described and illustrated are adapted to dry concentration. Their arrangement for wet concentration would necessitate but a slight change in some of the mechanical features."

As far as the writer knows, all iron-bearing minerals, with the exception of the sulphides, are capable of separation by the machines just described, and can be successfully concentrated. In the manufacture of iron and steel it is an acknowledged fact that, with one or two exceptions, the high-grade ores formerly used in this country are gradually becoming leaner, and are associated with a larger percentage of inert material. This has to be passed through the furnace and slagged off, consuming additional flux, coke,

and labour. The economic assembling of iron-making materials—that is, ironstone, limestone, and coke—is of great importance, and it is obvious that if an ore can be concentrated at the mine, before it has to pay railway carriage or freight, it will command a higher value, and it is sufficient to cover the cost of treatment and still leave a margin of profit, the operation will be carried out with advantage. On the other hand, it must be borne in mind that it is often necessary to reduce iron ores to a small state of division, in order to free them from the accompanying gangue, and to render them suitable for magnetic treatment. Iron ores in a small state of division have not been looked upon with any great favour by furnace managers. In America modern plants have been designed to treat the rich ores from the Mesabi district, near Lake Superior, containing 40 to 50 per cent. of very fine material, and it is an acknowledged fact that the magnificent plants in Pittsburg and Chicago treat them with astonishing results, and without the troubles which have usually been associated with finely divided ores in this country. In the writer's experience finely divided ores may be economically treated in the blast furnace under suitable conditions, and if there is sufficient pressure of blast available to force the air through the high column of materials, which in the finely divided condition offer more or less resistance to the reducing gases. The writer feels sure that with proper apparatus there will be no difficulty experienced in the manipulation of a considerable proportion of finely divided rich concentrates.

For the purpose of ascertaining how far results similar to those mentioned might be obtained by treating ores in the United Kingdom, arrangements were made with the Wetherill Concentrating Co., and subsequently an experimental machine was erected by the writer for the Brymbo Steel Co. There seems to be a possibility of concentrating the aluminous ores of Antrim, and tests have been made in this direction with some prospect of success. Should these be borne out, the heads and tails will each have a value of their own—the heads from an iron-maker's point of view, and the tails from their high percentage of alumina.

There is a mineral in Cornwall containing tin and wolframite, both of which are valuable, but the difficulty in separation has hitherto greatly reduced the market value. The mineral can be readily treated by the magnetic separator, and thus the value of the separated minerals is greatly enhanced.

The writer has recently experimented with a mineral mined in Mexico, but treated in this country. As imported it contains a large proportion of garnet associated with copper ore. It has to be brought down from the mine on the backs of mules, and between the mine and the smelting works in England has to pay a very high carriage. By passing it over the No. 1 separator, with current, pole-gap, speed, &c., suitably adjusted, as much as 40 per cent. of the imported bulk can be picked out as valueless garnet, at a small cost, and the same quantity of mineral can be conveyed by the costly method described by carrying 60 per cent. of the original weight. Samples of the original material referred to, garnet separated, and the concentrated copper ore as obtained by the writer, are exhibited.

To treat this mineral efficiently in the magnetic machine it was found necessary to grade it. Thorough mechanical separation of the garnet from the mineral was not effected until the whole passed through a sixteenth-inch mesh. It was then found advisable to divide what passed through the sixteenth mesh into two portions: that is to say, through a sixteen, and on thirty, and through thirty. These portions were then treated in the No. 3 machine, and the magnetic heads, or garnet, separated.

The assay shows that the mineral concentrates have been increased, giving—

	Cu.	Ag.	Au.
	Per Cent.	Ozs. Per Ton.	Ozs. Per Ton.
60 per cent. of mineral concentrates.	37.7	56.7	3.01
40 per cent. of garnet heads separated.	1.5	2.6	0.00

The loss in copper and other valuable minerals is therefore not as much as it would be in smelting, and the saving in carriage is very large. It must not be understood that it is necessary in all cases to "break down" a mineral as fine as the above example, but when dealing with the rare metals a very small loss in mineral has to be guarded against. The mineral in question had to be broken down for concentration by washing, and it only meant that the larger portions had to go back to the rolls before passing the magnetic machine.

The applications of this machine no doubt can be extended beyond what is known at the present time, and a hope is expressed that this incomplete communication will be of interest to the members of the Society.

#### SESSION 1897-98.

Friday, Jan. 7th, 1898.—Mr. J. Carter Bell. "The Oxygen Test for Sewage and other Effluents, as carried out in the Laboratory of the Mersey and Irwell Joint Committee."

Meeting held on Friday, December 3rd, 1897.

MR. GEORGE E. DAVIS IN THE CHAIR.

### INDIGO TESTING BY PERMANGANATE.

BY J. GROSSMANN, PH.D.

In a paper which I read in Bradford in May (this Journal, 1897, 701) I gave a *résumé* of the methods proposed for the testing of indigos. I there drew attention to a passage in Mr. C. Rawson's paper on the testing of indigos by permanganate (*ibid.* 1885, 189—191) in which he recommends those who are not well versed in chemical manipulation, and desire to determine the value of a sample of indigo to use the permanganate process, *viz.*, ordinary sulphonation and direct titration with permanganate. He says further on, "The results obtained by this method are somewhat too high, yet they give one a fairly approximate idea of the relative values of different samples under examination."

Referring to this passage I said:—

"No doubt with indigotine and the highest class of Bengal and Java the results obtained are fairly accurate for comparative purposes, but with lower qualities the results are quite unreliable and may vary 20 per cent. or more." In making these remarks I did not overstate the case. In the discussion which followed, Mr. Rawson passed over my criticism on the direct titration with permanganate and went on to say that *after* purification there was in his opinion no better method of estimating indigotine in indigo than by means of potassium permanganate, thus shifting his ground by introducing another test which was neither the one which I criticised nor another proposed by Mr. Rawson and known as the salting-out test.

Again, in summing up the merits of the different tests which he has investigated, Mr. Rawson says:—

2. The permanganate method affords a quick and ready means for the approximate valuation of indigos; but as substances soluble in dilute acids are, at the same time, more or less acted upon, the results obtained are somewhat too high.

3. If the solution of indigo be saturated with sodium chloride the colouring matter is thereby precipitated. When the precipitate is washed, dissolved in dilute sulphuric acid and extracted with potassium permanganate, results are obtained which for all practical purposes are trustworthy and reliable. Indigo red and indigotine are simultaneously estimated by this modified process.

Now I quite agree with Mr. Rawson's opinion about the modified permanganate process, under 3; if used in conjunction with my dyeing test it gives results by which no buyer of indigo can possibly go wrong. But as regards the direct method and his remarks on it I entirely dissent on two grounds. In my opinion persons not well versed in chemical manipulation have no business with chemical analysis. In gravimetric analysis it is usual for a competent analyst to examine whatever precipitate he has weighed to make sure that it is pure and the actual substance he wanted. In the case of volumetric tests, where such subsequent verification cannot be made, chemists who employ them should be, if anything, still more competent. An incompetent person using the direct permanganate test might describe a mixture of sawdust and iron filings coloured blue with some aniline colour as a high class Bengal indigo. My second ground of objection is that there are only two kinds of methods which should be used in analysis, *viz.*, such methods which are correct within almost scientific limits and such methods which though not being absolutely correct have a constant error. Thus a method which in each case would only give, say, 95 per cent. of the actual quantity present would be quite admissible for commercial work, as by dividing the result by 95 the test would be quite accurate. But a test which showed at various times from 80 to 95 per cent. of the actual contents would be absolutely worthless, as whatever result were obtained would convey no information. Sometimes it might be right other times 5, 10, 20, or more per cent. wrong. The direct permanganate test is of this type. Take Mr. Rawson's own figures and compare them with each other; the following table will show you that they differ from the modified test by from

Per Cent. of Indigotine by Direct Permanganate Test.	Per Cent. of Indigotine after Precipitation with Salt.	Percentage Error by Direct Permanganate Test.
76.32	73.82	3.40
76.05	73.27	3.80
66.71	63.50	5.05
62.85	57.74	8.85
62.32	57.30	8.76
62.66	57.50	8.97
50.04	44.90	11.50
47.15	43.30	8.90
47.15	42.00	9.90
39.50	37.40	5.61

3.4 per cent. to 11.5 per cent. In other words, by using the direct permanganate method you may be able to judge within 6d. per lb. what an indigo is worth. It does not require a chemist to do that; any judge of indigo could come nearer the truth by the appearance of a sample.

My own experiments, however, show that by this test you cannot even tell to a shilling per lb. what indigo is worth. The following table gives the results of a number of samples of high class indigos tested by the direct and the modified permanganate process:—

Per Cent. of Indigotine by Direct Permanganate Test.	Per Cent. of Indigotine after Precipitation with Salt.	Percentage Error by Direct Permanganate Test.
69.1	67.8	1.9
53.4	49.8	7.2
62.9	59.4	5.9
62.1	59.0	5.2
61.6	62.0	4.2
53.4	48.9	9.2
50.0	55.0	7.2
62.9	58.6	7.3
68.2	62.0	10.0
69.4	61.8	7.1
59.7	55.3	7.9

The difference in the tests of these varies from 1.9 per cent. to 10 per cent.

In the lower qualities, the difference is considerably more marked, as the following table will show:—

Per Cent. of Indigotine by Direct Permanganate Test.	Per Cent. of Indigotine after Precipitation with Salt.	Percentage Error by Direct Permanganate Test.
43.2	39.7	8.8
42.0	35.8	17.3
41.9	36.2	15.7
47.2	45.0	1.9
46.3	43.7	5.9
44.2	43.3	2.0
34.5	33.6	2.7
45.9	44.1	4.1
43.3	40.1	8.0
43.7	42.4	3.1
43.3	39.3	10.2
45.4	44.5	2.0
37.6	36.2	3.9
37.2	27.6	31.8
46.3	43.2	7.2
39.7	35.8	10.9
38.0	31.1	11.3
41.9	39.2	6.9
43.1	38.8	11.1
34.5	33.6	2.7
45.8	44.1	3.9
38.8	37.0	4.9
42.4	38.0	11.6
44.2	41.9	5.1
50.1	44.4	12.8
42.1	40.8	3.2
48.1	40.5	18.7
47.7	45.0	6.0
39.2	25.6	35.0
48.1	45.5	5.7

This table represents the tests of Kurpahs, Ondes, and similar classes of goods, and I have given a large number of samples because these qualities are largely used in Lancashire for dyeing cotton yarns and piece goods. The tests are from 2.4 per cent. to 34.8 per cent. too high, and invariably against the buyer. They show conclusively that the direct permanganate test is worthless. The tests which I have given are not selected samples, but have been copied at random from my laboratory notes.

There is one more variety of test with permanganate which I may discuss so as to complete the subject; it consists in extracting the sample of indigo in succession with weak acid and caustic soda or ammonia, then drying and dissolving in sulphuric acid and titrating direct with permanganate. The results are disappointing and such as do not warrant me to recommend this method.

Per Cent. of Indigotine by Direct Permanganate Test.	Per Cent. of Indigotine after Extraction with Acid and Caustic Soda.	Percentage Error by Direct Permanganate Test.
48.0	48.1	0.0
48.0	47.1	1.9
46.8	45.1	8.6
48.1	44.9	7.8
48.8	48.7	1.8
45.6	41.9	8.8
49.6	46.8	6.0
43.7	42.1	4.8
57.0	53.3	6.9
62.5	61.8	1.0
70.4	70.4	0.0
74.4	71.6	3.9
66.5	62.5	6.4

From the table which I have given it will be seen that although in some cases the results are exact, in others they are nearly 9 per cent. wrong, and against the buyer.

The conclusion which I draw from these experiments is that the only permanganate test which should be used for commercial testing of indigos is the one proposed by Mr. Rawson in which the sulphindigotate is previously thrown down with salt. This method, save in exceptional cases, gives reliable results; in conjunction with my dye test it is perfectly reliable. I may also add that the instructions given by Mr. Rawson for dissolving the indigo in sulphuric acid should be scrupulously adhered to, otherwise the results will be unsatisfactory.

#### DISCUSSION

Dr. GERLAND said, of the chemical substances which were formed they had no idea. The quantity of oxygen consumed certainly did not agree with the formation of isatin or any other known compound; but, on the whole, he agreed with Dr. Grossmann as to the testing of indigo. He had often tried salting out. If salt were added to saturation, and the solution allowed to stand overnight, all the indigo had gone out of it, and it was left perfectly clear. If, on the other hand, they followed Rawson's advice, and precipitated with a certain amount of salt, avoiding saturation, then came the difficulty of making allowance for the indigo afterwards left in solution, which was unsatisfactory. The salted-out indigo sulphate did not show the disappearance of the blue colour sharply enough to use it for the hydro-sulphite titration.

Dr. GREEN referred to W. Brylinski's paper on methods of testing indigo given in *Monit. Scient.* (this Journal, Nov. 1897, 938), in which preference was given to Engler's method.

Dr. GROSSMANN, in reply, said that in using Rawson's salt test it was necessary to use the exact quantities recommended by Mr. Rawson. If Dr. Gerland used more salt than Mr. Rawson recommended, he would get wrong results; but as Mr. Rawson had examined the subject thoroughly, and worked out the right proportions, there was no reason why anyone should deviate from the quantities which he gave. The salting-out method was a very reliable one. In a few exceptional cases it might not give accurate results, but when used in conjunction with the dye test it was absolutely reliable. The paper referred to by Dr. Green had escaped his notice, but, so far as he could learn from Dr. Green's remarks, there was only this difference, that Mr. Engel proposed a vanadium volumetric test in conjunction with a dye test, and he advocated Rawson's salting-out permanganate test in conjunction with his dye test.

#### STEAM, GAS, AND ELECTRICITY, AS SOURCES OF ENERGY IN CHEMICAL WORKS.

By F. H. EDWMAN, D.Sc., F.R.S.E., ASSOC. INSTN. C.E. AND M.E., AND M.I.E.E., ETC. ETC.

Power in chemical works does not occupy so important a position as it does in textile industries, where the whole of the transformation is effected by mechanical power. In chemical works it is principally confined to subsidiary

operations, such as grinding and pulverising raw materials, working pumps for the purpose of lifting the various liquids, compressing air or other gases, mechanical furnaces, grinding, centrifugal drying machines, making boxes or barrels, actuating cranes, or in the form of locomotives for haulage in the yards.

In the carrying out of any works with which I have had to do I have always endeavoured to avoid mechanical operations; and when these were necessary, the machine was made as simple as possible. Chemical works abound in dust, dirt, gases, or liquids which injure machinery, wherein lies the difference between them and a textile factory. It is thus advisable to use the very simplest forms of engine which can stand the rough wear and tear to which they have to be subjected.

Chemical works usually cover a large area of ground, and it is not possible to centralise the power, because operations are rarely simultaneous, and often far from one another, and small independent engines have to be relied on.

Even under the best conditions the steam engine is a wasteful machine. The source of loss arises in many parts. First of all there is the inefficiency of the boiler itself. The boiler ought to be as simple as possible, because it is usually tended by unskilled labour, has to work night and day, and is more liable to strain by continuous working than if it could be stopped and attended to oftener.

In my opinion there is no boiler equal to the two-flued Lancashire. It is not as efficient as the locomotive type, or even the externally-fired tubular type; but it is the simplest, requires little attention, is easy to clean and repair, and will burn—if the draught is properly regulated and the size of the grate area properly designed—with every kind of fuel. For an internally-fired boiler, in charge of a skilful fireman, hand-firing will meet all the requirements, but in large works it is advisable to have mechanical stoking, because there is the same efficiency at all hours, and this more than compensates for the extra expense of the mechanical stokers, which, moreover, tend to the prevention of smoke, and an increased economy. Mechanical stokers are of two kinds—coking stokers and sprinkling stokers. The coking stokers are fed continuously at the front, and the evolved gases pass over the hot fuel at the back of the grate, and this I have found to be the best where the work is continuous.

Mactear furnaces in the ammonia-soda process, or the salt pots and furnaces in the Le Blanc process, which require a continuous flame, cannot be worked efficiently if it is necessary to consume all the fuel, and hence where the works are large enough it is advisable to mix the unburnt fuel from these furnaces with a small portion of good slack, and then use it for steam raising with a forced draught either by use of the fan, or, what is simpler still, the steam jet properly arranged, which makes the furnace practically into a blacksmith's hearth.

A pound of ordinary Lancashire slack or Burgy coal will evaporate from 8 lb. to 9 lb. of water when the boilers are free from scale and the water sent in at near boiling point.

A Lancashire boiler fitted with an economiser almost equals a tubular one, but the latter does more work in the same space, and though it costs more to keep up it saves expenditure in plant.

With an efficient boiler and first-class engines the cost of delivering power at the fly-wheel shaft amounts to 10*l.* per indicated h.p., or, say, 5,000*l.* for a 500 h.p. engine. This includes a moderate price for the area of land upon which the plant stands. An average pound of hydrogenous coal will give about 14,500 heat units, and about 10,800 out of the 14,500 are delivered as steam to the cylinder. If we allow about 8 per cent. for ash we may say that 1 lb. of coal will practically yield about 10,000 heat units. This represents about 7,720,000 ft. pounds of energy, and if this could all be utilised in a steam-engine, this 1 lb. of coal would represent roughly 4 indicated h.p., working for one hour, and this would be about a  $\frac{1}{4}$  lb. of coal per indicated h.p. per hour. Unfortunately no steam-engine will accomplish this. The very best marine engines consume about 2 lbs., while ordinary condensing engines use from 3 to 3½ lbs. of coal, taking 1 lb. of coal to represent about 9 lb. of water evaporated. The best triple expansion engines

measured by the quantity of steam which they use, consume from 12 lb. to 14 lb. of steam per indicated h.p. per hour. Compound condensing engines use from 15 to 18 lb. of water; single cylinder condensing engines from 20 to 25 lb., and high pressure engines, varying with the steam pressure and the size of the engine, from 20 to 50 lbs. Some of the numerous engines that are found in chemical works doing the pumping under the ordinary conditions of open air and other disadvantages, and so frequently of such a small size, would be found to use even more than this.

If we raise steam with 1 lb. of coal with the very best appliances our results would be something as follows:—

	Per Cent.
Loss by imperfect combustion, radiation from the furnace, and heat carried up the chimney .....	20
Heat lost by radiation from the boilers, pipes, cylinders, &c. ....	2
Carried away into the condenser or sent out as waste in the exhaust steam, if a high pressure .....	63
Converted into indicated h.p. in the cylinder .....	15

Now, as we have no engine that will work with 1 lb. of coal per indicated h.p. per hour, it means that we do not and cannot at the present moment utilise 85 per cent. of the energy in the coal.

In large chemical works, power has to be distributed over miles of pipes exposed to the condensing action of the air, and hence a very large percentage of inefficiency must be added to that which has already been mentioned. I doubt in many of our small engines whether we actually use 5 per cent. of the power which was originally in the fuel.

Now comes the question of cost per indicated h.p. per annum. From a series of experiments with a compound condensing engine of 500 h.p., the cost of which was, roughly, 5,000*l.*, the cost came out as follows:—

	£	s.	d.
Interest on plant, 10 per cent. ....	500	0	0
Wages .....	160	0	0
Cleaning and repairing boilers and brickwork .....	90	0	0
Oil, grease, boiler composition, &c. ....	80	0	0
Repairs, and keeping up of engine, including packing .....	100	0	0
Rate, taxes, and insurance .....	100	0	0
Sundries .....	50	0	0
	1,080	0	0

The boilers were Lancashire two-flued boilers working at 100 lb. pressure, which is as high as I should recommend for chemical works. The boilers were 8 ft. diameter by 30 ft. long, with five tubes in each flue and a set of two Green's economisers.

This gave for power, without water or fuel, about 2*l.* 3*s.* 3*d.* per indicated h.p. per annum. The coal was good slack, 6*s.* 8*d.* per ton, delivered in the firing floor; and the amount of coal consumed, including banking and other purposes connected with the power, but not including the heating of the works, which was supplied from a separate boiler, gave 4½ lb. of coal per indicated h.p. per hour; the ashes and banking represented about  $\frac{1}{4}$  lb., so that the efficiency of the engine was about 1 lb. per horse. The coal cost about 2*l.* per indicated horse, per annum, making a total cost per h.p. per annum, 4*l.* 3*s.* 3*d.*. This is about  $\frac{1}{4}$  of a penny per indicated horse per hour on a working week of 56½ hours per week, and 50 weeks per annum. The engine under test conditions gave under 2 83 lb. of coal per indicated h.p. per hour, measured by the actual steam used, as calculated from the indicator diagram; but the tests were taken of the cost based on five years working. This was working the ordinary factory hours; and in chemical works where 24 hours are worked, there is not the banking to take into account; but I very much doubt whether an equivalent of steam delivered to the engines of any chemical works costs less than this.

Steam is not a good vehicle for obtaining power, because it can never be a perfect gas unless absolutely dry; and the moment it begins to expand—which it must do if worked economically—it ceases to be a dry gas.

I thought at one time of using producer gas. I put down producers, but found that to keep up a constant supply of gas it required a series of producers rather than storage space in a gas-holder as this enabled me to equalise the flow of the gas, and utilise the heat of the gas at the time of its generation in the producer. I also found that it was useless in two-flued boilers, as a large portion of the efficiency of the boiler arises from radiation from the fuel, whereas the gas flame was non-luminous, and its efficiency as a steam-raiser was greatly reduced. If complete combustion were not attained and the flame thereby rendered luminous, it deposited on the surface of the boiler enormous quantities of soot, which seriously interfered with the efficiency of the heating surfaces. If the flame was made to impinge on refractory material, such as filling the flues partially with bricks stacked so as to leave interstices between them, the efficiency was increased. But my experiments led me to the conclusion that for the use of gaseous fuel, tubular boilers were absolutely essential, so that the whole of the flame might be brought into intimate contact with a large and as thin an absorbing surface as possible.

For ordinary steam-raising I believe the present method of using solid fuel is far the best and the most economical. Where gas is a by-product it practically costs nothing. If gas is to be used as a source of power, we must look for its utilisation to the gas-engine; and already in this direction results have been reached which exceed in economy the use of steam.

In first-class gas-engines an indicated h.p. has been obtained on a large scale with rather less than 1 lb. of coal per hour, which is about 50 per cent. more economical than the best steam-engine. Gas-engines, however, are complicated and intricate, and this renders them unsuitable for chemical works, although if kept in a separate building and then worked with a mixture of water gas and producer gas, I believe that they might come in at far less than the cost of steam. On the other hand, in nearly every part of a chemical works, steam is required for purposes other than power, and the pipes that convey the steam can readily be drawn on for power. For power alone the gas-engine is a most efficient machine, especially for the production of an electric current. I myself have obtained power in this way at less than half the cost of steam, and with a 200 or 300 h.p. plant it is possible to produce an indicated h.p. at a cost of not more than 30s. per annum. The cost of a gas plant and gas-engines complete may be taken at about 12*l.* per indicated horse, so that the original cost is about 20 per cent. dearer than a steam plant, but it is 50 per cent. more efficient, so that the first cost need not be considered. Thus a 500 h.p. plant for steam being 5,000*l.*, a similar gas plant would be 6,000*l.*, but a saving of only 2*l.* per h.p. per annum would repay the extra outlay in 12 months and represent a saving of 1,000*l.* per annum ever afterwards. This is quite as low as any figures I have been able to obtain with regard to water power, either here or on the Continent. We have so little water power in this country that it is hardly necessary to discuss its merits, but it becomes an item to be taken into calculation when electrical processes are to be used and power becomes a considerable item.

I understand that in Germany an indicated h.p. can be produced by water at 50 marks per annum, and in some other parts of the Continent and in America at 2*l.*; but water power is often distant from the centre of distribution, and also from places where coal can be obtained, and thus the cheapness of the power is more than balanced by increased cost of fuel and carriage.

In chemical works, electric distribution is almost impossible. Dust and gases have great effect on conducting wires and electric motors. I have used lead-covered wires with a coating outside, and yet they were eaten through in a short time; and, except where motors can be enclosed in special rooms or boxes and conducting wires kept out of reach of corrosion, electric distribution of power is not suitable for such works. With electric chemical processes the conditions are different, but I shall not deal with them to-night, as possibly they may form the subject of a future paper.

Electrical distribution can best be applied in chemical works to lighting. You can obtain at least twice the quantity of light by the arc lamp than by burning gas or even Wells' lights. To compete with steam as a motive power, electricity must be supplied at not more than  $\frac{1}{4}$  p. per Board of Trade unit, or half this cost to compete with gas.

### CHAIRMAN'S ADDRESS.

#### THE UNORGANISED FERMENTS, OR ENZYMES CONCERNED IN THE BREWING AND DISTILLING INDUSTRIES.

BY JAMES O'SULLIVAN, F.R.C.S., F.R.S.

WHEN food is consumed by animals it is not, as is well known, always in a condition suitable for absorption, and before this can take place it must be changed by the complex process of digestion in which each organ of digestion performs its allotted functions. The digestion in highly organised animals, of which we are able to speak with certainty, is entirely external or in other words, it takes place outside, for the alimentary canal is simply a continuation of the external surface. Digestion also takes place in the vegetable kingdom, and, although there are instances of external digestion, interior or interstitial is the most prominent. When we come to the germination of seeds and the growth of bulbs and tubers we have exclusively only to deal with interstitial digestion.

The varied food consumed by man requires for its digestion seven or eight soluble ferments, or enzymes.

In the brewing and distilling industries the enzymes which bring about the solution or digestion, of the substance of a seed, play a most important rôle and I propose in this address to consider what, from a practical point of view, is known of their action.

A grain of barley, the seed almost exclusively used in the industries mentioned, consists of embryo and endosperm, which are, broadly speaking, composed of starch, sugars, cellular matter, albuminoids, cellulose, fat, and mineral matter. These reserve materials, which are mainly situated in the endosperm of the grain, are almost all insoluble. Now the young plant in order to avail itself of this insoluble material must either be provided with, or it must provide for itself, a means of rendering it soluble for use during its growth.

It appears that it was known in the early years of the present century that wheat contained a soluble ferment possessing the power of dissolving starch. Kjeldahl (1879) and Lüntner and Eckhardt (1889) studied the properties of diastase found in barley, and compared its action on soluble starch with that of malt-diastase. In 1890 (Trans. Lab. Club) I found this ferment in the endosperm of barley, maize, rye, wheat, and oats. Lüntner and Eckhardt found

that in its hydrolytic power barley-diastase was more active at low temperatures than malt-diastase, which showed a difference between them. This information about the hydrolysis of "soluble" starch did not, however, explain how the starch granules (comprising about 50 per cent. of the total weight of the grain) were made soluble during the germination of the barley. Brown and Morris ("The Germination of some of the Gramineæ," J. Chem. Soc. 1890) named the less active diastase of barley "diastase of translocation." It does not liquefy starch paste, nor does it erode starch granules.

The endosperm of barley is made up of a network of cellular matter which encloses the starch granules. It follows from this that as the hydrolyst in the ungerminated grain does not dissolve the starch granule that some active agent must come into existence before the starch of the endosperm can be dissolved. The cellular structure in which the starch granules are enclosed must itself be dissolved. That this does take place has been shown by Brown and Morris who have demonstrated that the cellular network enveloping the starch granules is dissolved by diastase, prepared from air-dried malt after the manner in which diastase from kiln-dried malt was prepared by C. O'Sullivan (J. Chem. Soc. 1884). The body thus prepared has been proved to possess cyto-hydrolytic as well as amylolytic properties. It is well known that the starch granules of barley are eroded and dissolved during germination.

As the diastase "translocation diastase" already present in the barley, does not possess the power of eroding starch granules the agent which does this must be produced during germination. I proved (Trans. Lab. Club 1890) that on the third day of germination there is present in the endosperm of germinating barley sufficient diastase to completely dissolve the starch when digested at a temperature of 65° and this was observed prior to any visible growth of the embryo.

Baranetzkey in 1878 found that the starches of grain were eroded by malt diastase. It is interesting to mention that malt diastase has not this action on potato starch (C. O'Sullivan, J. Chem. Soc. 1876) which indicates that the diastase of the germinating potato differs from malt-diastase.

Brown and Morris established that the diastase produced during germination is a secretion of the absorptive epithelium of the embryo and have named it "diastase of secretion."

Here then are the two enzymes which play the most important part in rendering soluble and changing the material of the grain, to the required extent, in the preparation of malt. One a cyto-hydrolyst possessing the power of dissolving cellular matter (cellulose) the other an amylolytic-hydrolyst possessing the power of dissolving starch.

When barley is germinated the proteids which are insoluble are made soluble. However, at the present time, we are not in a position to speak more definitely about a proteid-hydrolyst than to infer that a somewhat similar process of solution of the proteids takes place to that of the carbohydrates.

I have proved (Trans. Lab. Club, 1890) the presence of invertase in the acrospire and rootlets of the embryo barley plant, which is unquestionably concerned in the assimilation of the metamorphosed constituents by the plant. This observation is, I believe, highly important, supported as it is by evidence which I have at hand of the presence of invertase in all portions of the gramineæ from seed to plant.

The enzymes we have up to this considered are only treated from the point of view of the production of malt, which is the first and not the least important of the processes involved in the brewing and distilling industries.

The diastase of secretion plays another and a most essential part in the solution of the starch of malt in what is called the "mashing process."

C. O'Sullivan in a series of classical papers (J. Chem. Soc. 1876—79) published the results of his work, "On the Action of Malt Extract on Starch," and showed that when starch is dissolved by malt extract—diastase—there are

produced maltose and dextrines. Since 1879, although he has been active in other spheres of research, he has ceased to contribute to this subject, which is very much to be regretted. However, the method of following up the transformation of starch was established by him, and has led to numerous and valuable contributions on the subject.

Hertzfeld in 1879 proved the presence in starch transformations of a body to which he gave the name of malto-dextrin, a combination of a maltose group and two dextrin groups. In the same year Brown and Heron (J. Chem. Soc. 1879) published on this subject and corroborated in the main the results of O'Sullivan.

Brown and Morris in 1890, from a vast amount of work, supported by practical observations, put forward the following hypothesis of the solution of starch by diastase:—That when starch is dissolved by diastase there are produced maltose, free dextrin, and varying types of malto-dextrin or amyloins.

Maltose is the final product of the action of diastase on starch, and the free dextrin is only hydrolysed very slowly (C. O'Sullivan, J. Chem. Soc. 1876, 127), while, according to Brown and Morris the amyloins, which are produced with the free dextrin, are rapidly hydrolysed to maltose.

I have not drawn a distinction between the brewing and distilling industries as to the use made of the enzymes. There is, however, a difference. In brewing, the aim is to restrict the action of the diastase to suit the requirements, whereas in distilling the object is to obtain its highest action, so as to produce the maximum amount of fermentable sugar.

I give in the following table a scheme of the enzymes concerned in the brewing and distilling industries up to this stage of the process—the production of a "fermentable wort."

Table of enzymes which we know are concerned in the production of brewers' and distillers' wort:—

Origin.	Enzyme.	Properties.
Barley .....	Diastase of translocation.	Does not erode starch granules or liquefy starch paste, but dissolves "soluble starch."
Germinated barley (malt).	Cytase Cyto-hydrolyst.	Dissolves cellular matter and is rendered inactive on heating. Therefore is not present to any extent in kiln-dried malt.
" "	Diastase of secretion (Amylo-hydrolyst).	Liquefies and hydrolyses starch paste at all temperatures up to 80°.

The distiller does not dry his malt at as high a temperature as the brewer, nor does he boil the wort prior to fermentation, in fact his object is to obtain the highest possible diastatic action. The diastase of the wort is present during the alcoholic fermentation in the distillery, and continues to hydrolyse the non-fermentable starch products of the wort to fermentable maltose. In consequence of the presence in distillers' wort of the free dextrin, which is only slowly hydrolysed, there is almost invariably to be found in distillers' "wash" from 18 to 20 per cent. of the original malt solids unfermented, of which 5 to 6 per cent. is dextrin, and apparently maltose.

Although brewers' and distillers' yeast contains the well known enzyme-invertase, which inverts cane sugar, we are not able to say what function this fulfils in the fermentation of malt wort, other than the inversion, prior to fermentation of the small amount of cane sugar usually present.

In the fermentation of cane sugar it is first hydrolysed to dextrose and levulose, and these sugars are always present in solutions of cane sugar undergoing fermentation. Maltose, which chiefly composes the fermentable sugar of wort, is fermented without its hydrolysed product being noticed; it is in fact directly fermented. This led many to look upon the fermentation of maltose as being analogous to the fermentation without previous hydrolysis of cane sugar by *monilia candida*. Fisher (Ber. 1894, 271) has, however, shown that from air-dried brewers' yeast a maltose-hydrolysing enzyme can be extracted, to which he gave the

name "beer yeast-glucose." This work of Fisher in establishing the presence within the yeast cell of a maltose-hydrolysing enzyme, together with what we already know of the absence of its hydrolysed product, dextrose, during fermentation, and of the hydrolytic functions of yeast, as shown by me (J. Chem. Soc., 1892, 593) adds considerable weight to our belief that hydrolysis and fermentation takes place within the yeast cell.

The following are the enzymes which we know are concerned in the fermentation of a brewer's wort:—Invertase and beer yeast-glucose, and to these in the case of the distillers' wort we have to add diastase.

We must not leave the question of translocation diastase without referring to another and important part it plays in the brewing industry. In 1878 Baranetzky drew attention to the fact, which he observed, that diastase was present in all portions of plants in which he looked for it. He found it in seeds, tubers, stems, and in the leaves. Brown and Morris (Trans. Inst. Brewing, 1893) showed that dry hops which are added by brewers to finished beers contain diastase, which has the power of hydrolysing to maltose the amyloins, and the free dextrin in beer thus supplying a fermentable sugar for continuing the after or cask fermentation.

I have not given analyses of these enzymes, although there are many published, nor have I considered their properties, only so far as these relate to the technical processes in which they are concerned.

All analytical evidence proves that they contain nitrogen, and are not albuminoids, while it also shows the difficulty which attends their preparation in a pure state. It is needless to say that until an amorphous substance is proved to be homogeneous, its analysis is not of much use, and to add to this we have in the case of enzymes the greatest difficulty of all, *viz.*, "that of proving their purity without altering the properties upon which their designation depends." We are forced to the conclusion that we do not know with certainty the composition of these most important products of life.

#### DISCUSSION.

Dr. J. J. Sudborough said that two diastases had been mentioned in the paper, namely, that of translocation and that of secretion. It was a matter of regret that these two evidently distinct substances should have received the same name. If one could be altered it would be a desirable thing to do in order to prevent confusion. In a recent article in the *Berichte* (1897, 30, 2289) Wroblewski has shown that the ordinary diastase of malt as obtained by Lintner's method can be separated into two distinct compounds, namely, a solid carbohydrate, which on hydrolysis yields arabinose, and a proteid-like substance, which alone has any diastatic action. Wroblewski has suggested that the enzymes are closely related to albuminoids, and are probably to be regarded as a sub-group of the proteids.

Did the Chairman know whether any other chemists besides Stavenhagen had repeated Buchner's work on the isolation of zymase from yeast (*Ber.* 1897, 30, 117, 1110, 2422; this *Journal*, 1897, 548 and 1030); and if so, with what results? If Buchner's work were confirmed, it would certainly be one of the most important discoveries in connection with fermentations that had been made for many years, as it seemed to indicate that fermentations induced by organisms were really fermentations by means of enzymes. Was not the enzyme, described by Mr. O'Sullivan as beer yeast-glucose, termed maltase by Fischer, who first isolated it?

Dr. F. Clowes (the President) had recently spoken with a high authority on the work of Buchner, who seemed to look upon his results as not proved. It was remarkable that no confirmation of the work had appeared from other investigators, and that the changes producible by other organised ferments besides yeast had not been shown by Buchner or others to be producible by an unliving enzyme derived from the ferment itself. He was not aware that Buchner's work had been either confirmed or extended in the way referred to.

The CHAIRMAN in reply said that, as the diastases prepared from barley and malt had been observed to

possess different properties, Brown and Morris gave them names which showed at once their origin. It would be advisable in order to avoid confusion, when speaking of a preparation of diastase, to state its source, as for example, barley-diastase, malt diastase. Malt-diastase, a body prepared from maize-malt, in a similar way to barley or malt-diastase, possessed the power of hydrolysing maltose to dextrose (Geduld's glucose). Fisher had pointed out the importance of indicating the origin of enzymes, and when he discovered that air-dried beer yeast yielded a maltose hydrolysing enzyme he called it beer yeast-glucose.

It had been known for some time that malt diastase as usually prepared, contained a nitrogenous body and a carbohydrate, but it had been found most difficult to obtain these in a pure state. Wroblewski's work was certainly an addition to our knowledge, but it must be considered doubtful whether he had been dealing with a pure diastase; his numbers for nitrogen in his preparations appeared to show that he was not; his analysis in fact were as varied as any yet published. He was not aware of any English chemist having repeated Buchner's work. However, Stavenhagen and Prutzkow did not confirm Buchner's sensational announcement, and it was highly improbable that his work would ever be corroborated.

#### REFLUX CONDENSERS.

BY J. J. SUDBOROUGH, F.R.S., D.S.C., AND  
M. F. FEILMANN, B.Sc.

Mr. FEILMANN explained that in some of their work the authors required to boil ethereal and alcoholic solutions for several hours on the water-bath, using a reflux condenser. With the ordinary Liebig and bulb condensers they always found that the large amount of moisture deposited on the outer surface trickled down over the cork and was liable to permeate into the flask. In order to avoid this condensation on the outer surface the authors suggested the apparatus (Fig. 1), which had been constructed for them by Messrs. George, of Birmingham and London. In this apparatus the cold water was made to pass through the inner tube and the ether or alcohol vapours were condensed in the annular space between the inner and outer tubes. By this means the outer surface of the condenser was kept warm and the deposition of moisture avoided. For use with ether they had found the apparatus a great improvement on the usual form of condenser, as in addition to the cold water surface it also utilised the cooling action of the air, and condensation was therefore very complete.

For high-boiling liquids the authors suggested the following form of apparatus (Fig. 2), as in the apparatus first described there would be a great strain on the inlet tube (a) through extremes of temperature, causing a liability to crack.

FIG 1

FIG 2

FIG 3

The authors, of course, claimed no originality in principle for the apparatus proposed by them, as an inner cold-water condensing surface was already in use in the well-known metallic Soxhlet condenser.

#### DISCUSSION.

MR. JOHN GOLDING said that being in Copenhagen last summer, he was shown by Dr. Storch the apparatus which he used, and which, although different, yet embodied the same principle as that described by the authors. There were 50 of these appliances going in the laboratory in two sets of 25. They were all working with ether, and although he smelt for it, he could detect none escaping. An ordinary combustion tube some 31 cm. long and 3 cm. internal diameter was drawn out to fit the cork of the boiling flask. The condenser, which was made of thin white metal, was 2½ cm. in diam. and about 7½ cm. long, and rested on the top of the tube by the projecting rim of the cover as shown in Fig. 3. This left an annular space of ¼ cm. between the condenser and the tube. This must be very cheap to make. He might mention that the oil cakes were extracted, after drying in a current of hydrogen or coal gas to prevent the oxidation of the oil which would otherwise take place. The cake, in the form of a cylinder, was kept away from the sides of the tube by projections in the interior of the latter, made by depressing the glass from the outside, as shown at *a* and *b* in the figure. This left a space which allowed the ether vapour to freely circulate round the cake.

MR. R. M. CAVEN said that there was considerable loss with the ordinary Liebig condenser when working with ether, and if the apparatus described prevented this it would be a decided advantage.

The CHAIRMAN remarked that the great difficulty with all these condensers was to get the ether to permeate the whole of the substance under treatment. The drop only went through the middle of the mass leaving portions at the sides insufficiently acted upon.

MR. J. GOLDING : Dr. Storch found no difficulty of the kind with his arrangement. They were left to act for four hours and could be left for six or eight.

The CHAIRMAN said that was a long time, but he had found an hour not long enough.

MR. G. J. WARD suggested that to prevent the drop always falling in the same place the bottom of the condenser might be made flat.

DR. SREBOROVICH, or it might have a number of glass balls attached to the bottom.

MR. TROTMAN said it was certainly necessary to have an apparatus that could safely be left to look after itself. For instance, he had known a case where after returning from lunch the ether flask was found dry.

PROF. CLOWIS said that in Dr. Thorpe's London laboratories they had refrigerating arrangements so that they could supply ice water to the condensers. Such a plan necessarily reduced the losses very considerably. Closing the top of the condenser he also thought would prevent loss as there must be diffusion by contact with the atmosphere.

MR. FLEHMANN replied that they had boiled ether vigorously under it and found very little smell at the top.

The CHAIRMAN suggested that if the inner tube (Fig. 3) instead of being plain had a number of constrictions the apparatus would probably be found to be still more efficient.

*Meeting held at the Midland Hotel, Derby, on Wednesday, December 15th, 1897.*

MR. G. J. WARD IN THE CHAIR.

### THE RECOVERY OF SULPHUR FROM HYDROGEN SULPHIDE.

BY E. J. R. CARLLEY, F.R.S.

I.—In the manufacture of sulphate of ammonia from gas-liquor and in other chemical operations, sulphuretted hydrogen is evolved. It is not permissible to send it into the atmosphere through high chimneys, except after burning

and the products of combustion being considerably diluted, the Alkali Works Regulation Act fixing the limits of acidity for such gases from chemical works at 4 grains per cu. ft., which must on no account be exceeded.

Various methods have been adopted from time to time to get rid of this noxious gas, and, at the same time, obtain the sulphur in some useful form, either combined or in the free state. One of the earliest was to burn it in air, sending the products of combustion into sulphuric acid chambers.

It is at once evident that 33 per cent. of the air employed is used for the conversion of the hydrogen into steam, and consequently the corresponding amount of inert, useless nitrogen, which only takes up space and diminishes the working capacity of the chambers, has to be admitted into them. This, together with the carbon dioxide present, so reduces the yield of vitriol from a set of chambers as to render the process one that is somewhat expensive. Apart from this, however, it is not at every works where hydrogen sulphide is produced that vitriol chambers are available, and doubtless these considerations led Mr. Claus to devise his ingenious kiln for the recovery of sulphur in the free state from this gas (Eng. Pat. 3603, July 29, 1882).

No one who has seen the splendid results obtained with the Claus kiln, especially by the United Alkali Co. at Widnes, can have any doubt about its success. It is, therefore, not without some hesitation that the author brings before you a method which, although it cannot supersede the Claus kiln, may yet, under special conditions, be considered to have certain advantages over the older plan.

My process is to burn the hydrogen sulphide in an atmosphere highly impregnated with sulphur dioxide, whereby 50 per cent. more sulphur can be obtained with the same amount of hydrogen sulphide than is possible by the Claus method, according to the following equation :—

The practical result of the operations in the Claus kiln, leaving out intermediate reactions and only keeping in view what goes in and what comes out of it, may be represented by this equation :— $2\text{H}_2\text{S} + 2\text{O} = 2\text{H}_2\text{O} + 2\text{S}$ , clearly showing how the new process gives so much more sulphur with the same quantity of hydrogen sulphide.

The reaction can be made to take place in an ordinary pyrites kiln, into which the hydrogen sulphide is properly admitted, with due regulation of the supply of air to the kiln. Or a combustion chamber may be provided, the two gases being led into it by separate passages.

The sulphur, which sublimes, can be collected in brick chambers in the same manner as is done in the Claus process. These, however, will require less provision for the drainage of water in proportion to the amount of sulphur made.

II.—The above portion of this paper was written in the autumn of 1893, after the author had obtained provisional protection for improvements in the manufacture of sulphur (Brit. Pat. 15,421 of Aug. 14, 1893).

It may be interesting to explain how the idea of the process was arrived at.

At the works with which the author is connected, the  $\text{H}_2\text{S}$  from the sulphate of ammonia saturators used to be burnt in a pyrites kiln of the old pattern, having a long hearth. The conversion of the  $\text{H}_2\text{S}$  into  $\text{SO}_2$ , which went forward into the vitriol chambers with the gas from the pyrites, was effected without any cause for complaint. It was decided to replace the old kiln by new pyrites burners on the modern pattern. The nozzle for burning the  $\text{H}_2\text{S}$  was introduced through the front wall of the new burners, some half way between the top of the pyrites bed and the roof of the kiln. The presence of sulphur at every available opening proved that some detail had been misunderstood. The admission of air to any reasonable extent seemed insufficient to abate the trouble, which, however, was eventually overcome, although it took some considerable time to exactly find the actual requirements in this respect.

It was natural that one should try to understand the cause of the extraordinarily copious production of sulphur referred to. The author became convinced that, in the

absence of sufficient air, the reaction that has been explained between the  $\text{H}_2\text{S}$  and the  $\text{SO}_2$  was the true cause. Seeing, further, the excellent character of the sulphur produced by this accidental process, it seemed quite possible to advance a step on the Claus process, as has been already mentioned. The specimens of sulphur before you were deposited in the tunnel leading the gases from the pyrites burners into the chambers. They will convince you of what could be done by the use of proper appliances when such an excellent material was the result of mere accident.

It will naturally be asked, Why was so promising a process not gone on with? To rely on the reaction as a protection for the patent was of course out of the question. The reaction coupled with particular sources of the two gases seemed more promising; still, it appeared to be better to depend on some special design of the plant.

The writer therefore waited for the time when he might be in a position to make the experiments necessary to take out such a patent.

Probably this matter would not have yet come before you had it not been that Messrs. Brock and Hurter have obtained protection for what is practically the invention that has been described to you (Brit. Pat. 13,844, June 23, 1896), an abstract of which appears in the Journal of our Society, Vol. XVI., p. 536. The object of this paper is in no way to institute any prior claim, but rather to show the great value that may attach to the invention, and to bear witness to the excellence of the product and likely efficiency of the process.

One must suppose that Messrs. Brock and Hurter's claim is founded on the plant and apparatus, although a superficial glance at the abstract in our Journal might lead one to infer that they relied for its protection on the reaction between the two gases concerned.

This forms a telling illustration of what can happen with our present patent laws. Formerly, assuming that the invention of Messrs. Brock and Hurter had been the same as that of the author, it could not have stood, as the latter would have been published, even though only provisional protection was accorded to it. At the present time, however, inventions that are only provisionally protected remain secret, and the consequence is the possibility of an inventor who has patented a process, but who has allowed his privilege to lapse after provisional protection, finding that he cannot use his own process without the permission of a subsequent patentee. When the provisional specifications were published after the abandonment of a patent this could not happen, but of course the whole world was also at liberty to use the invention.

There is, however, another and very different point of view. A patentee who finds that he has made a serious blunder in a provisional specification, can now drop it and take out another patent without disclosing anything to the public or to his rivals that might lead to his being anticipated. Nor could anything that he may himself have said in his abandoned specification do him any injury when taking out a new patent. This might well happen, and in fact, to the author's knowledge, did happen on one occasion when the specifications of patents that had only been granted provisional protection were published.

#### DISCUSSION.

Mr. R. M. CAVEN said that the reaction between  $\text{H}_2\text{S}$  and  $\text{SO}_2$ , by which sulphur was liberated, was well known as a lecture experiment. He supposed, however, that the object of the paper was to show its application to a practical purpose. He did not see that the proposed process made made any more sulphur from the  $\text{H}_2\text{S}$  than the Claus process did. The extra amount was obtained by using something that added to the total of the sulphur-containing gases.

Mr. L. ARCHBUTT asked what part the oxide of iron took in the experiment described. Was the Claus kiln mentioned in the abstract of Brock and Hurter's patent an essential?

Mr. ADAMS said it seemed unnecessary to use any pyrites. The  $\text{SO}_2$  might be obtained by burning a portion of the  $\text{H}_2\text{S}$  in air and mixing it with the other portion of the  $\text{H}_2\text{S}$ .

The CHAIRMAN remarked that, although only remotely related to the subject, he might mention that they had been recently accused of emitting  $\text{H}_2\text{S}$  from the top of some blast furnaces. Although  $\text{H}_2\text{S}$  would no doubt be generated within the furnace, he failed to see how it could remain as such in the flame at the top.

Mr. CAVEN, replying, said it was quite true that material containing sulphur had to be supplied in order to get, in process described, the extra yield over the Claus process. As, however, such material could be obtained very cheaply, the objection had little force. At the Sharon Chemical Works, for example, they had hundreds of tons of pyrites smalls from coal brasses, which, although containing some 30 per cent. of sulphur, were merely grinding the ground for want of some such process. He would add that the difficulty of carrying on experiments with these gases was very great, owing to the stringency of the Alkali Act. He felt quite confident that plant could readily be put up to render the recovery of the sulphur contained in the smalls referred to commercially successful, but there was always the danger that it might not be possible to do it without a greater escape than the Act allowed, *viz.*, 4 grains. Indeed, he might say that this was only a legal limit, for, as a matter of fact, the average escape from their vitriol chambers would not be more than half that figure. So low was it at times that the last test taken by Her Majesty's Inspector was only 0.3. To hope to approach such figures with experimental plant was out of the question, and the fear of normally exceeding the Act limit, after spending a considerable sum, and being unable to come within it without such further expense as to render the process a losing one, was decidedly a deterrent. In reply to Mr. Archbutt, he did not think that the oxide of iron took any part in the reaction between the  $\text{H}_2\text{S}$  and the  $\text{SO}_2$  in the pyrites kiln. The burning pyrites emitted  $\text{SO}_2$ , which met the  $\text{H}_2\text{S}$  being fed into the kiln some distance above the bed of pyrites. Certainly in the abstract of the patent to which reference had been made (this Journal, Vol. XVI., p. 536), it was stated that Brock and Hurter passed the mixture into a Claus kiln, so that possibly in that case the oxide of iron did take some part in the reaction. The process mentioned by Mr. Adams had been before suggested for obtaining sulphur from  $\text{H}_2\text{S}$ , but in that case the assistance that the process described in the paper gave to get sulphur from an otherwise worthless pyrites was sacrificed.

#### THE ESTIMATION OF CUPROUS OXIDE BY MEANS OF STANDARD POTASSIUM PERMANGANATE SOLUTION.

BY R. M. CAVEN, B.Sc., F.I.C., AND ALFRED HILL,

*University College, Nottingham.*

ONE of the authors was recently engaged in the investigation of the composition of a mixture of cuprous oxide with metallic copper and an insoluble basic cupric salt, and it was found desirable to estimate the proportion in which the cuprous compound occurred, by means of a volumetric method depending upon its oxidation to the cupric state. The use of chlorine, bromine, or iodine in any form for this purpose is inadmissible, because, when a solution of a cupric salt is brought into contact with potassium iodide and starch, such as would be used as an indicator in connection with the above oxidising agents, a blue colour is at once produced, owing to the liberation of free iodine, consequent upon the formation of cuprous iodide.

Some preliminary qualitative experiments showed that an acidified solution of potassium permanganate readily oxidises a cuprous compound to the cupric state; and we have succeeded in making use of this reaction for the estimation of cuprous compounds, and more especially of cuprous oxide.

A solution of cuprous chloride in hydrochloric acid is completely oxidised by a solution of potassium permanganate, but considerable difficulties have to be overcome in the adaptation of this process for quantitative analysis. The reason for these difficulties is twofold.

Firstly, the solution of cuprous chloride very readily undergoes oxidation on exposure to air, and the results would therefore be low from this cause.

Secondly, the use of hydrochloric acid in connection with potassium permanganate solution is liable to be attended with oxidation of the acid itself and the evolution of chlorine. This result would introduce a positive error into the determination; and indeed, unless the oxidation of the hydrochloric acid is prevented, the end of the reaction is rendered very uncertain by the gradual fading of the permanganate solution, after a supposed fixed point has been reached.

The first of these difficulties has been overcome by excluding air from contact with the solution during the titration, by means of a current of carbon dioxide gas. The second difficulty was met by employing a solution of magnesium sulphate in conjunction with the hydrochloric acid, and always carrying out the titration under similar conditions.

The most favourable conditions for success were ascertained by a series of preliminary experiments, with different proportions of acid, magnesium sulphate solution, and water. Air-free water was used throughout the experiments, both for dilution and for the preparation of the solutions of hydrochloric acid and magnesium sulphate.

The following is the manner in which we have carried out the volumetric estimation of cuprous oxide according to the above principle.

The cuprous oxide, from whatever source obtained, having been thoroughly washed with hot water, to remove any soluble impurities adherent to it, is received in a stoppered tube of 100 c.c. capacity, and a little water is added to it. The air is then expelled from the tube by means of a brisk current of carbon dioxide gas, and during the passage of the gas, dilute hydrochloric acid (1 part strong acid to 3 parts water) is added from a pipette in sufficient quantity just to dissolve the cuprous oxide. The mouth of the tube is closed and the contents gently agitated to effect complete solution. The liquid thus obtained should be quite colourless.

Meanwhile about 300 c.c. of cold, air-free water are placed in a beaker of 450 c.c. capacity, together with a quantity of magnesium sulphate solution, containing 300 grms. of the crystallised salt per litre. The volume of this solution used must not be less than double that of the dilute hydrochloric acid employed to dissolve the cuprous oxide.

In most of our experiments from 20 to 25 c.c. of dilute acid and 50 c.c. of the magnesium sulphate solution were used.

A stream of carbon dioxide gas is directed on to the surface of the liquid in the beaker, the solution of cuprous chloride quickly added from the tube, and the titration immediately proceeded with. A white precipitate of cuprous chloride will be formed on pouring the solution into the water in the beaker, unless an undue excess of acid has been employed. The formation of this precipitate is advantageous, since in this case atmospheric oxidation is much less likely than when the cuprous chloride remains in solution.

The solution of potassium permanganate used should contain about 5 grms. of the salt per litre.

If the experiment is carried out under the above conditions, no difficulty is experienced in judging the end of the reaction, since a pure pink colour remains for a long time without fading. This colour is slightly bluer than that due to potassium permanganate alone, owing to the cupric salt present. If the proportion of magnesium sulphate to hydrochloric acid is diminished, the pink tint of the permanganate fades after the oxidation of the cuprous oxide is complete, owing to the action of the oxidising agent upon the hydrochloric acid, and if the proportion of water is diminished a similar effect is observed. We have also found that by using a larger proportion of water than that stated above, irregularities are introduced which interfere with the accuracy of the process.

The following results were obtained in the estimation of the cuprous oxide precipitated from Fehling's solution by a known volume of a solution of invert sugar.

The amount of cuprous oxide which was obtained from an equal volume of the invert sugar solution, and which was weighed as such on a tared filter, is placed side by

side with the amounts calculated from the results of the titration:—

	Cu <sub>2</sub> O titrated,	Cu <sub>2</sub> O weighed.
	C.c. KMnO <sub>4</sub> Solution	Gm.
I.	17.2	0.1937
II.	17.3	0.1948
III.	17.4	0.1959
		0.1970

The weight of Cu<sub>2</sub>O corresponding to the potassium permanganate solution used is calculated by multiplying the oxygen value of the number of c.c. employed by the factor  $8.91 \left( = \frac{\text{Cu}_2\text{O}}{\text{O}} \right)$ .

The above results are a little low, owing to the fact that, however great the precautions taken, slight oxidation of the cuprous solution does take place previous to its titration. It will appear that much care is necessary for the carrying out of the above process, and that it may easily fail if any of the precautions above mentioned are neglected. With practice, however, fairly accurate results may be obtained, and the process is quickly carried out.

We have now to describe a modification of the above process, in which the use of hydrochloric acid, and also of carbon dioxide gas, is done away with, and which can therefore be performed with greater ease and expediency. Cuprous oxide cannot be dissolved by oxy acids, such as sulphuric and phosphoric acid, because the corresponding cuprous salts do not appear capable of existence under ordinary conditions. In such cases the cuprous oxide is resolved into metallic copper, and the cupric salt of the acid used. Sulphuric acid, therefore, cannot be substituted for hydrochloric acid in the above process. Various other solvents for cuprous oxide were tried by us in order to dispense with the use of hydrochloric acid, and so of magnesium sulphate, but without success. Potassium permanganate solution acts slowly upon the metallic copper, separated from cuprous oxide by means of sulphuric acid, but such oxidation cannot be employed as the basis of a volumetric process.

Dr. Frank Clowes suggested to us that possibly by mixing together sulphuric acid and potassium permanganate solution in suitable proportions, and adding this mixture to the cuprous oxide, the separation of metallic copper might be prevented. This we have found to be the case. Cuprous oxide dissolves completely in a solution of potassium permanganate acidified with sulphuric acid, forming cupric sulphate.

We have therefore employed this reaction as the basis of a modified process, by means of which cuprous oxide can be estimated volumetrically. Excess of the acidified potassium permanganate solution is added to the cuprous oxide, and the resulting solution is titrated, under suitable conditions, with a solution of oxalic acid until the purple colour of the permanganate is discharged. The following are the experimental details of the process:—

Dilute sulphuric acid (1 part of acid to 3 parts of water) is added to the standard potassium permanganate solution in the proportion of four to one. 25 c.c. of the permanganate solution suffice if the quantity of cuprous oxide does not exceed 0.2 gm., and a mixture of this with 100 c.c. of the dilute acid is poured upon the clean cuprous oxide contained in a beaker of suitable size. The liquid is stirred with a glass rod to promote solution, and when the cuprous oxide is dissolved, boiling water is added to the solution in sufficient quantity to raise the whole to a temperature of 45°—50° C., care being taken not to exceed the latter temperature. Standard oxalic acid is then added until the colour of the permanganate solution is discharged. A neutral tint is produced just before the end of the reaction, this being due to the mixture of the pink colour with the bluish tint of the cupric salt. Finally, after becoming nearly colourless, the solution assumes a clear bluish-green colour, and the indication of the completion of the reaction thus observed is very delicate.

It is convenient to employ oxalic acid solution of such a strength that 1 c.c. is equivalent to 1 c.c. of the potassium permanganate solution. The volume of the latter solution

employed for the oxidation of the cuprous oxide is then obtained by subtracting the number of cubic centimetres of oxalic solution used from 25 c.c. The oxalic acid solution should be standardised by the use of the acidified permanganate solution in the same manner as in the actual estimation.

The vessel containing the acidified permanganate solution must not be heated by means of a flame previous to use, as local overheating tends to cause the separation of a brown precipitate of a hydrated oxide of manganese on the subsequent addition of oxalic acid; and in any case the results are variable if the temperature of the solution is too high.

We obtained the two following pairs of results by titration and weighing of the amounts of cuprous oxide, which were precipitated from Fehling's solution in each case, by equal volumes of solutions of invert sugar:—

	Cu <sub>2</sub> O by Titration.	Cu <sub>2</sub> O by Weighing.
I.	0.1943	0.1960
II.	0.1953	0.1947

The most important application of this process is its use in the analysis of sugars by the determination of their cupric reducing power. For this purpose the hot solution of sugar is introduced into excess of Fehling's solution contained in a beaker immersed in the water bath, and the reduction allowed to proceed for 14 minutes, according to the method recommended by C. O'Sullivan (Watts' Dict., art. Sugar).

After the removal of the beaker from the water bath, the clear blue supernatant liquid is decanted through a suitable filter, and the precipitate washed several times by decantation until it is free from alkali and organic matter. Care should be taken to transfer as little as possible of the cuprous oxide to the filter during the process of washing.

When the cuprous oxide, both in the beaker and on the filter, is quite clean, a small quantity of the previously prepared acidified permanganate solution is poured upon the filter so as to cover the red stain of cuprous oxide, and it is allowed to remain in contact with the filter for a few seconds only. A pointed glass rod is next pushed through the bottom of the filter paper, and the paper is then thoroughly washed with hot water, the solution and washings being allowed to run into the beaker containing the cuprous oxide to which the remainder of the acidified permanganate solution has been previously added. The action of the permanganate upon the filter paper itself during the time during which the solution is in contact with it is so slight as to be negligible. We could not detect any diminution in the oxidising power of the permanganate owing to such contact. A slight stain of metallic copper is sometimes left upon the filter paper, but this too, when it occurs, is so small as not to affect the accuracy of the titration. Any possible error which might arise from incomplete oxidation of the cuprous oxide on the filter, is best avoided by allowing the precipitate to settle thoroughly after each washing, so as to transfer very little precipitate to the filter. We find that the whole process can generally be completed within about half an hour of the removal of the beaker from the water bath.

The following results, expressed in percentages, have been obtained by us in the analysis of two samples of sugar by this process. The factor 0.5045 has been used for the conversion of weight of cuprous oxide into weight of dextrose, levulose, or invert sugar. Analyses carried out by direct weighing of cuprous oxide are placed side by side with the results obtained by the volumetric method:—

#### Analysis of "Brown Sugar."

	Volumetric Method.	Gravimetric Method.
Glucose .....	11.7	12.1
Sucrose .....	82.0	82.4
Moisture .....	4.7	4.7
Ash .....	0.8	0.8
	99.2	100.0

#### Analysis of "Preserving Sugar."

	Volumetric Method.	Gravimetric Method.
Glucose .....	1.2	1.1
Sucrose .....	92.6	92.2
Moisture .....	5.7	5.7
Ash .....	0.4	0.4
	100.0	100.4

The authors are of opinion that this process will be found distinctly quicker than methods depending on the weighing of cuprous or cupric oxide, even leaving out of consideration the time necessary for the drying of the precipitate when it is weighed in any form. The permanganate solution when once standardised will keep unchanged for a long time, and the solution of oxalic acid will remain at a constant strength for several weeks.

It will be evident that the process can only be applied for the estimation of saccharine substances which will precipitate cuprous oxide in such a state that it can be readily washed free from organic matter. Whenever, in fact, it is permissible to weigh cuprous oxide as such, this method may be substituted for the gravimetric process with considerable saving of time.

#### DISCUSSION.

Mr. ARCHBUTT said he thought it would be a great advantage to be able to estimate the cuprous oxide by titration rather than to weigh it. In order to do away with any possible action of the filter-paper, why not filter through asbestos? It might also be found advantageous to use hydrogen peroxide instead of oxalic acid to estimate the excess of permanganate. It had the advantage that it could be used in the cold, and he might say could be prepared at any time by dissolving sodium peroxide in dilute sulphuric acid.

Mr. ADAMS described a method of preparing asbestos filters. Long-fibre asbestos was cut up into bits about an eighth of an inch long, washed with hydrochloric acid, suspended in water, and a small quantity poured into a Gooch crucible held air-tight in a funnel by means of a piece of india-rubber tubing, and connected up to a filter-pump. The thin mat of fibres thus formed made an excellent filter.

#### SESSION 1897-98.

Tuesday, Jan. 25th:—

Mr. L. Pitblado. "Cyanide Practice in the Marikuppam Field."  
Mr. Charles J. Ellis. "Testing of Gold Ores, &c. in relation to their Treatment by the Cyanide Process."

Meeting held at Broxburn on Monday, Nov. 29th, 1897.

MR. G. T. BEILBY IN THE CHAIR.

### THE AUTOMATIC MECHANICAL DRAWING OF SHALE RETORTS.

The CHAIRMAN said that as the first item on the agenda was the reading of certain papers and discussion on the mechanical drawing of shale retorts, he thought it desirable to pass in review on the screen the historical collection of retorts which were shown at the October meeting in Glasgow.

The retorts were then shown on the screen.

## THE HISTORY OF SHALE RETORTS AT BROXBURN.

BY NORMAN M. HENDERSON.

It is perhaps quite appropriate that the Scottish Section of the Society of Chemical Industry should meet at Broxburn to discuss the retorting of shale, for Broxburn district has been associated with the manufacture of oil from shale for over 36 years, and it may not be out of place for me to give a summary of the history of the trade.

It was in 1859 that Mr. Robert Bell leased the minerals in this district, for the purpose of working coal and iron-stone. He shortly afterwards found large supplies of rich shale on the ground, capable of yielding over 30 gallons of crude oil per ton, and he made arrangements in 1861 with Mr. Fauld's, of Glasgow, to supply him with a daily quantity of shale. Mr. Fauld's, in company with some others, erected a small work in 1862, just north of the canal, and set up 36 horizontal retorts, but they abandoned the works shortly afterwards, because the price of crude oil fell below 1s. per gallon. Mr. Fernie then took them up, in 1864, added 32 vertical retorts, and abandoned them in 1866; but they were again re-started shortly after by a firm known as the "Glasgow Oil Company."

In 1862, Mr. McIntock also erected 12 horizontal retorts at Roman camp; these became the property of Mr. Wm. Fraser, of Broxburn, in 1865, who increased the number of retorts to 75, and also erected a small refinery. In 1862 Mr. John Poynter and Messrs. Miller and Steele erected small works at Broxburn; while in 1863 Mr. Robert Bell erected 100 horizontal retorts at Stewartfield, and in 1865 100 horizontal retorts at Greendykes. Then, in 1869, Mr. James Liddell erected a crude oil work of 40 horizontal oval retorts, and these was the last to stop in 1877.

A small refinery was put up in 1863-64, and worked for several years by Mr. Thomas Hureshon.

Most of these little works, however, being unable to continue at a profit, had fallen into the hands of Mr. Bell, when, in 1877, the Broxburn Oil Company, Ltd., was formed, took over Mr. Bell's lease, and started operations on a large scale.

I do not think it is too much to say that the advent of the Broxburn Oil Company, Ltd., opened up a new and brighter epoch in the history of the oil industry in this district. Before they commenced operations, the prices obtained for products were such as would now be regarded as enormous, but the cost of manufacture was so great with the old plant that, despite these high prices, the trade was quite unprofitable.

The old retort plant on the ground, which the Broxburn Oil Company took over, was of various kinds, but mostly horizontals, with a few old verticals. The "horizontals" at Greendykes were mostly cylindrical in shape, and about 9 ft. long; the "horizontals" at the Albyn Works were of various forms—one kind was rectangular in shape, about 10 ft. long, with charging hoppers on the top, and the other kinds were of the oval description, from 2 ft. 3 in. to 2 ft. 6 in. wide by about 1 ft. 3 in. high, and varied from 9 ft. to 10 ft. long. Some of these had charging hoppers on the top, and others were charged from the end, like a gas retort. The buildings and general construction of these retorts were of the most fantastic description, and, if they could be seen now as I saw them, would form an interesting study to the modern oilworks manager.

After four months' trial of these old retorts, while the erection of their refinery was proceeding at Broxburn, the Broxburn Oil Company found that it would never pay to continue using them, and the question of retorts, therefore, became one of paramount importance to the company.

At that time there were several retorts, by various inventors, in the market, the more prominent two competing retorts being Messrs. Young, Scott, and Stephen's, 1872, known as the "Gas Lute" retort, and my own 1873 retort, Patent No. 1327, both designed for the utilisation of the spent shale as fuel.

The merits of all the various retorts were taken into careful consideration by the Broxburn Oil Company, and they finally adopted the "Henderson" retort, 1873 patent.

The erection of these "Henderson" retorts at Broxburn in 1878 proved a great and immediate success. The cost of the manufacture of the crude oil was reduced by 50 per cent., as compared with the cost from the old retorts, and it also effected a very great saving in the costs as compared with the retorts generally in use elsewhere at that time. For example, the cost of the crude oil from the old retorts at Broxburn was 1.28d., while the cost of the crude oil from the "Henderson" was only 2.31d. per gallon. These prices do not take credit for the sulphate of ammonia.

It is also to be noted that the "Henderson" retort gave a yield of 16 lb. to 17 lb. of sulphate of ammonia per ton from Broxburn shale, as compared with 5 lb. to 7 lb. from the old retorts. This larger yield of sulphate of ammonia would further considerably lessen the nett cost of the crude oil, if credited, the nett value of the sulphate of ammonia, after deducting the cost of production, &c., being 14l.

The best retort generally in use elsewhere at this time was what was known as the oval "vertical." The cost of the crude oil from the best constructed of this retort averaged 3.27d., or practically one penny more than the cost per gallon from the "Henderson" retort.

Besides this, the "Henderson" retort with the Broxburn shale gave a yield of 33 galls. of crude oil per ton, and as the retort was worked at a low temperature, the crude oil was of excellent quality, easily refined, and contained a high yield of paraffin scale.

The retort was an intermittent one, and utilised the spent shale as fuel for the next charge by dropping it hot into the furnace below. It was heated from without by the combustion of its own permanent gas and that of the spent shale, supplemented as required with about one quarter cwt. of coal to the ton of shale.

It was heated within by the introduction of superheated steam. The charge was left in the retort for 16 hours at least. The longer the shale was left in the retort, acted on by the superheated steam, the greater was the yield of ammonia; but at this time it was not considered profitable enough to leave it in beyond a certain time, and the time that paid best had to be determined by experience. This suggested that a longer distillation under proper conditions would give increased ammonia.

It is not necessary for me to give any further and more minute description of this retort, because that is already given in a paper by Mr. D. R. Stuart, which appeared in this Journal, 1889, 109; and in the Gas. Inst. Trans. 1887, 21.

Meanwhile the Young and Bellby retort came out, giving its large increase of ammonia, associated with a great increase of temperature inside the retort during the second or ammonia part of the distillation.

This retort has also met with much favour in the trade, and was largely adopted by the oil companies. It seems to be well adapted for the poorer shales containing small yields of crude oil and large yields of sulphate of ammonia; but I have always held that this retort required improvement, and it would be interesting to have the opinion of those who have had experience in its practical working.

In 1889, I took out a patent for "Improvements in the Distillation of Shale," Patent No. 6726, as an improvement on the Young and Bellby method described in this Journal, 1894, 1038.

In this new retort I aimed at getting an increased yield of ammonia by adopting a retort of greatly increased length as the cheapest method of getting the shale a longer time in the retort, and exposed to a larger amount of heating surface, enabling the retort to be worked at a lower temperature, and thereby insuring decrease in the wear and tear and leakage, and a longer life to the retort.

At this stage I would call your attention to the drawings, with description of working.

Fig. 1 shows front elevation and part section.

Fig. 2 shows cross section.

The retorts are vertical, 28 ft. long.

In the upper cast-iron portion of the retort A, the oil is first distilled off the shale at a temperature of about 900° F. The spent shale is then passed downwards into the brick portion of the retort B, which is kept at a constant temperature of about 1,300° F.

The shale in passing down through the retort is kept in constant motion by a toothed roller C at the bottom, which delivers it into a hopper D below at the required rate.

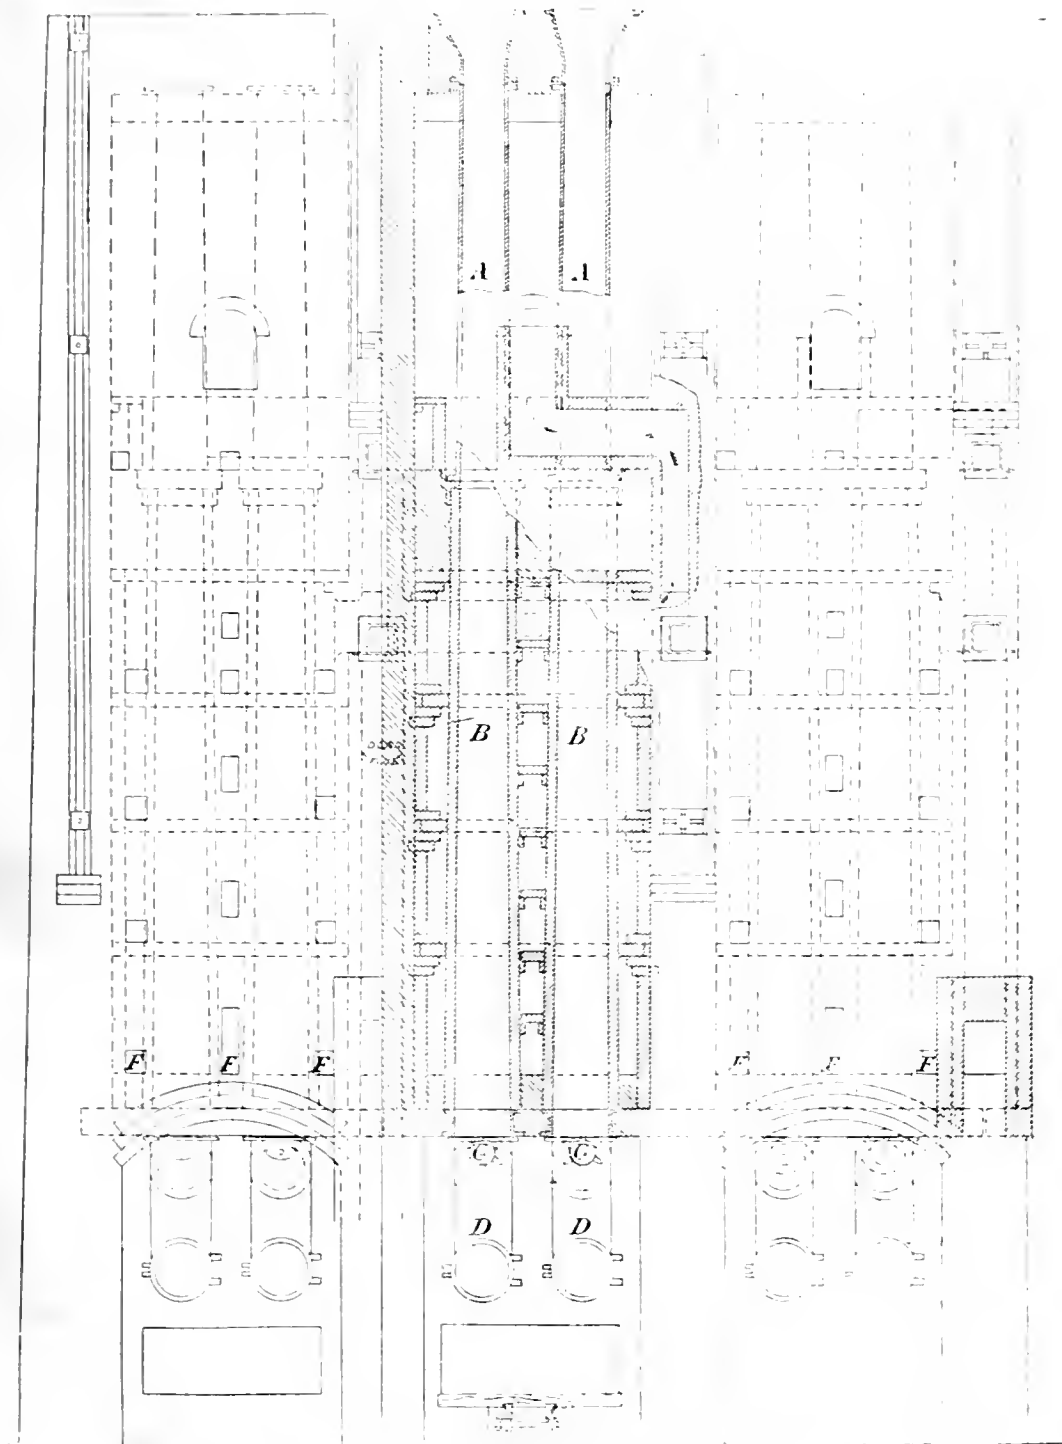

All the products of distillation are drawn off at the top of the retorts through the branch pipe E.

The gas from the producers for heating is introduced at the ports F.

Levers rotate the roller C with ratchet wheels.

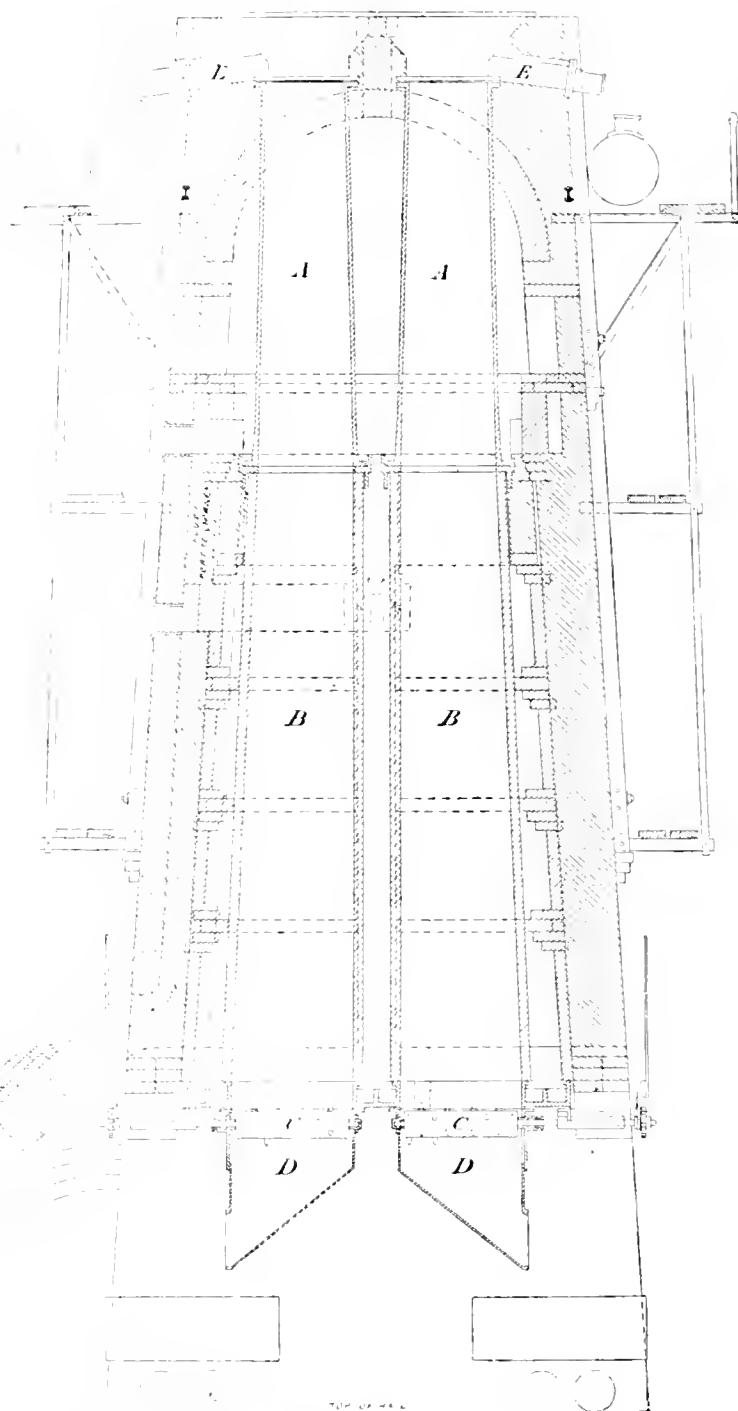

The greatly increased length of the highly heated brick chamber below, allowed for the better graduation of the heat from the bottom towards the top, where it joins the iron retort, and it also secured a better jointing of the iron with the brick retort. The retorts were carefully built with "V" jointed bricks, so as to give them greater strength and

Fig. 1.

BROXBURN RETORTS.—FRONT ELEVATION AND PART SECTION.

Fig. 2.

BROXBURN RETORTS.—CROSS SECTION.

secure absolute tightness; and care was taken at the same time in the construction that free expansion was obtained in the heating chambers.

This lengthening of the retort might have introduced new difficulties, from the danger of local overheating causing fusing and clinkering of the spent shale. To overcome this, I put a toothed roller into the bottom of the retort to cause the whole column of shale to keep constantly moving downwards, and thus prevent any fusion or clinkering. This

continuous downward motion of the shale, by constantly exposing new surfaces of the material to the heat and to the action of the steam, largely increased the yields of oil and ammonia.

In the experimental sets of retorts, I introduced a toothed roller at the bottom of the iron retort to break up the spent shale coming from the oil retort, the shale at this stage being friable and easily broken. I did this in the expectation that the shale, being broken up into smaller fragments,

would be more easily acted on by the steam, and give more readily an increase of ammonia; but it did not have all the effect expected, and caused extra trouble, and the retort was simplified by using only the one roller at the bottom.

Another feature in this retort is that it is heated by gas made from dress coal in ordinary producers apart from the retorts. This was found to be very advantageous in manipulating and regulating the heats, while the flues were kept clean and free from dust, and a saving of fuel effected.

A further feature is the large hopper on the top, which gives a continuous supply of shale and holds sufficient for 18 hours; the advantage of this hopper being that it allows of all the charging to be done during the daytime, and the drawing and tipping to be stopped during the day on Sunday, which is better for both workmen and employers.

BROXBURN HOPPERS.—FRONT ELEVATION.

BROXBURN HOPPERS.—CROSS SECTION.

years ago, and that it has been constantly working ever since without the slightest repair. One set of these was examined only three weeks ago to ascertain its condition, and it was found that both the brick and the iron work were as good and tight, to all appearance, as when they were first started.

These retorts have been exclusively adopted by the Broxburn Oil Company, and I may say that, on the whole, the practical results of these retorts have exceeded my expectations.

The distinguishing features of the retort may be summarised as follows:—

1. The increased surface and capacity of the retort obtained from its increased length, and which gives the shale a longer exposure to the distillation temperature.

2. The moderate heat required in working the retort.

3. The lesser heat at the junction of the brick and iron retorts.

4. The tightness and durability of the retort, secured by the use of the specially jointed bricks.

5. The large hopper on the top, doing away with night charging.

Labour with this retort has been very much reduced, and is of a more pleasant and easy nature for the men employed. A bench of 88 retorts, putting through about 160 tons of shale every 24 hours, is charged by two men during the day, and the spent shale is drawn from the hoppers below into hatches by one man each shift; the hatches are then taken away by the other men.

My aim, then, was to obtain an increase of ammonia without the violent heats of the old "vertical," or of the Young and Beilby retorts. The heightening of the retort, with its moderate heat, gave a greater yield of crude oil by 3 galls. per ton of shale, and an increased yield of sulphate of ammonia from 16 or 17 lb. to 45 lb. per ton from the Broxburn shale, over the old "Henderson" patent retort of 1873.

I may here remark that the first bench of these new retorts was erected at our Broxburn works six and a half

6. The outlet branches being placed on the bottom of the hopper.

7. The constant downward movement of the shale in the retort, caused by the toothed roller in the bottom, and the regulation of the speed of the discharge into the hopper below.

8. The heating of the retort by gas made from dress coal in ordinary producers.

Appended to this paper, I have given a statement showing the comparative costs of the different retorts worked at Broxburn.

*Comparative Results from the Actual Working of the Various Retorts worked on the Broxburn Shale at Broxburn, from 1877 till 1897, as described in this paper; the Shale and Sulphate of Ammonia being charged at the same Values in each instance, that is, the values ruling in 1877-78.*

Description of Retorts.	Total Cost of Retorting, per Gallon, including Shale, Labour, Stores, Maintenance, &c.	Nett Cost of Retorting, per Gallon, after crediting the Sulphate of Ammonia at 14/- per Ton, the Nett Value in 1877-78.
	d.	d.
I. The old horizontal retorts in use at Broxburn in 1877.	4 28	3 91
II. The old vertical retort, the best constructed type of vertical retort in use in 1877.	3 27	2 89
III. The "Henderson" retort (Patent No. 1327 of 1873); first year's working at Broxburn, 1879.	2 31	1 62
IV. The "Henderson" new improved retort (Patent No. 6725 of 1890); present year's working at Broxburn, 1897.	1 80	0 16

It may be interesting to show here the increase of the population of this parish coincident with the progress of the

oil industry, which is the staple industry of the district:—In 1861 the population was 1,500; in 1881, 4,812; in 1897, 10,188.

#### DISCUSSION.

The CHAIRMAN put the following questions to Mr. Henderson. First, "How long is the shale exposed to heat in the Henderson retort as compared with other retorts?" Second, "How much permanent gas does this retort give off per ton of shale, as compared with other retorts?"

Mr. N. M. HENDERSON, in reply, said that the cubic content of the retort was 106 cb. ft., and as 33 cb. ft. of the broken Broxburn shale was generally taken to weigh 1 ton, the shale was  $42\frac{1}{2}$  hours in the retort, drawing taking place at the rate of  $1\frac{1}{2}$  cwt. per hour. In the old vertical retort, the cubic content of which was 26 or 27 cb. ft., and on the same calculation of the weight of shale, and drawing at the rate of  $1\frac{1}{2}$  cwt. per hour, which was equal to  $1\frac{1}{2}$  tons per 24 hours, the shale was in the retort  $21\frac{1}{2}$  hours. In reply to the next question about the gas, he said it was very difficult to determine the exact quantity of gas coming off from these retorts. The only way they had of measuring it was by the exhaustor. The measurements taken from one bench, with a new 30 cb. ft. exhaustor going at 42 revolutions per minute with a  $\frac{1}{2}$ -inch water vacuum on the one side and from 4 to 5 ins. of water pressure on the other, gave practically 10,000 cb. ft. of gas per ton of shale, and this gas yielded about 41 per cent. of combustible matter.

#### THE PHILIPSTOWN RETORT.

BY A. H. CRICHTON.

(FIG. 1.) This is a longitudinal section of the Philipstown

Fig. 1.

LONGITUDINAL SECTION.

retort. It is built on the principle of the Young and Beilby retort, but is a combination of the best of all we knew at the time of erection. There is a bit of Mr. Henderson in it, there is the principle of the Young and Beilby retort, and a good deal of our own—let it be right or wrong. The retort bench is 40 ft. high from the ground to the top rail level. The retort is 28 ft. 9 ins. long including top hopper,  $18\frac{1}{2}$  ft. of brickwork, 10 ft. of iron retort, and hopper  $4\frac{1}{2}$  ft. The section shows an ordinary Young and Beilby gas producer or coal retort in the centre, with two shale retorts on each side, there being two coal and eight shale retorts in the setting. The iron portions of the 10 retorts are all within one large chamber; underneath, the brick portion is divided into four chambers. The gas from the coal retort distils

Fig. 2.

CROSS SECTION

PLAN

downwards and passes out of the retort to right and left into the bottom chamber. At the centre of the bottom chamber on each side the coal gas is joined by the permanent shale gas, whence the whole heating gases ascend by a zig-zag course to the large upper chamber. From this chamber the waste gases are drawn off by two external side flues to the chimney. The connection between the upper chamber and the side flues is by means of a 7-inch iron pipe or flue—each flue being provided with a damper—at each corner of the chamber a little above the floor. We thought the external flues, with downcoming shaft at the end of the bench, preferable to forming descending flues in the walls of the building of the retorts themselves for retaining the gases from the top oven down to the ground and thence to the chimney. At the bottom of the retort the shale rests upon and is drawn by means of a mechanical appliance which we have designed and patented for the purpose. The bottom hopper is empty when the shale is at rest in the retort, and the hopper being placed vertically below the retort, we can look right up to the grippers and see the shale resting upon them by simply opening the bottom door and shutting off the steam for the moment. If anything should go wrong in the inside of any retort, such as "dandering" of the shale, we can empty the retort, and, looking up or down the inside, observe the obstruction and have it removed, either from top or bottom as may be convenient. This can be done with any single retort in a set without interfering in any way with the working of the other retorts. We do not know any other shale retort which can be examined and treated in this way.

(Fig. 2.) This is a cross section of the retort taken on two different lines—one through the shale retort and another through the coal retort, the coal retort being purely and simply the form of coal retort applied to the Young and Beilby. The plan is also shown. We are taking steps, however, to do away with these coal retorts, and have in some benches done away with them, within the last few weeks, not because we find them to be bad gas producers, but because of their structural defects. There is a good deal of tear and wear on the coal retorts, and repair is necessitated on them when none is required on the shale retorts. We have had shale retorts at work now for more than four years which have never been entered, while the coal retorts on the same benches have had to be repeatedly repaired, especially at the furnaces, thereby interfering very much with the working of the shale retorts. We have erected some gas-producing plant alongside the benches, introducing the coal gas from the outside.

Fig. 3 is a drawing of the mechanical appliance, showing horizontal section through two retorts—one at bottom of brick part of retort, and the other immediately above the apparatus; also elevation showing external parts and vertical section. The apparatus is exceedingly simple. Through the bottom iron hopper we have two transverse shafts, passing through bottom hopper from the back to the outside of outer wall of bench. These shafts work into a plain boss at the back of the hopper and pass through an easy-working stuffing-box at the front to the outside of the bench. The outer ends of the shafts are carried on an iron bearer with coil and cover; on the end of each shaft there is an arm connected by links to a hand-lever, the two arms crossing each other as shown. Each shaft is fitted with a set of cast-iron arms or grippers. When closed and supporting the shale at rest in the retort, these arms are at an angle of  $45^\circ$ , and when full open are vertical. The grippers are opened and the shale relieved by an upward movement of the hand-lever, and closed by pulling the lever downwards. When drawing the retorts, a hatch is placed under two retorts, back or front, and half a hatchful taken from each retort. The system followed at present is to draw the retorts once in six hours, the throughput of shale being about the same as with the Young and Beilby and the present Henderson retorts. There is perfect control over the movement of the shale within a retort. You can take out a bonnetful or a hatchful, just as you please. There is no difficulty in that respect. The bottom door-piece and door have turned edges; the door is hinged, and kept tight when closed by means of a concentric link, which is hampered on to the bow of the bottom door of the retort.

Fig. 3.

MECHANICAL APPLIANCE FOR REMOVING SOFT SHALE.

ELEVATION.

VERTICAL SECTION.

HORIZONTAL SECTION.

There is no screw there, although a screw is shown on the plan. We found, like many others, that the screws got very soon unworkable in the moist atmosphere which pervades the bottom of the retorts, and we have now simply the concentric link, which was designed by our late foreman, Mr. Muir, and forms a neat useful contrivance.

## PUMPHERSTON PATENT RETORT.

BY JAMES BRAYSON.

The description of this retort naturally follows that of the Broxburn and Philipstown designs, being of a later date than either; and, as will be seen, it differs essentially from any of the forms which have been referred to in the previous papers.

Prior to the introduction of the new retort, the Pumpherson Company had distilled about 3,000,000 tons of shale by the Young and Beilby retort.

While always sensible of the advantages gained by the use of the Young and Beilby retort over the older forms of retorts, our experience convinced us that the subject had not been exhausted, and that finality had not yet been reached. Like many others in the Scottish oil trade, many modifications on the Young and Beilby retorts had been tried by the Pumpherson Company, with no practical advantages in any case. At the Seafield works of the Company two benches of 80 retorts each were built with an increased height of five feet, part of the increase being on the brick and part on the iron portion of the retort. This modification proved to us that any step in the direction we had taken only led to an aggravation of the difficulties connected with the working of the original Young and Beilby retort, *viz.*, sticking and daudering, with all the consequent evils connected therewith, and that such modifications did not lend themselves to greater economy in working.

It was after the foregoing experience that we determined to make some efforts towards the solving of the problem of retorting shale. In facing this question we had before us the fallacy in principle which, as it appeared to us, existed in all previous forms of retorts, *viz.*, that it was essential to the proper heating of the shale in the centre of the retort that the retort itself should be of very limited dimensions in its breadth, so that the external heat on the retort should be brought as near the centre of the shale within the retort as possible.

We were of opinion that such limitation of the size of the retort was fallacious, and on certain lines of construction might be ignored.

In view of the foregoing we were of opinion that a retort might with great advantages be constructed on the following lines:—

1st. Of large dimensions and capable of a greatly increased throughput compared to anything hitherto known to the trade.

2nd. That the whole structure must be designed and constructed upon lines of a much more substantial nature, and freed from all the structural weaknesses which had belonged to retorts hitherto in use at high heats.

3rd. That to effect economy in working, which was a leading condition aimed at, a passage should be constructed underneath the retorts, running parallel therewith from end to end of each bench.

4th. That the discharge from the retort should be continuous, or nearly so, and free from danger of intermittent movement.

The first point practically dealt with was the discharge or bottom part, this having an important bearing on the foundation building, and in the working out of this the shape of the retort itself was developed. As will be seen from the illustration, there is, at a distance from the lower end of the retort, a cast iron table or disc fixed to the inside of a box casting in such a manner that a space is left all round between the edge of the table and the sides of the box. This box is carried to a sufficient depth so as to form a hopper for the discharged shale. When shale is filled into the retort it rests on the table, while the space leaves room for some passing over the edge. Through the centre of the table a steel spindle or shaft projects, on the upper end of which is a curved arm, and this when rotated wipes the shale off, causing it to fall over the edge of the table into the hopper below.

The cast-iron hopper is formed so as to enclose the mechanism mentioned, and is large enough to take in two retorts, so that one outlet serves for the two. This outlet is closed by a conical lid, which is worked by steam pressure acting on a small piston and cylinder, and proves a quick

and reliable means of emptying the hopper of its contents. The shaft carrying the curved arm passes through the bottom of the hopper and has a ratchet and lever fitted to the lower end. This is actuated by a bar or rod of tee iron, which is made to travel horizontally, being driven by gearing from a small steam engine. The bar in travelling moves the ratchet lever, which in turn moves the vertical shaft carrying the curved arm. The motion is comparatively slow, as the arm has only to make one revolution in 90 minutes or thereby. The action is most satisfactory, and the throughput of shale can be regulated at will.

Having such a bottom part, it is apparent that to get the hatch immediately under the opening was most desirable, and this decided the form of the foundation piers, which, as will be seen, are built so as to allow for a passage right under the middle of the bench, and running from end to end thereof. It will be readily understood that when the table and curved arm were found to work so satisfactorily, the desire to have the retort naturally arose, and the advantages and disadvantages of such a form had to be considered. Hitherto the idea had prevailed that it was essential to have the retort made rectangular or narrow in some direction, so that the distance from the centre of the shale to the heating surface might be kept as little as possible. This idea was deliberately set aside, we being convinced that, given a retort large enough to allow a slow and regular passage of the shale, there will be a fairly equal heating throughout, and if that was so, then the circular retort had advantages over the rectangular or square section, more especially in that when filled with shale there was less likelihood of free spaces being formed, as might be the case in the corners of rectangular retorts, and also in the fact of there being no such corners, shale would not have the same chance of hanging up, but would pass more evenly down through the retort. Another very important advantage we considered the circular form had over the rectangular was that a more efficient heating flue surface could be made by having no right-angle turns presenting surface for the impinging of the flame in its passage, but, being circular or nearly so, it had the effect of making the gas cling around the walls of the retort, thereby adding to the efficiency of the heating power.

In deciding the dimensions of the retort there were various points which had to be considered, the chief of which of course was how far it would be safe to go in the direction of increased capacity, and, second to that, the difficulties that would accompany such increase in the matter of strength and stability, and also how far the increased capacity would tend to economy in working. After considering all these points we finally decided that a retort 3 ft. at largest diameter and 30 ft. long would probably best fulfil all the conditions.

With these dimensions we got a retort about 150 ch. ft. capacity, excluding top and bottom hoppers. The top hopper, made of mild steel plate, was of sufficient size to contain such shale as would serve for 24 hours without refilling or leaving the gas outlet uncovered with shale within that time. With such a retort we find that a throughput of 5 tons of shale per day can be efficiently worked, with almost a minimum cost.

The next point is the strength or stability of the structure, and reference to the illustration will show how that has been carried out, the triangular pillars projecting between the retorts forming heavy and strong abutments to the walls, while the whole structure is firmly bound by horizontal and vertical binders.

Another point, which is by no means unimportant, which we secured by the construction as described and illustrated by the drawings, is that every individual retort is supplied with its own fuel gas and is isolated from its neighbours up to the bottom of the iron part. By this means the heats can be more regularly kept and adjusted, according to the condition under which each retort may be working. The erection of the first bench of these retorts clearly demonstrated the possibility of retorting ordinary shales without more fuel than that derived from the permanent gases returned from the condensers, and at the present moment the Pumpherson Oil Company have 208 of these retorts working without any other fuel than those permanent gases.

END SECTIONPART ELEVATION

## PUMPHURSTON RETORTS.

SECTION ON A.B

SECTION ON C.D

SECTION ON E.F

SECTION ON G.H

The economy which has been effected may be readily understood by comparing the results which have been realised in actual practice extending over a considerable time.

The average cost of retorting with Young and Beilby retorts was 22*d.* per ton, and with the new retort 12*d.* On the other hand, on comparing the value of the products from the shale, we get a difference of about 1*s.* per ton. These two added together give a difference of 22*d.* per ton in favour of the new retort, which in these hard times would be considered a very handsome profit indeed.

The experimental retort which was erected in 1894 has worked 1,230 days, including various stoppages for examination, and during that time has distilled 1,312 tons of shale of various qualities, without requiring repair in any way whatever—an experience, so far as we know, unique in the history of the Scotch oil trade, and one which goes far to give us confidence to go forward with further erection.

## DISCUSSION.

The CHAIRMAN said that it would have been very interesting if Mr. Henderson had, for purposes of comparison, expressed the actual working costs of his retort in tons, because, as Mr. Bryson had pointed out, the ton was, after all, the unit which had to be dealt with and handled by the workmen. He said that what struck him most in

Mr. Bryson's retort was its great diameter and capacity. Mr. Bryson was right in saying that they all would have been startled 15 years ago to have been told that anyone could work a retort 3 ft. in diameter by external heating alone, and he hoped that some of those present who were actively engaged in working automatically drawn retorts would have something to say on this point, as to how it is that the shale in a retort of such large diameter could be satisfactorily heated through and distilled. The old fear was that as the diameter was increased the external temperature would have to be raised, so that the shale next the skin of the retort would be in a fusing condition before the shale inside was cooked. That was the fear long ago, and it was certainly not groundless under the old conditions. When he had the pleasure of seeing Mr. Bryson's retorts at work a few weeks ago, he had been struck with the uniform character of the spent shale which came from the retort. The series of drawings of the retorts of the past 30 years, which was prepared for the last meeting of the Section, showed how the height of the working part of the retort had been steadily increased, but it was only when Mr. Bryson's retort was reached that the diameter and cross section were seriously increased. Of course, the continuous movement of the shale must be credited with the better and quicker distribution of heat, but within this general statement there was room for

speculation as well as experiment on the possibilities and limits of the method.

Mr. A. H. CHUTEUX said that he had been very much pleased with what he had seen of the working of Mr. Bryson's retort, and highly appreciated the frank and spontaneous way in which information had been afforded those visiting the works. He was pleased that Mr. Bryson had been willing to come forward and publicly read a paper on this subject, and asked Mr. Bryson to supplement his description by giving the value of the heating agent he employed, as compared with that used in the Young and Beilby retort. He considered the question of labour a very important one, but thought that, from what he had been able to see at the works, there was no difficulty whatever in arriving at Mr. Bryson's method of economising labour; but that it had always seemed to him that, while the cost of labour for retorting shale per ton was an exceedingly heavy one, in the distilling of shales the great incubus was the cost of fuel. The elimination of fuel from the cost sheets would mean increased prosperity to the Scottish oil trade. Mr. Bryson had gone a considerable way in that direction, in obviating the necessity of providing fuel for the distilling part of the process; and this, he presumed, meant a distinct saving of between 5*d.* and 6*d.* per ton, taking the average of the last few years. He therefore thought it would be very interesting and instructive to have a record of the value as a heating agent of the permanent gases returned from the condensers of the new retorts as compared with the old form of retorts.

Mr. J. BRYSON, in reply, said he had some difficulty in answering the question, because of the difficulty which Mr. Henderson had mentioned. He had tried very often to measure the quantity of gas, but had never been able to arrive at anything definite. He usually got more than Mr. Henderson gave, and estimated it at something like 13,000 cb. ft. to the ton. He quoted the results of an analysis given by Mr. Rowan (this Journal, 1891, 413) of the gases from the Young and Beilby retorts, then taking that as a comparison and allowing the quantity to be something like 13,000 cb. ft., which he thought most of the users of the Young and Beilby retort would admit to be a fair estimate. A considerable difference is shown in the heating value of the return gas.

Young and Beilby.		Bryson. (Sample taken Feb. 27, 1897.)	
	Per Cent.		Per Cent.
Carbonic acid.....	25.0	Hydrogen.....	55.56
Carbonic oxide.....	4.0	Olefines.....	1.58
Hydrogen.....	13.4	Marsh gas.....	3.70
Olefines.....	1.6	Carbonic oxide.....	9.77
Marsh gas.....	19.7	Carbonic acid.....	22.06
Oxygen.....	1.3	Oxygen.....	1.18
Nitrogen.....	37.0	Nitrogen.....	6.33
	100.0		100.00

The greater quantity of gas from the Young and Beilby, compared with that obtained from the Henderson retort, he (Mr. Rowan) attributed to leakage—a view which was fully confirmed by the high percentage of nitrogen. He stated that a number of samples from his retort had been taken and tested by their own chemists, and the results had been confirmed by other chemists to whom samples had been sent. The large percentage of combustible matter, 70.46, he thought, explained to a great extent the difference in consumption of fuel between other forms of retort and this larger retort. He had no doubt that a great deal was due to the larger capacity with the less surface for radiation, as with a larger quantity of shale in the retort there was a proportionately very much less surface exposed to radiation and loss. These were the only reasons he could give for being able to eliminate the fuel from the heating of the retorts.

Mr. HENDERSON said that the Chairman, in expressing his views on the capacity of these retorts, had talked with surprise of the increase in dimensions. He thought there was much to be learned in that way yet, but he had no doubt that the introduction of mechanical movement in the

retort enabled them to increase the dimensions of the retort, and so to do what had formerly not been possible. He referred specially to the higher percentage of hydrogen in the gases from the Bryson retort, which, as far as he remembered, was about three times as great as in the gases from his own, and thought that the various oilworks managers should have samples of gas taken regularly and analysed, as the results would show whether the retorts were working properly, and would enable them to see that they were not producing gas at the expense of oil.

The CHAIRMAN remarked that the results quoted by Mr. Bryson could not be taken as representing the average composition of the Young and Beilby gas. In his experience the nitrogen content given was abnormally high.

Mr. BRYSON, in reply, stated that he had in some cases got even a higher percentage of nitrogen.

Mr. CHUTEUX suggested that some of the members having a knowledge of the chemistry of the gases produced in the distillation of shale should supplement what had been said on retorting by giving a paper on the heating of retorts. He did not consider the subject a suitable one for a conference of managers, but thought that it should rather be taken up by one man who was specially fitted for the investigation, and who would subsequently give a good practical paper upon which further discussion and inquiry might be founded.

Mr. JOHN D. SOMERVILLE considered that the uniform heating of the shale in Mr. Bryson's retort might be explained on the assumption that the shale at the centre of the retort moved more quickly than that at the sides, which had the resistance of the walls of the retort to overcome, and that as the result of this the shale next the walls of the retort would gradually be moved in towards the centre. He was of the opinion that the shape of the retort, which tapers from above downwards, would favour this turning in of the shale. He further stated that, as this mixing process would account for the uniform nature of the spent shale, it would be interesting to construct a model of the retort, and to study the passage of coloured pieces of shale through it, with a view to testing the correctness of his theory.

#### DISCUSSION ON THE LABORATORY METHODS OF DETERMINING THE YIELD OF SULPHATE OF AMMONIA OBTAINABLE IN THE WORKS FROM A GIVEN SAMPLE OF SHALE.

Mr. J. MORRAY JOHNSTON said that, as he understood the meeting of the Society had been primarily arranged for the benefit of the members of the oil trade, he was of opinion, on account of the probable representative attendance of the chemists connected therewith, that some benefit might be derived from the free interchange of opinion upon the above subject, and he hoped that ultimately a standard method might be agreed upon for general adoption by the trade. He first discussed the method of sampling, referring to the great difficulty of obtaining a fair average sample of shale, and gave his own experience, which had been chiefly derived from the shales of the Oakbank Company. The method which he adopted there, the results of which had been fairly satisfactory on the whole, was as follows. Circular cuttings of all the seams worked by that company were procured, i.e., the actual height of each seam worked, and in these cuttings the total nitrogen was determined by Varrentrap and Will's method of combustion with soda-lime, with the result that he found that from 5.0 to 5.5 per cent. of the actual nitrogen present in the shale was obtained in the form of sulphate of ammonia in the Young and Beilby retorts when in fairly efficient condition. In connection with these figures, he remarked that he had additional proof of their general accuracy from a test, which he had the pleasure of superintending, of two separate 50-ton representative lots of Oakbank shale carried out in Mr. Bryson's experimental retort at Pumphreston: the results of these tests gave somewhere about 58 per cent. of the total nitrogen in the form of sulphate of ammonia, and corroborated the accuracy of the claim made by Mr. Bryson for his new retort, that the yield of ammonia is increased by from 5 to 10 lb. per ton of shale.

Before he gave notice of his intention to bring up this subject at the meeting, he had put himself in communication with Messrs. Steuart and Bailey, the respective chief chemists of the Broxburn and the Pumpherston Oil Companies. As a result, he found that the method used in Broxburn was the old-fashioned tube test, which, although old-fashioned, is an excellent mode of arriving at the yield of crude oil in shale, but which can scarcely be regarded as being very satisfactory for ammonia results. This tube or miniature retort was sealed by means of water, the ammonia water titrated, and the result thus obtained multiplied by two, as being approximately what may be expected in the works from the new Henderson retorts. Mr. Steuart informed him that these retorts give about 70 per cent. of the total nitrogen in the form of sulphate of ammonia, which was certainly very satisfactory; but, in view of the results obtained in Mr. Bryson's retorts, he was inclined to think this figure rather exaggerated. Mr. Bailey, of the Pumpherston Company, informed him that he adopted a method which was supposed to be an imitation of a retort. He heated about 30 grms. of the shale in an iron tube by means of an ordinary combustion furnace, passed steam over the red hot shale for about one hour and a half, absorbed the ammonia gas produced in standard acid, and titrated back the excess of acid. Mr. Bailey maintained that his results agreed precisely with those obtained in the works. He (Mr. Johnston) regretted that he had not yet been able to make any trials with this method adopted by Mr. Bailey. Of the three months described, he was personally inclined to favour that of determining the total nitrogen in the shale, but he was naturally anxious that the most reliable be adopted, and thought a discussion on the subject might be the means of putting them in the way of arriving at this desirable end. He had much pleasure in inviting any members present to favour them with their experiences or any suggestions which they might have to make. Mr. Gray explained that he was in the habit of taking a sample from each natural parting in the shale, and thought it was advisable to take a fairly large sample; in some cases he took from four to eight samples from the seam, according to its thickness, and tested each one separately by itself. He used a small experimental retort holding from 20 to 25 lb. of the shale, and treated it just as it is done in the Young and Beilby retort, distilling off the oil and gradually raising the heat till a good ammonia heat was got while a current of steam was passing all the time. The ammonia water was carefully measured and titrated in the usual manner. He found the results to agree well; the yield of ammonium sulphate was about a pound less than what is got from the Young and Beilby retort in good working order.

Mr. D. R. STEUART said that he had for many years accepted as correct, without any suspicion, a sample taken by making a bore through the depth of the seam, but he subsequently found that bores taken within a few inches of each other sometimes varied in regard to the oil to the extent of several gallons per ton, so that if he wished to know the exact value of the shale, he found it necessary to take the trouble of making a cutting of some size through the seam, or of making an average of several bores. He distilled 2 lb. of the shale in a 2-inch wide tube in the old way, catching all the ammonia in cold water; and if an accurate idea of the amount of ammonia was required, he, at the same time, and alongside in the same furnace, carried out a similar experiment, for comparison, using a shale the exact value of which, as an ammonia producer, had been determined in the works. It was, of course, possible to arrive at an approximation to the amount of ammonium sulphate obtainable, as Mr. Johnston had said, by multiplying the result by two; but he did not claim, in his letter to Mr. Johnston, any special accuracy for the result arrived at in that way; he had, however, found the comparative method satisfactory, and had used it invariably. The total nitrogen in the shale might be used as a basis for calculation, or rather for judgment, but he had not found that the results obtained by the soda-line method always accorded with each other as closely as he could have wished. He had, however, not studied the subject specially.

Mr. E. M. BAILEY said that his experience was, that some shales gave an oil containing a much larger quantity of highly nitrogenous matter than that obtained from other shales, so that the amount of nitrogen present in the oil bore a much larger proportion to that obtained as ammonia in some cases than in others. For this reason he considered, that in the case of two shales so differing, it would be incorrect to assume that the same percentage of the total nitrogen in the shale would be obtained as ammonia in both cases. At one time he used Mr. Steuart's plan, but for the last six years he had used the method communicated by him to Mr. Johnston, and had found it perfectly satisfactory.

Mr. W. CARRICK ANDERSON asked if any of the chemists connected with the various works had compared the results of the Kjeldahl method with those of the soda-line method.

Mr. JOHNSTON, in reply, said that he had not tried the method.

The CHAIRMAN thought that one of the most interesting features in connection with this discussion was that it had shown what a very great need there was for a full ventilation of the whole matter of shale assaying, and that as a Society they ought to do what they could to promote a final settlement of the matter. He would therefore propose that a small sub-committee, consisting of Mr. Johnston, Mr. Steuart, Mr. Bailey, and Mr. Gray, all gentlemen who had spoken on this subject, should take up the matter and report further upon it.

Mr. HARRIS said he had much pleasure in seconding that.

The CHAIRMAN said that their time had now expired, but that it was evidently the desire of the members that this meeting should be adjourned for the further discussion of matters of interest and importance to the oil industry. The Committee would therefore arrange for the holding of the adjourned meeting in February, so as to give sufficient time for the preparation of the various matters to be discussed. In bringing the business of the meeting to a close he proposed that they should convey their hearty thanks, firstly, to Mr. Henderson and the local members and friends who had taken so much trouble to ensure the success of the meeting, and, secondly, to Mr. Henderson, Mr. Crichton, Mr. Bryson, and Mr. Moffat Johnston, who had provided the meeting with such interesting and valuable communications.

Mr. JNO. FIFE gave expression to the interest with which he had listened to the proceedings, and was deeply struck with what Mr. Bryson had said regarding the output from his retort. He thought that Mr. Bryson was wrong in stating the cost of retorting with the Young and Beilby retorts at such a high figure, bringing out a difference of 1s. 10d. per ton, but pointed out that even supposing the result of the improved mechanical arrangement and the saving in fuel and labour to be 1s. 6d. per ton, this gain meant not less than 200,000l. per annum to the Scottish oil trade.

MR. THOS. FAIRLEY IN THE CHAIR.

## NOTE ON THE EXAMINATION OF SEWAGE AND POLLUTED WATERS.

BY WM. MCD. MACKAY AND JAMES MILLER.

THE following results are given for the sake of comparison between the albuminoid-ammonia process and the determination of nitrogen by the Kjeldahl process as applied to the analysis of sewage and polluted waters.

The determinations have been made on samples of River Aire water, four marked "A" being taken from above Leeds, and four marked "B" below Leeds, at a point below where the discharge from the Knotrop Sewage Works enters the river.

The albuminoid ammonia process was carried out as follows:—600 c.c. of distilled water was distilled with a little sodic carbonate till ammonia-free, cooled, and 25 c.c. of sample added; the distillation being then continued as in the case of a drinking water. After the addition of alkaline permanganate all the albuminoid ammonia was found to come over in the first 150 c.c.

The nitrogen by the Kjeldahl process was determined in 500 c.c., boiling down with 10 c.c. strong sulphuric acid (subsequently deducting nitrogen equivalent to the ammonia found as "free"), and proceeding in the usual way for an organic nitrogen determination.

The nitric nitrogen in the first two experiments was nil. In the next two it was not determined owing to inadvertence, but except in the last two it could not materially affect the figures for nitrogen, and in these cases to a small extent only; consequently the nitric nitrogen has been disregarded.

Our object was, if possible, to find a ratio between the nitrogen as determined by the Kjeldahl process, and that by the albuminoid-ammonia process, which could be applied to a number of determinations by the latter process, on samples collected since January 1894. In this we have failed, but we considered the figures found worth recording.

Though the albuminoid-ammonia process has proved such a useful method to chemists in the analysis of drinking water it is not suited to that of sewage or trade effluents, a more absolute means for the determination of nitrogen such as the Kjeldahl method affords is required. At the same time, were this process generally adopted a uniform method of procedure among chemists would be desirable, including some modification eliminating any error due to the interference of nitric nitrogen.

### DISCUSSION.

MR. T. FAIRLEY thought that the difficulty regarding the nitrogen due to nitric acid might be surmounted by using Frankland's method of reduction with sulphurous acid.

DR. J. B. CONYER stated that he had once made a comparison of Wanklyn's, Kjeldahl's, and Dumas' methods operating upon air-dried commercial gelatine and found 10.5, 13.5,

and 15.2 per cent. respectively in the same sample. These results were however obtained using the original Kjeldahl method; the modified one might give better results. If commercial sulphuric acid were used for Kjeldahl's method a blank experiment should always be performed, as the acid always contained small and varying quantities of nitrons or nitric acids.

Prof. H. R. PROCTOR said that in recently collating some results of other chemists, he had found that the average quantity of nitrogen in gelatine, whether determined by the Dumas or the Kjeldahl process, ran about 18 per cent. Gelatine solution gave a larger amount of albuminoid ammonia after slight putrefaction than when quite fresh. The estimation of strong solutions by Nesslerising or by any other colorimetric method was very inexact, because the stronger solution must be diluted to a strength approximately the same as the weaker solution, and any error of observation must thus be multiplied by a large factor. Very considerable differences in the albuminoid ammonia found might be caused by variations in the time of distillation, and the volume distilled; and in factory-effluents matters might easily exist, such as aniline, which yielded "albuminoid ammonia," while containing no putrescible matter whatever.

MR. MACKAY stated that the nitrogen in his sulphuric acid had not been determined. His samples of water had in nearly all cases been taken on the same day of the week, generally Wednesday, so that the results might be more strictly comparable.

After the discussion on Mr. Mackey's paper, Mr. F. W. BRANSON exhibited a model of Marconi's instrument for telegraphing by means of Herizian waves and explained the action of the "Coherer," the most important part of the apparatus, by means of which the waves are detected.

MR. FAIRLEY then showed an apparatus for recovering ether evaporating from open vessels.

A bell jar connected by an elbow tube to a condenser is inverted in a flat crystallising dish over the vessel containing the ethereal solution. Some water is then poured into the outer dish to make the joint tight. The crystallising dish is then set upon the water-bath and the ether distills off.

MR. FAIRLEY also showed a new substitute for a pipe-clay triangle of his own design.

A ring of iron plate is bent as shown in the figure, when

the pieces of pipe-shank which are inserted in the grooves thus formed may be adjusted as required.

Meeting held at the College of Pharmacy on Friday,  
November 19th, 1897.

MR. THOS. J. PARKER IN THE CHAIR.

# ON THE SULPHUR CONTENT OF BITUMENS.

BY S. F. AND H. E. PECKHAM.

WE have read with greatest interest Dr. Endemann's second paper in this Journal upon the analysis of asphalts (this Journal, Feb. 1897, 121), as well as the discussion thereon, and later, upon the paper contributed by ourselves (*ibid.* May 1897, 424).

Dr. Endemann took up the subject of asphaltums only a few months prior to the publication of his first paper. He then, after an investigation in his own way of Trinidad pitch, a Mexican asphalt; and a Texan maltha, propounded certain general conclusions in relation to solid and semi-solid bitumens, with which conclusions we from first to last disagree. These, as we believe, wholly erroneous conclusions do not detract from the value of his work, which, it appears to us, has brought out much respecting the decomposition products of the bitumen extracted from Trinidad pitch and the Texas maltha. This is the scope of his work and nothing more. So far as our experience goes, it is confirmed in every particular by Mr. Clifford Richardson in his discussion on the second paper.

Dr. Endemann tells us that he adopts the name "asphaltene for the reason that it is the main constituent of the asphalt," and "petroleum for the reason of identity." He further says that the "asphaltene of different asphalts has the same composition and identical properties." He also states that asphaltic acid is the cause of the solution of metallic oxides in chloroform. Of more importance is this statement: "Enough, however, had been learned, namely, that what we call petroleum is a complicated mixture. It contains a series of compounds perhaps not even all belonging to a single aliphatic series, but comprising representatives of several such."

In our former communication, we asked several questions, the answers to which appear to us to be fundamental. To put these questions in other words: Does the word asphalt or asphaltum designate an individual substance or a class of substances? Has Dr. Endemann, or anyone else, determined the constituent substances or compounds that together form any variety of natural asphalt or asphaltum? If so, where are the results published? Refined asphalts are manufactured articles, whether solid or semi-fluid. What name does he give the many other solid bitumens, that are wholly unlike the one he selects in composition? Are they asphalts, asphaltums, or what are they?

He states that he treats his natural asphalt so as to get rid of all extraneous substances. He gets rid of his petroleum, which is a complex mixture of undetermined bodies; of all the sulphur, whether free or combined; of all the nitrogen, if there is any, and finally reaches his asphaltene, which he claims is a constituent of all asphalts, but which we claim is nothing but a residue of decomposition, which may or may not be common to all solid bitumens when subjected to his peculiar process. As we understand him, he regards sulphur as a foreign substance, mechanically mixed with solid bitumen. We do not agree with this conclusion. We believe that sulphur has played a very important rôle in the formation of solid bitumens, and are inclined to the opinion that solid bitumens are in many instances largely the result of the action of sulphur upon fluid or semi-fluid bitumens. As we have said previously, sulphur burns out the hydrogen from bitumen, and this reaction may proceed slowly at ordinary temperatures or rapidly at higher temperatures. It is not necessary that the sulphur should be free. It has long been known that sulphates are deoxidised when brought in contact in solution with dead organic matter. If the organic matter has already been distilled into bitumen, the reaction proceeds through double decomposition, a carbonate of the base being formed and hydrogen sulphide, free sulphur, and a sulphur substitution compound remains as a part of the bitumen (*Geol. and Chem. Essays*, T. S. Hunt; pages 87, 99, 145,

163, 230). In proof of this latter statement we have the direct evidence furnished by Mabery's researches upon the sulphur compounds of Lima petroleum. These are paraffin petroleum, and the sulphur compounds isolated are paraffin derivatives. As nothing has been proved concerning the sulphur compounds of solid bitumen, except the few facts stated in our first paper, there is very little upon which to base any general conclusions concerning the sulphur content of bitumens.

In the first place, no writer who has written upon this subject has a word to say concerning the method that he used for determining the sulphur; consequently we have never had any other instructor than experience. While our tutelage has been extended it has also been thorough. It began several years ago while in Southern California, in an attempt to establish, at the request of the Patent Office examiners, specific differences between a solid asphaltic residuum obtained from California petroleum, the same oxidised by prolonged action of air, and after treatment with sulphur. Nearly all of this work was carried on in association with Dr. Frederic Salathé, who said he had examined a large number of natural and artificial bitumens for sulphur. The residuum and sulphurised residuum were tested for sulphur by boiling with fuming nitric acid in a flask with an inverted condenser, and no sulphuric acid was found in the liquids. This method of testing was not then further investigated. Other reactions showed that a compound was formed, which, when oxidised with nitric acid, produced styphnic acid, which is a trioxynitrobenzol—a compound not only interesting, as showing the action of the sulphur, but also as showing that the residuum consisted of benzols. Neither transmitted air nor direct oxidation with nitric acid converted any portion of the residuum into styphnic acid. Treatment of the residuums by deflagration with  $\text{NaCO}_3$  and  $\text{KNO}_3$  showed sulphur in the asphaltic residuum, but only a trace in the same after treatment with sulphur at a temperature of  $409^\circ \text{F}$ . At that temperature the sulphur almost fully burned out with hydrogen, and the bitumen was left dryer and more brittle. This is substantially what Dr. Endemann does to get rid of his sulphur. He has left a decomposition product and nothing else.

Later, we had occasion to determine the sulphur in various bitumens, and recourse was had to boiling with fuming nitric acid, with an inverted condenser. After repeated attempts it was discovered that no quantitative determinations of any value could be made in this way. Addition of potassium nitrate, chlorate, or permanganate was of no avail, and we finally abandoned all attempts in this direction. We believe we have tried every method for the determination of sulphur except the bromine method, and that has never appeared to us to be practicable with solids. Nor has the method of Carius, which we mention here, for fear that by its omission we might be misunderstood. The method which we have finally adopted and now always use, is one that was used for the determination of sulphur in the Pacific Coast coals. (See *Geology of California*, vol. II., The Coast Ranges, App., Cambridge, Mass., 1882, p. 45.) It is susceptible of great accuracy if conducted with care. Two grms. of the bitumen are intimately mixed in a mortar with 16 grms. each of pure, dry  $\text{NaCO}_3$  and  $\text{KNO}_3$  and the whole projected in small portions at a time into a 2-oz. platinum crucible, heated to dull redness, or no hotter than is necessary to cause the mass to deflagrate. Experience will soon teach the manipulator how best to conduct the operation. After deflagration and complete fusion, the mass is dissolved in water, hydrochloric acid added, and the solution either evaporated for removal of silica or immediately filtered, and the sulphuric acid precipitated in the hot acid solution. The barium sulphate is washed, dried, and weighed with the usual precaution. In illustration of the value of this method of determining sulphur when applied to the practical examination of bitumens, we give below the results of an examination of Turrellite—the bituminous coquina found in Uvalde County, Texas.

The mineral itself is a grey mass, apparently of shells, cemented together with bitumen. It is exceedingly tough and difficult to break—a property that is easily accounted for when the material is deprived of its bitumen by being digested in chloroform. The mineral residue is then dis-

covered to be a coquina or shell limestone possessing considerable stability without the bitumen. The shells are cemented together, and the cavities of many of them contain rhomb spar and fragments of other shells, showing that the shell rock had been formed before the bitumen was projected into it.

Analysed by solvents, there were obtained the following results:—

	Per Cent.
Soluble in petroleum ether.....	69.535
Soluble in spirits of turpentine, after.....	39.415
Soluble in chloroform.....	Trace
Soluble in dilute hydrochloric acid.....	81.801
Sulphur in residue.....	0.138
Silica and clay.....	1.432
	100.000

The average total bitumen is 13.536 per cent., of which the petroleum ether soluble is 69.535 per cent., and the spirits of turpentine soluble is 39.415 per cent. This gives a bitumen wholly soluble in spirits of turpentine, of which 69.5 per cent. is soluble in petroleum ether—a very high-grade bitumen. Five grms. of the rock, analysed in duplicate, gave an average of 1.13 per cent. of sulphur in the rock. 1.13 per cent. = 0.1381 per cent. found in the mineral residue, leaves 0.9919 per cent. of the rock, of sulphur in the bitumen, or, of the bitumen 7.328 per cent.

Digestion for several days in water at 60°–70° C., yielded a solution containing 0.126 per cent. of the rock, which consisted of a trace of organic matter and calcium carbonate. There were no sulphates soluble in water. The portion dissolved by dilute hydrochloric acid consisted of calcium carbonate with traces of magnesium, iron, and sulphuric acid. The insoluble residue remaining on the filter consisted of silica, clay, and very small grains of pyrites of appreciable size. Caustic alkalis were without appreciable action on the rock. Fuming nitric acid acted upon it with great energy, dissolving the mineral matter and converting the bitumen into a brittle, charred mass of carbonaceous matter. The bitumen extracted from this rock, when analysed by itself, yielded to—

	Per Cent.
Petroleum ether.....	71.28
Boiling spirits of turpentine, after.....	28.72
	100.00

The results are nearly identical with those obtained from the rock. The sulphur in the bitumen amounted to 7.582 per cent. The bitumen is not acted on by water, strong acids, or alkalis. Fuming nitric acid converts it into a friable, carbonaceous mass.

The above-described work is analytical, as far as it goes. It is admittedly very imperfect, but it tells, nevertheless, its story concerning the constituents of this bituminous rock. There is no reason for believing that there is any oxygen compound in the bitumen contained in this rock. The bitumen is very pure, and while it contains a very large percentage of sulphur, there is no reason for supposing that there are any bases in it made soluble in chloroform by means of asphaltic acid. The bitumen contains only a trace of mineral residue when burned.

We have a large number of determinations of sulphur in solid bitumens. The amount varies from  $\frac{1}{2}$  per cent. to  $7\frac{1}{2}$  per cent. We have never found a solid bitumen free from sulphur. While some bitumens, rich in sulphur, have no perceptible odour, others, like that of the Dead Sea, possess a strong odour of garlic, and without any doubt will be found to contain sulphur compounds that confer upon them very important properties. These compounds are not mechanical impurities, but are constituents, and cannot be overlooked or gotten rid of in any process of analysis that analyses rather than decomposes the natural crude bitumens.

The interpretation of these results in relation to technology is not without value. They indicate a very pure bituminous limestone, free from pyrites and organic matter, containing a heavily sulphurised bitumen. We did not for this reason condemn the material, but we called attention

to the fact that, like other sulphur bitumens, this one was very brittle, and we advised great care in its use, particularly in reference to overloading.

The compound believed to be a thio-salt of iron that was obtained from the chloroform solution of Trinidad pitch, has been analysed, and contains

	Per Cent.
C.....	83.0000
H.....	7.6179
S.....	5.8710
Fe.....	5.5111
	100.0000

This corresponds to  $C_{11}H_{20}FeS_3$  of which the theoretical composition is:—

	Per Cent.
C.....	83.0025
H.....	7.6183
S.....	6.0000
Fe.....	5.3802
	100.0000

One of the determinations gave hydrogen, 7.460 per cent. It will require much further research to determine what carbon group has been deprived of hydrogen to form this compound.

We wish further to call attention, in connection with this research of Dr. Endeemann, to the great difficulties often attending the correct determination of carbon in compounds of carbon and hydrogen that are solid, or even liquid, with very high boiling point. No one will call in question the high authority of C. M. Warren as an investigator of this class of substances. In several conversations held with him many years ago he assured us that he had often found great difficulty in completely burning carbon, even in oxygen gas, when the combustion was assisted by cupric oxide used in any manner. Our own experience confirms Warren's. While we have found that we could duplicate hydrogen determinations to the third place of decimals, the carbon determinations were persistently short in amount, yet not so widely variable as to discredit the accuracy of the determination. We call attention to these facts to show that extreme care should be exercised when determining oxygen by difference.

We again submit that we will gladly welcome any system or method of analysis that furnishes better results than our own.

#### DISCUSSION.

Mr. CLIFFORD RICHARDSON said he was very glad to see how many of his own results were confirmed by what Prof. Peckham had said. He might, however, call attention to the fact that Prof. Peckham's determinations of sulphur were considerably lower than his on the same material, and that, so far as his experience went in the determination of sulphur, the method which Prof. Peckham pursued always gave lower results. It was almost impossible to heat a bitumen with carbonate of soda and nitrate of soda without losing some of the sulphur by volatilisation, whereas the burning of the bitumen in a closed tube in a stream of oxygen could not result in the loss of any which was there in the organic form. Prof. Peckham found 7.5 per cent. in the Uvalde bitumen, as against his 9.8 per cent., and the same ratio in the analysis of the Trinidad preparation which he mentioned. He could also confirm what Prof. Peckham had said in regard to the extreme difficulty of making an ultimate analysis of hydrocarbons such as were found in asphalt. Mr. Byerley, his assistant, has spent months in developing a method which would give satisfactory results. In the first place, carbon and hydrogen had to be determined in the presence of nitrogen and sulphur, which alone made the process decidedly difficult. In the second place, as has been shown by a great many investigators, the attempt to burn these higher hydrocarbons, even in oxygen, frequently resulted, not only in the production of hydrogen and water, but also of acetylene and similar unsaturated compounds. Even with the best and most careful work he and his assistants had been able to devote to such analyses, it was sometimes necessary to make five or six combustions before concordant results could be obtained.

Mr. EDWIN F. HICKS said it seemed to him that, had the sulphur determinations been carried out by heating the bitumens with fuming nitric acid in closed tubes, instead of in an inverted condenser at the ordinary pressure, much more satisfactory results would have been obtained. Digestions of this kind could be easily and effectually accomplished, if, after heating the tube for a short time at a comparatively low temperature, and allowing it to cool, the capillary of the tube were broken, thus relieving the pressure; then, upon resealing, the temperature could be raised to the point necessary for complete decomposition with but little risk of the collapse of the tube, which so frequently discouraged the employment of this method. Had Mr. Richardson, in the course of his determinations of sulphur in bitumens, employed nitric acid under pressure?

Mr. RICHARDSON replied that the only check he made on the determination with combustion with oxygen was by oxidation with nitric acid, and that he had found no difficulty in getting results that agreed within 0.1 per cent. on Trinidad asphalt with nitric acid and a little chlorate of potash at ordinary pressure; but he had no doubt that in most cases, if there was any large amount of work done in that way, it would be done in a sealed tube, that being the most desirable way to accomplish difficult oxidations.

Dr. W. JAY SCHIEFFELIN inquired whether he had tried connecting several combustion tubes together.

Mr. RICHARDSON replied that if they had been merely highly volatile hydrocarbons he should have done that, but that these were not volatile. He thought that that would be a very good idea, and thanked Dr. Schieffelin for the suggestion.

Mr. DEKROODE asked, in regard to this method of determining sulphur used by Mr. Richardson, what became of the nitrogen in these compounds. Was it converted into nitric acid and absorbed by the normal alkali?

Mr. RICHARDSON replied that he did not know. He had seen it in potash and in ordinary combustions. The amount of nitrogen, however, was always very small, and would not seriously affect the determination, but it might to a certain extent.

Mr. DEKROODE said that with nitrogen as high as 0.8 it would seriously affect the sulphur determination.

### THE APPLICATION OF CHEMISTRY TO THE STUDY OF THE MAGNETIC PROPERTIES OF IRON.

BY BERTRAND S. SUMMERS.

IN the present state of science it is difficult to trace other than general relations between chemical composition and physical properties of substances in general. As the chemistry of iron is developed about as well as any branch of the science, we should naturally look for some deduction more or less useful from the study of it. Although there is much that is wanting in this branch of chemistry, it is often possible to trace relations which are exceedingly helpful in commercial practice.

There are reasons to expect a more intimate knowledge of the subject if the proximate analysis of iron can be brought to the point where it can be termed practical and useful. It would seem that a great many of the secrets of iron are locked up in its proximate composition. The microscope has proved an important factor in this connection, but unfortunately, in the present state of the art, it has its limitations. However, it is an important aid when used in connection with chemistry, and often gives a clue to a mystery where chemistry has failed.

Magnetism and magnetic permeability seem to be properties of the iron itself, but are influenced to a very great degree by the metalloids commonly associated with iron. As the latter property is the one that concerns the engineer the most, and as the writer's investigation has been applied chiefly in this field, the paper will deal almost entirely with this branch of the subject. It can in nearly every case be assumed that magnetism and magnetic permeability are opposed to each other, and that a state of the metal favourable to one will be unfavourable to the other.

In examining an iron for magnetic permeability, it is also quite necessary to take into consideration another property of iron, *viz.* hysteresis, that is, the energy lost in magnetising

iron, due to the magnetic inertia of the metal, or the resistance a metal offers to magnetisation. This lost energy is usually rated in watts per pound lost under given conditions.

In general, a metal of high magnetic permeability will usually have a low hysteresis, but there seems to be little or no relation between these two properties. It is not infrequent to find a metal of high magnetic permeability and high loss by hysteresis.

These two properties of iron are what govern its adaptability for dynamo construction and similar purposes. It is with these that the metallurgist is chiefly concerned in the foundry, and as this investigation has been carried on largely with cast metal, most of the deductions are drawn from these varieties of the metal.

In experimenting with cast iron it is exceedingly difficult to draw any trustworthy conclusions, for the reason that the large contents of metalloids make it almost impossible to trace the variations in permeability to any one, or any combinations, of the metalloids. The high percentage of graphite is particularly obstructive in this way, and although it has but little or no chemical effect, its effect on the physical character of the iron makes it difficult to experiment under the same conditions at different times.

After endeavouring to draw some conclusions from numerous tests on cast iron, attention was devoted to making some special alloys. For this purpose wrought-iron borings were mixed with varying proportions of ferro-silicon of the following analysis:—

Silicon.	Graphitic Carbon.	Combined Carbon.	Sulphur.	Phosphorus.	Manganese.
Per Cent. 7.25	Per Cent. 1.95	Per Cent. 0.31	Per Cent. 0.044	Per Cent. 0.597	Per Cent. 0.88

With these two ingredients a series of irons was made. They were placed in a graphite crucible and heated in an ordinary brass-foundry furnace for several hours. When the metal had come to perfect fusion, test bars were cast and tested, and drillings from the same analysed.

These alloys were decidedly peculiar. They did not contain more than a trace of graphite, but the content of combined carbon was usually over 2 per cent. The content of silicon was varied by adding different amounts of the ferro-silicon iron.

A phosphorus iron was made by adding red phosphorus to wrought iron, and when it was desired to raise the phosphorus content, this alloy was added to the mixture of ferro-silicon and wrought iron.

Some of the more characteristic curves are here appended in order to make the comparison more clear. This series was

GENERAL VIEW OF CURVES.

designated as SU series, and the curves are so denominated. The alloys were compounded by endeavouring to keep the other constituents constant while the silicon was varied. This plan was a failure, owing to uncertainties of mixing, and the variation of the carbon due to absorption of carbon from the pot. However, by selecting the curves where the least variation is noticed, we are able to draw some deductions.

In comparing these curves, let us first examine them with reference to the variation of silicon. The curve in Plate I,

PLATE I.

marked  $\pm 50-3$ , is a curve of a very good cast iron, and serves as a means of comparison. It will be noticed that curves SU#1 and SU#3 are more nearly alike than curve SU#2. It might seem at first sight as though this might be due to the silicon content, but a comparison with other curves will show it to be otherwise.

We would naturally expect SU#2 and SU#3 to correspond more closely than SU#1 and SU#3, as the carbon contents are more nearly alike. This difference is due probably to a difference of the state of the carbon and variation in casting condition, which we will discuss later. If we now compare SU#2 with SU#4, we find that their carbon contents are almost identical, while the silicon content in SU#4 is nearly double that in SU#2.

To be sure, the phosphorus varies somewhat, but this does not appear to vary the results, as we will endeavour to show later.

PLATE II.

These curves correspond quite closely, showing that this variation in silicon could not have affected the permeability to any marked degree. Finally, if we compare curves SU#8 and SU#9 we notice that the carbon contents are about the same, but that the variation in silicon is about  $\frac{1}{2}$  of 1 per cent. The other constituents correspond quite closely, at least do not vary greatly. It would seem that if the variation of silicon had any marked effect, the variation is so marked in this case that there should be some effect traceable in the curves. The curves, however, are almost the same throughout their entire range. Also SU#4 and SU#5 are identical while the silicon varies considerably. These with numerous other examples have led to the belief that silicon has little or no direct effect upon the permeability of iron within certain limits. The same seems true in regard to phosphorus.

Comparing curve SU#2 with SU#5, we notice that there is not a great variation in anything but the phosphorus. In this there is a variation of nearly 1 per cent. On comparing the curves, we notice that while there is some variation in the curves, there is hardly what would be expected had phosphorus a marked effect on permeability.

Again, comparing SU#8 and SU#9, we notice that the variation in phosphorus has had no more effect than the variation in silicon.

PLATE III.

The test bars designed to test the effect of sulphur and manganese were unfortunately so hard that they could not be turned.

It must be here noted that the comparisons above given are taken only as a general indication and not as absolute proof. It is only in connection with other experiments that these ideas are more clearly substantiated.

It now remains to consider the relation of the carbon in the above series. Unfortunately the writer has not had opportunity to distinguish the different state of the carbon in the different test bars, but it would seem from a comparison of the curves that much light would be shed upon the matter if this were done.

In a general way it will be noticed that the test bars containing the least carbon are a little higher, although the contrary will be noticed in particular cases. Thus SU#2, containing  $\frac{1}{2}$  per cent. more carbon than SU#1, is quite a little better than SU#1; the same may be said of SU#3.

These specimens examined under the microscope show a predominance of the structure indicating carbide carbon. The structure is strongly characteristic. The accompanying micro-photographs give a clear idea of them, although in the original the projection is highly coloured. The structure of all the members of this series shows a strong resemblance, but minor differences are noticeable.

Having noticed the results from this series, it seemed desirable to note the effect of manganese and sulphur. In order to discover whether manganese has a marked effect

on permeability, a hand ladle was filled from the regular dynamic cast-iron and a small amount of ferromanganese, containing about 85 per cent. of manganese, added. A test bar was then cast and about the same amount of ferromanganese again added, and another bar cast. The first bar contained 0.78 per cent. of manganese, and the second 1.76. The latter was considerably lower in permeability. It will be noticed, however, that the combined carbon has been doubled by the addition of the greater quantity of manganese, and this probably accounts for the lower permeability (see curves SU #17 and SU #18). Manganese in all probability effects the magnetic properties through its effect on the carbon.

PLATE IV.

This effect is largely governed by the content of carbon and the content of the other elements, particularly silicon. It is safe to say, however, that the influence of manganese plays a very small part when the content is below 1 per cent. This is especially true of high carbon irons, such as cast iron. In general, what is said of manganese may be said of sulphur, as far as the indirect effect is concerned. However, a very small quantity of sulphur has a very powerful effect; this is especially true in low carbon iron.

The experiments with sulphur were mostly carried on with a semi-steel containing from 40 to 50 per cent. of steel-rail scrap, and having a total carbon content of about 2 per cent., most of which was in the graphitic state. In these irons when the sulphur rose much over one-tenth of 1 per cent., it was nearing the danger limit, while 13 per cent. was fixed as the maximum for any metal of this composition where even moderate results were expected. It must be noted, however, that a soft graphitic carbon iron could carry this content without much detriment to its permeability. If the sulphur was increased in these high carbon irons a very bad effect is noticeable.

The effect of sulphur is undoubtedly indirect and effects the permeability through its power of promoting combined carbon. One of the test bars of semi-steel, containing about 0.15 sulphur, was so white and hard that it could not be turned, although the other constituents were normal, with the exception of the higher content of combined carbon.

If we return to our consideration of the effect of silicon on the magnetic properties of iron alloys, and consider another alloy of iron, we will find our deduction from the first series confirmed. The alloy selected for these tests was the semi-steel above mentioned, except that the sulphur content was normal.

It will be noted in the accompanying curve the relative position of the metal to cast iron and cast steel. With this alloy the silicon varied about  $\frac{2}{3}$  of 1 per cent., and some cases nearly 1 per cent., without any appreciable effect. A variation of  $\frac{5}{10}$  of 1 per cent. produced no effect whatever upon the permeability. The silicon in this alloy is always kept above 3.75 per cent., consequently, is always so high that the change in the content could scarcely affect the state of the carbon. However, it was found that the content of silicon had a marked effect on the hysteresis, the loss by

hysteresis being very much less when the silicon was high. A variation above 3.75 per cent. had an effect on the hysteresis, where none was noticeable on the permeability.

PLATE V.

It would seem fair to presume that silicon has no direct effect on permeability and above the limit necessary for holding the carbon in the graphitic state, it is doubtful if it has any effect. This is also probably true in the irons containing no graphite, but there would undoubtedly be a limit in this case.

In the same way phosphorus can vary greatly in this metal without any noticeable effect. Within the limits that have been experimented with, nothing has been noticed that would lead one to think that phosphorus has any effect on permeability or hysteresis. This limit is over 1 per cent., and covers the range that would be met with in commercial work.

The carbon is undoubtedly the chief factor in the chemical effect on permeability and hysteresis. Practically the same effects were noticed in the semi-steel as in the pot irons previously mentioned. In general a low content of combined carbon indicates high permeability and low hysteresis. It is often noticeable, however, as in the case of the pot irons, that an iron containing more combined carbon than another would have a higher permeability. To discard physical effects this is readily accounted for by the different state of the carbon.

It has occurred to the writer that there was some form of combined carbon that varied in these irons, and the permeability was more affected by the content of this form of carbon than by the total content of combined or graphitic carbon. This form of carbon seems to be that which Prof. Ledebur calls hardening carbon, and is probably the complex crystalline mass isolated by the microscopist under the name of Martensite. Although not having opportunity to investigate this question further, from the meager data at hand, on this phase of the question, it would seem that this is the state of carbon having the most influence in the different varieties of iron in which permeability and hysteresis are important. This is offered merely as a suggestion and the writer has hopes of investigating the matter further.

Graphite appears to act as an inert body in regard to magnetic qualities. In the irons where its content is one of the predominating elements, a considerable variation is often noticed without much variation in the permeability. Its effect is that of an inert body except it tends to open the grain of the metal and thereby decreases the density,

which of course effects the permeability. In the case where an attempt is made to close the grain of cast iron for the purpose of raising the permeability, the permeability is more often lowered than raised. While the graphite may be decreased in this way and the density of the specimen raised, the beneficial effects are absent for the reason that the combined carbon is increased and the permeability is lowered by its effect. If the graphite can be decreased without raising the content of combined carbon, the permeability will unquestionably be higher.

PLATE VI.

To show the radically different structure of the different specimens discussed in this paper, some micro-photographs will be found of some of the principal alloys. The photograph marked No. 6 is a permanent magnet made of cast

No. 1 (SU#8).

iron. It is very high in combined carbon. Its structure after etching more closely resembles steel than any of the other irons. The complex formation of this iron is quite apparent. The sample has been hardened, after it was cast, thereby increasing the percentage of combined carbon. Its structure is quite unique compared with the other irons.

The graphite in the photographs of cast iron and semi-steel show very clearly the predominance of this metalloid in these metals. No. 5 illustrates the structure of the test bar giving the curve marked 50—3 and it is one of the highest cast irons examined.

The other photographs are of the special pot metals and are very characteristic and unique. They show very

No. 2 (SU#5).

No. 3 (SU#2).

closely the effect of the high combined carbon content. The structure is characteristic of the carbide form of carbon which predominates in all of these pot metals.

Photographs 2 and 7 are of test bar which gave the curves SU#5, and SU#3, which curves are identical throughout their range. The minor differences in structure are probably due to difference in etching conditions.

No. 4 (SEMI-STEEL).

No. 6 (CAST IRON.—PERMANENT MAGNET).

No. 7 (STEEL).

The physical state of the metal is equally or more potent in its effect upon the magnetic properties of iron, and it is this effect which makes deduction from experiments on chemical effects more or less general. An almost carbonless iron will often be found of low permeability and high hysteresis in comparison with its class. After it is annealed, it will sometimes give results very much better than its class. This seems to be due to an internal stress

which has resulted from some heat treatment, and inasmuch as the specimen is nearly pure iron it must be purely physical. This might be attributed to an allotropic state of iron similar to that proposed by Prof. Osmond, of France, but whatever be the facts, the physical condition of the metal must ever play an important part in calculations of this kind. It does not, however, make the chemical study useless. It is often surprising to note how closely one can figure from chemical results, and the chemical study of these irons have been of high commercial importance where it has been pursued.

#### SULPHURIC ACID AS A REAGENT IN THE ANALYSIS OF FATTY ACIDS.

BY E. TWITCHELL.

WHEN concentrated sulphuric acid is brought in contact with any fat, a decided chemical action is observed. This reaction appears to involve chiefly the unsaturated fatty acids of the fat, and consists primarily of the addition of  $\text{H}_2\text{SO}_4$  to the unsaturated carbon atoms of these acids. The products of this combination have been studied to some extent, and have found some practical uses; notably in dyeing and calico printing with Turkey red. It is not to the commercial uses of these bodies, which I believe are destined to greater importance in the manufactures, that I wish to call your attention, but to the possibility of developing exact methods for the analysis of fats by the aid of concentrated sulphuric acid.

I do not know that any attempt has been made to employ sulphuric acid as a reagent in any of the quantitative methods which have of late become of such importance in the examination of fats. The nearest approach to such a method is the Maumené thermal reaction, which, indeed gives remarkably exact results considering the imperfect apparatus and manner of manipulation usually employed. The object of this process is clearly to measure the heat of combination of the sulphuric acid with the two or more unsaturated fatty acids of the fat. A thermal effect as definite as this would imply a definite chemical reaction as a cause, and this strengthened my belief that quantitative results could be obtained from the action of sulphuric acid on fatty acids. If this were the case, then a separation of the unsaturated oleic, linoleic, and linolenic acids from the unacted on, saturated palmitic and stearic acids could be obtained, and possibly a difference in the action of sulphuric acid on the different members of the groups of unsaturated acids might show itself. With this in view, the following work was undertaken, during the course of which I observed some peculiarities in the manner in which sulphuric acid acts on these bodies, as well as some properties of the resulting compounds, which I do not think have been published before. For this reason a somewhat detailed description is given of some of my preliminary experiments which, from the analyst's point of view, are failures, but which brought out some of the characteristics of these interesting compounds.

At ordinary temperatures, or even at  $100^\circ \text{C}$ ., concentrated sulphuric acid has no effect on the saturated fatty acids of ordinary fats. Experiments with pure palmitic and stearic acids have satisfied me as to this. It, however, combines with oleic acid at very low temperatures, and its action on linoleic acid must be very similar to that on oleic acid, as some of my experiments with mixtures which undoubtedly contained large quantities of linoleic acid, would indicate.

When sulphuric acid acts on oleic acid at not too high temperatures a compound is formed which has been studied by various chemists and was supposed to be a sulphonic acid, sulpho-oxy-stearic acid—

Later Benedikt has shown that it is more probably a sulphuric ester of oxy-stearic acid, stearo-sulphuric acid,  $\text{C}_{15}\text{H}_{31}\text{CH}_2\text{CH}(\text{HSO}_3)\text{COOH}$ . This will be seen to be the sum of 1 mol. of oleic and 1 of sulphuric acid. This substance has properties which should make its separation from the fatty acids comparatively easy. It is readily soluble in water. It is a strong acid, dibasic; the acid hydrogen of the  $\text{HSO}_3$  group being comparable in strength

with that of sulphuric acid itself, while the hydrogen of the carboxyl group has the properties of that of other fatty acids. This fact furnishes a simple and beautiful method of examining and identifying compounds of this nature, as the  $\text{H}_2\text{SO}_4$  group can be sharply titrated with standard caustic soda solution, using methyl orange as indicator, and then phenolphthalein can be added and the carboxyl group accurately titrated. The acid strength of this compound is shown by another remarkable property. If the aqueous solution of stearo-sulphuric acid be salted out with common salt or sodium sulphate the pure compound is not obtained, but large quantities of the sodium salt are formed by double decomposition between the stearo-sulphuric acid and sodium chloride or sulphate, and this even in quite an excess of mineral acid. This fact has been noted by Duillard in his investigation of Turkey-red oil.

I have found also that compounds containing the  $\text{H}_2\text{SO}_4$  group are entirely insoluble in petroleum ether, provided no large quantity of fatty acid is present. This last property has proved to be the most useful in purifying these compounds. At first thought it would appear that their solubility in water would furnish a most simple means of separating them from the quite insoluble fatty acids; but it was found that this aqueous solution was a very good solvent for most fatty matters, and, besides, had a strong tendency to form emulsions with the ether or other medium with which it was shaken, thus rendering the separation very tedious. When petroleum ether is used the sulphuric acid compounds need not be dissolved in water, but can be extracted dry, or floating on an acid solution in which they are insoluble.

With the aid of petroleum ether it was attempted to separate from the products of the action of sulphuric acid on a fatty acid mixture that part unacted on. If the combination with the unsaturated acids were complete, this unacted on part would be the saturated stearic and palmitic acids, at least in the case of the more common fats, and we would then have a simple method for the separation of these from oleic and other liquid acids.

To determine the completeness of the reaction, experiments were made with oleic acid. No attempt was made to obtain this absolutely pure, but the commercial product, which had been pressed at a low temperature, was made use of. It had a cold test of  $12^\circ\text{C}$ , and could contain but little solid fatty acid. On treating this oleic acid with about twice its weight of 94.7 per cent. of sulphuric acid, adding the acid slowly to avoid rise of temperature, a clear solution was formed. To this was then added an equal volume of water, still keeping the temperature as low as possible with ice water. The whole was then shaken with petroleum ether, which was decanted and evaporated, leaving a residue which, in two experiments, was found to be 49.51 and 42.31 per cent. of the oleic acid taken. This was liquid at the temperature of the room, and slightly more viscous than the original oil. Its mean combining weight, as found by titration with caustic soda, was 328. It was found to contain no sulphur. The oily layer insoluble in petroleum ether was identified as stearo-sulphuric acid, and but little over one-half the oleic acid had been converted to this compound.

As the petroleum ether extract of the last experiment was not simply oleic acid, but gave unmistakable evidence of having been acted on by the sulphuric acid, it seemed possible that the reaction between oleic and sulphuric acids, in the first place, was complete, but that, on adding water, a part of the  $\text{H}_2\text{SO}_4$  compound was instantly decomposed, yielding the substance soluble in petroleum ether. To decide this point, an attempt was made to extract with petroleum ether the sulphuric acid solution of a fatty acid without adding water; but in no case could anything be removed from the solution, even when a fatty acid was used which was known to contain saturated compounds. It appeared that the solubility of all fatty acids in concentrated sulphuric acid was so great that they could not be extracted from it by petroleum ether.

The following experiment is conclusive:—One  $\frac{1}{2}$  gram. of a sample of fatty acid, containing about 40 per cent. of stearic and palmitic acids, was dissolved in 50 c.c. of petro-

leum ether, and thoroughly shaken with 4 c.c. of 95 per cent. sulphuric acid. It was found that all but 0.02 grams of the fatty acid had been removed from the ether by this one treatment with so small a quantity of sulphuric acid.

The simplest way to diminish the solvent action of sulphuric acid on the solid fatty acids would be to slightly dilute the former, and if at the same time it remained of sufficient strength to act on the oleic acid, the separation could be undertaken with more hope of success. A number of preliminary experiments led to the conclusion that sulphuric acid of 85 per cent. acted on oleic acid quite as completely as the stronger acid, while stearic and palmitic acid could be readily shaken out of this solution with petroleum ether. Moreover, the rise in temperature was much less, and the mixture could be made without any particular caution.

I now repeated the last experiment with oleic acid, using, however, 85 per cent. of sulphuric acid instead of the more concentrated. A description in detail of this experiment will perhaps best bring out its object and the conclusions to which I arrived.

In a glass-stoppered Erlenmeyer flask of about 300 c.c. capacity was weighed 2.0785 grams of oleic acid. This was spread over the bottom of the flask and chilled by dipping the flask in ice water. To this was then added 1 c.c. of 85 per cent. sulphuric acid, and the flask allowed to warm in the air. As soon as the oil began to melt the sulphuric acid acted and a clear solution was formed, though without any appreciable disengagement of heat. 50 c.c. of petroleum ether was now poured into the flask, which was well closed, and violently shaken for a few minutes, allowed to settle, and the ether decanted. The contents of the flask were again shaken with 50 c.c. more of petroleum ether. The two extracts were then each transferred to a separatory funnel washed with water to remove any sulphuric acid which they might contain, and separately evaporated. The following residues were obtained:—

1st extract .....	0.0680 gram.	= 4.71 per cent. of the oil.
2nd " .....	0.0530 " "	= 2.55 " "

The first extract had a melting point of  $37^\circ\text{C}$ , and was therefore not pure stearic and palmitic acid, though it had the crystalline appearance of a mixture of these acids. The second extract was liquid at the temperature of the room, and could contain but little solid fatty acid. Continuing the treatment with petroleum ether, there was always a small quantity of oily substance taken up from the sulphuric acid solution. A more careful examination of this extract made it appear that the petroleum ether had taken up a small quantity of the stearo-sulphuric acid, which on treatment with water was partially dissolved out, while a part decomposed, which we have seen always happened to this compound on adding water. This part went into the petroleum ether solution and gave these small residues.

It is therefore highly probable that sulphuric acid of 85 per cent. acts quantitatively on oleic acid to form stearo-sulphuric acid, which is sufficiently insoluble in petroleum ether to allow of an analytical separation from those fatty acids on which sulphuric acid has no effect.

It now remained to apply this method to fatty acids containing considerable quantities of saturated compounds. Before giving figures I will briefly describe the manner of manipulation which I have adopted for the present:—From  $\frac{1}{2}$  to 1 gram. of the fatty acid to be analysed is weighed in a glass-stoppered Erlenmeyer flask, melted, and by moving the flask, chilled in as thin a layer over the bottom as possible; this to facilitate the action of the sulphuric acid by exposing a large surface. On the layer is now poured about 3 c.c. of 85 per cent. sulphuric acid. There is usually no combination until the flask has been slightly warmed. At a certain temperature the combination takes place very rapidly and forms a clear solution. When this occurs the flask is quickly cooled, 50 c.c. of petroleum ether added, the stopper inserted and the flask shaken violently for a minute or two, then allowed to settle and the petroleum ether decanted. The flask is rinsed twice, each time with

10 c.c. of petroleum ether. The washings are added to the first extract and the whole poured into a separatory funnel and washed once or twice with water. The petroleum ether is then evaporated, and the residue, consisting of the saturated fatty acids weighed. The results of the analysis of a few samples of fatty acids are given in the following table:—

Origin of the Fatty Acids.	Solidifying Point.	Amount used.	Petroleum.	Ether Extract.	Melting Point of Saturated Acids.
		Gram.	Gram.	Per Cent.	°C.
Lard.....	49.75	0.7845	0.5316	42.35	53.5
Cotton-seed oil	34.80	0.6450	0.2005	32.60	..
"	31.20	0.5875	0.1465	23.91	53.0

The solidifying points of the original fatty acids are given as an imperfect criterion of what may be expected as to the percentage of solid fatty acids they contain. The saturated acids, being in very small quantity, their melting points were obtained by heating in a small tube attached to the bulb of a thermometer; the point taken was that of incipient fusion, which I have found to correspond quite closely to the solidifying point obtained with larger quantities. As the solidifying point of the composition of stearic and palmitic acids contained in these fats is about 55° C., the melting point shown would indicate a slight impurity.

To decide whether the extraction of the unacted on fatty acids had been complete, the sulphuric acid solution of the last sample of cotton-seed oil fatty acid was shaken a second time with 50 c.c. of petroleum ether. By this treatment 0.0190 grms. were obtained, which, however, did not solidify at the temperature of the room, and, from the former experiment, I concluded to be the decomposition product of a small quantity of stearo-sulphuric acid taken up by the petroleum ether.

The figures of the table lead to another conclusion, namely, that linoleic acid is acted on quite as completely as oleic acid to form a compound insoluble in petroleum ether. This is proved by the completeness of the reaction with cotton-seed fatty acids which, if we can trust the iodine absorption test, must contain from 40 to 50 per cent. of linoleic acid. Beyond the insolubility in petroleum ether, I have as yet investigated none of the properties of the compound of linoleic acid with sulphuric acid.

A few words as to the petroleum ether employed: the commercial product even after redistillation contains compounds which, when brought in contact with concentrated sulphuric acid, form products not volatile on the water-bath. When acid of 85 per cent. is used, there is not so much action, but it will be well always to test the petroleum ether by shaking with 85 per cent. sulphuric acid, separating and evaporating on the water-bath. If there is a residue, the ether should be purified by digesting for an hour at 100° C., with about one-half its weight of concentrated sulphuric acid, then washing and redistilling on the water-bath.

The method described will, I believe, be found useful in the analysis of fats, both in the examination of the natural bodies, and as an assay of raw materials and intermediate products in the manufacture of commercial stearic acid. That the saturated fatty acids obtained by this method are not absolutely pure, cannot be denied, but this impurity is of such a nature that it is quite possible a means may be found for its accurate separation or estimation.

If this can be accomplished, we shall have a stricter accurate method for separating two groups of fatty acids, something much needed in the development of the chemistry of the fats.

## I.—PLANT, APPARATUS, AND MACHINERY.

*Liquid Ammonia Cylinder, Cause of the Explosion of a.* H. Lange. *Woch. für Brau.* 1897, 14, [15], 584—585.

In the course of the investigation on the explosion of a cylinder of liquid ammonia used in connection with an ice-making machine, it was found that the cylinder had been placed in a vessel of water heated by steam, and that the valve had been left closed, thus causing a high pressure of gas and expansion of the liquid. All such cylinders in Germany are tested up to a pressure of 100 atmospheres, and must not contain more than 1 kilo. of ammonia in a space of 1.86 litre.

With the object of avoiding the danger of warming the cylinders, the author advocates the introduction of the ammonia as liquid instead of gas into the freezing apparatus.—C. A. M.

*Painted Ironwork, Rusting of.* E. Simon. *Dingler's Polyt. J.* 1897, 305, 285.

### PATENTS:

*Licciating, Steaming, and Aërating, Impts., in.* J. Hargreaves, Farnworth-in-Widnes, Lancashire. *Eng. Pat.* 23,263, Oct. 20, 1896.

Liquid, vapour, or gas is passed downwards through a series of vessels containing the materials to be treated, each newly-charged vessel being introduced at the bottom or lower part of the series, then gradually raised as each similarly charged vessel is introduced beneath, and ultimately removed when it arrives at the top of the series.

—R. A.

*Drying Granular and other Material, Impts. in Apparatus for.* C. G. J. Moeller, Berlin. *Eng. Pat.* 25,612, Nov. 13, 1896.

The furnace or other gases employed in the drying process, after they leave the material which is being dried, are conducted back by means of a fan, through a return channel or flue, and are mixed with fresh combustion gases as they issue from the furnace. By this method, the temperature of the

\* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to C. N. Dalton, Esq., Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

gases arising from the fire is reduced, whilst avoiding loss of heat, and only as much air is conducted through the furnace as is requisite for the advantageous combustion of the fuel. Several forms of the apparatus are described in the specification, some of which comprise a series of heating registers, which are heated by the warm gases issuing from the drying apparatus, and are saturated with the condensed steam, these registers again yielding up their heat to the fresh air entering the apparatus. The registers thus serve the purposes of utilising the free and latent heat of the exhaust gases, and of collecting the condensation water.

—R. A.

*Filtering, Washing, and Drying Crystalline, Granular, and other Materials; Impts. in the Method of and Apparatus for.* S. Sherratt and W. A. Richards, both of Northwich, Cheshire. Eng. Pat. 28,289, Dec. 10, 1896.

THE material to be treated is delivered on to a rotating filter bed in the apparatus, with or without the addition of water or other washing fluid, and the liquid is drawn through the material on the filter by means of a vacuum apparatus beneath. When it is necessary to subsequently dry the material, air or gas, heated or otherwise, is drawn through the material in the same manner. The latter is removed from the filter bed by a number of curved scrapers, which can be lowered to, or raised from, their operative position either automatically or by hand.—R. A.

*Sand, Cement, and other Similar Substances; Impts. in Apparatus for Measuring and Mixing.* H. Alexander, Water Lane, Leeds. Eng. Pat. 13,505, June 1, 1897.

THE apparatus comprises a compound hopper, having separate divisions for receiving the different materials to be mixed, in combination with a compound drum, having separate sets of adjustable compartments for measuring the materials and delivering them into a mixing trough below. In the trough, the materials are mixed by two sets of oppositely-rotated mixing blades.—R. A.

*Preserving Organic Bodies, Impts. in Apparatus for.* L. A. M. D. de Belfort, Paris. Eng. Pat. 14,907, June 19, 1897.

THE apparatus consists of a number of steel cylinders lined with lead, capable of withstanding a pressure of several atmospheres. These are connected by pipes with each other, and also with a carbon dioxide generator. The materials to be preserved are placed upon shelves in the cylinders, which are then charged with carbon dioxide under a pressure of 5 to 10 atmospheres. After about 15 minutes, the carbon dioxide is displaced by pumping in water containing 0.25 per cent. of formalin in solution. After about 30 minutes the solution is run off, and the articles are removed from the cylinder. Polymerisation of the formalin is prevented by the addition of from 25 to 30 per cent. of common salt or other normal chloride, and when preservation for several months is desired, the liquid, whilst in the cylinder, is subjected to electrolysis, to increase its antiseptic properties.—L. A.

## II.—FUEL, GAS, AND LIGHT.

*Flame, Non-Transparency of Glowing Carbon in.* N. Techn. J. prakt. Chem. 1897, 56, [15, 16], 178—180.

HUX (Ann. Chim. phys. 30, 319), not being able to prove optically the presence of finely-divided carbon in the luminous gas flame, concluded that at a high temperature, the solid particles become transparent. To determine this point the author made experiments with different flames. The ordinary gas flame, Bunsen flame, and flames of a candle and petroleum lamp, together with the glowing carbon thread of an incandescent lamp were illuminated by electric light, their shadows projected on a white screen and photographed. In the photographs (reproduced in the paper) there was no perceptible difference between the shadows cast by the luminous and non-luminous gas flames, and the same was the case in the shadows cast by sunlight. In the shadow of the candle flame a darkening was faintly visible, and markedly so in the case of the

petroleum flame. The shadow cast by the glowing carbon thread was scarcely visible, but became plainly visible in oblique light.

Experiments were made to determine whether there was any difference in the transparency of the gases likely to be present. The shadows cast by layers (of a metre) of carbon monoxide, carbon dioxide, coal gas, acetylene, and air sealed in glass tubes showed that the gases differed but little in this respect.

Considering that the difficulty of optically recognising suspended particles in the gas flame was due to their extraordinarily fine state of division, the author experimented with a thicker layer of burning gas. Twelve batwing flames, 3 cm. broad, were placed one behind the other and illuminated as before with the electric light. The shadow cast on the screen showed very plainly a dark zone, which, in the author's opinion, could only be due to the presence of solid particles. Hence, he considered that Hux's conclusion was due to his method not being sufficiently sensitive, and that therefore the theory of the transparency of carbon in glowing condition was not justified by the facts.—C. A. M.

*Coal-Gas, Action of Sulphuric Acid on.* P. Fritzsche. J. f. prakt. Chem. 1897, 56, 258—265.

Brown substances, ranging in consistency from resin-like solids to limpid oils, are formed when coal-gas is washed with concentrated sulphuric acid. Berthelot (Comptes Rend. 82, 871) obtained 25 grms. of such condensation products from 100 cb. m. of Paris gas, and thence isolated six bodies of an aromatic nature, apparently formed by condensation of the molecules of methyl-, dimethyl-, and propyl-acetylene. The acid would therefore appear to exert only a contact action on the hydrocarbon, but the author found the volume of the products scarcely diminished when substituted acetylenes were removed from the gas by means of ammoniacal cuprous chloride prior to the washing with acid. Therefore Berthelot's explanation can only apply to a small part of the condensation products. Moreover, the quantity and nature of the products vary with different samples of gas. The author obtained from 5—15 grms. per cb. m. of gas. A portion was dissolved by water, forming a green solution; and, after washing the remainder with solution of potash, about three-fifths of the whole was susceptible of distillation, and passed over steadily between 100°—300° C. Several kilos. were prepared by treating coke-oven gas—freed from benzol and sulphuretted hydrogen—with sulphuric acid under five atmospheres pressure. The brown oil which remained after some crystals had deposited, was washed with slight excess of caustic soda, and the saline solution was separated from oil and concentrated. On cooling, white scales of silky lustre were detected in the dark brown pulp, and by repeated extraction and crystallisation this white salt was separated. From it other salts were prepared. The chief characteristics of the salts are as follows:—

The copper salt,  $(C_{15}H_{25}SO_4)_2Cu + 6H_2O$ , prepared from the sodium salt and copper sulphate, is pale blue, but, when dehydrated, pale green. The salts of the alkalis latter freely, and dissolve phenols to clear non-alkaline solutions. The ammonium salt,  $C_{15}H_{25}SO_4NH_4 + 2H_2O$ , is in needles of silky lustre, readily soluble. The sodium salt,  $C_{15}H_{25}SO_4Na + 6H_2O$ , forms efflorescent plates, less soluble than the ammonium salt, and fuses only with decomposition. The alkaline earths give salts with difficulty soluble in cold, more readily in hot water. The ferrous salt,  $(C_{15}H_{25}SO_4)_2Fe + 7H_2O$ , is white—yellowish in a moist atmosphere. This salt separated in crystals from the original condensation product, the iron having been derived from the containing vessel.

The acid was prepared by passing sulphuretted hydrogen through water containing the copper salt in suspension, and removing the copper sulphide. It formed white crystals, readily soluble, and was very stable, being unattacked by hot concentrated sulphuric acid, and liberating hydrochloric acid from a hot solution of common salt. In this respect it resembles the sulphonic acids derived from the camphors, and it appears to be the sulphonic acid of a body having the formula  $C_{15}H_{25}O$ , which is also that of cedar-camphor.

Other acids of a similar nature appear to be present in the condensation products of gas. The mother-liquor of the above sodium salt contains at least one other acid, probably several acids, of which the salts are more freely soluble. On distilling the clear brown oil remaining after washing the condensation product with alkali and water, a crystalline white body was obtained at 200—220°, but was not examined. The distillate oils boiling below 200 were limpid, and left a grease spot on paper; those boiling between 200 and 300° resembled mineral oils. The hydrocarbon residue in the retort cooled to a brown resin. Clearly, the products of the treatment of coal-gas with sulphuric acid are by no means so simple as Berthelot supposed.—J. A. B.

#### Gas Lamps, Incandescent; Danger of Fire from.

Dingler's polyt. J. 306, [4], 96.

A NOTIFICATION has recently been issued by the Chief of Police in Berlin, to the effect that, in consequence of the frequency of fires due to the ignition of wooden beams in buildings by the flame of incandescent gas lamps, situated too close to the ceilings or beams, such lamps—which give out a greater amount of heat than is, apparently, generally supposed—must in future be placed at least 40 ins. from the ceiling, or else fitted with a (sufficiently large) shield to protect the woodwork. Such shield must, however, not be affixed to the ceiling, but either attached to the lamp or else suspended from an adjoining brick wall.—C. S.

#### PATENTS.

Fire-Damp in the Atmosphere of Mines and other Places [Gas Battery], Improved Method of and Apparatus for Detecting and Indicating the Presence of. E. L. Mayer, London. Eng. Pat. 23,822, Oct. 26, 1896.

See under XXIII., page 1040.

Calcium Carbide, Manufacturing, and for the Reduction of Metals from their Oxides; An Improved Method and Apparatus more especially intended for. H. Maxim, London. Eng. Pat. 25,611, Nov. 13, 1896.

See under XI. B., page 1022.

Peat-Charcoal, Impts. relating to the Production of, and to Apparatus therefor. E. T. Zohrab. Eng. Pat. 26,191, Nov. 19, 1896.

RELATES to the preparation of weathered peat charcoal, especially useful in blast and other furnaces in the production of iron, steel, or other metals. There are three steps in the process, and three sets of apparatus.

1. *Pulping*.—The peat is passed into a vertical perforated inverted hollow cone, having a tapered Archimedean screw, whereby the peat is forced through the perforations to a lower vertical cylinder, where it is subjected to the action of rotating and fixed knives, and forced through lower openings into horizontal tubes, also provided with Archimedean screws and rotating knives, which force the pulp through perforated end plates, to suitable moulds for forming blocks.

2. *Drying*.—The blocks are fed to the top member of a series of endless bands, arranged in a drying oven, so that the blocks are continually and slowly moved forwards from one end to the other of the top band, then, falling to the next lower band, travel backwards, and so on to the lowest band.

3. *Charring*.—The dried blocks are filled into a box on wheels, and run into a kind of muffle furnace. The gaseous products are collected in a hydraulic main.—R. S.

Enamelling Process, Impts. in, for Electric Heating Apparatus. [Insulation.] R. E. B. Crompton and E. J. Fox, London. Eng. Pat. 26,267, Nov. 20, 1896.

To prevent the resistance wire coming into contact with the metal plate in electric heating apparatus manufactured according to Eng. Pat. 17,091, 1892 (R. E. B. Crompton), the plate is first given a thin coating of enamel, and while this coat is still in a plastic condition, it is covered with a layer of granulated porcelain, or similar infusible and non-conducting substance, which is again covered with a layer of enamel, and the whole fired together. The resistance wire is then attached as described in the previous patent. When very great insulation is required at very high temperatures, the layer of granulated material is replaced by a thin sheet of porcelain, or similar substance, which may be either continuous or moulded into hexagons or other convenient forms, which can be laid closely side by side, and is then covered with a layer of enamel.—G. H. R.

Electric Furnaces, Impts. in. [Fixed Arc.] W. S. Horry, Michigan, U.S.A. Eng. Pat. 22,521, Oct. 1, 1897.

THE furnace consists of a bottomless hopper of fire-resisting material, supporting standards so as to hang over the space between the carbons in which the arc is struck, and between the flanges of a rotary spool or reel, to which movable cover plates can be attached. The carbons rest on the fire-proof material of the hopper, which screens their electrical connections from the heat of the furnace, and their edges are bevelled so that the space between them is vertical. The length of the arc is constant, and not variable, as in previous furnaces. A mixture of the coke and lime is fed into the hopper and converted into calcium carbide in the arc, and when the ampèremeter rises, the spool is rotated to remove the product from the furnace, the action of which is thus continuous, fresh material being fed into the hopper as that converted into calcium carbide is removed in a plastic sheet.—G. H. R.

Heating or Evaporating by means of Hydrocarbon Liquids of any Density, Impts. in Apparatus for. P. J. E. E. Chambost, Paris. Eng. Pat. 29,000, Dec. 17, 1896.

THE hydrocarbon liquids are passed through an externally heated horizontal retort or cylinder, provided with a central shaft on which are a number of partitions. Within this retort the hydrocarbon is vaporised, the coke being deposited in the retort, which is purposely arranged so as to be easily taken apart for cleaning. Preferably, two retorts are used, so that whilst one is in use the other is being cleaned. The vaporising retorts are enclosed within one or more refractory and non-conducting jackets, to prevent loss of heat. Part of the vapours may be used to heat the retorts, the rest being employed for the special heating device for which it is required. The burpers used for these vapours consist of a valve-box, in the bottom of which are one or more holes for the escape of the vapours. A perforated thin screwed cap preferably forms the bottom. The regulating plug has one bearing in this screwed cap, the other in a stuffing-box.—R. S.

Oil Burners applicable for Incandescent Lighting, Impts. in. W. P. Thomson, London. From The Continental Gas Glühlicht Actien Gesellschaft "Meteor," vormals Kroll, Berger, and Co., Berlin. Eng. Pat. 28,853, Dec. 16, 1896.

THE patentee claims an oil-lamp burner, which produces a blue flame suitable for incandescence lighting, as the result of four distinct air currents, *viz.*, a sluggish current rising inside the burner tube and passing to the outside over the edge of the circular wick, to develop therefrom combustible gas; a second current rising outside and past the outer edge of the wick, to carry the gas upwards; a third current of comparatively large volume rising centrally and being deflected to enter the flame at the point where it burns; and, finally, a fourth current rising outside of the second current and commingling with it, to change the direction of the combined other currents. The form of lamp preferred is of the Argand pattern, within the central air tube D of

which is fixed an inner tube A of smaller diameter, having a flange A' projecting over the wick, and a head with upper cover C and perforated sides for the escape of the general

air draught. Only a relatively narrow annular space is left between the tubes A and D, so that only a sluggish current passes outwards over the wick. A strong current passes between a cone E and the wick tube, and through the perforations in an outer cone G, there passes the above-mentioned fourth current from the base of the chimney.

—H. B.

**Incandescent Lighting or Heating Purposes, An Improved Vaporiser for Liquid Combustibles for.** F. V. C. Brokk, Berlin. Eng. Pat. 28,290, Dec. 10, 1896.

THE vaporiser claimed, consists of an annular retort containing a wick, from which hydrocarbon vapours are distilled off by a small central heating flame, the vapours mixing with air and burning beneath a mantle as usual. The waste gases of the small flame escape by a pipe which rises centrally through the vapour nozzle, the burner-tube, and the mantle, and as it is always hot throughout its length, it prevents the condensation of the vapours surrounding it. The annular retort is perforated with one or two passages, to admit air to the heating flame and to serve for igniting the flame, the passages being opened or closed by means of a revolvable ring.—H. B.

**Incandescent Burners, Impts. in.** A. Bandsept, Brussels. Eng. Pat. 29,597, Dec. 23, 1896.

IN the improved burner a central gas jet issues from a nozzle, the interior of which becomes gradually constricted. A little below its orifice the nozzle is surrounded by an annular gas passage or by a number of annularly arranged gas jets. The gas is directed upwards into a truncated conical chamber, at the base of which air is drawn in and mingles with the gas. Issuing upwards from this chamber the gas ascends a gradually widening tube, drawing a second supply of air from apertures at its base. The top of the expanding tube, forming the mouth of the burner, is covered with wire gauze, from the centre of which depends an inverted deflecting cone. The air-inlets may be regulated by a ring-valve, the expanding tube may be adjusted as to height by a telescopic arrangement, and to more effectively mix the gas and air, the deflecting cone may be lengthened and fitted with helical blades.—H. B.

**Incandescent Oil Lamps, Impts. in and connected with.** M. Graetz, Berlin. Eng. Pat. 29,697, Dec. 24, 1896.

IN a petroleum incandescence lamp . . . the combination is claimed with a duplex burner and with a device for raising the upper part of the said burner and fixing it in its raised position, of a means for detachably securing the upper part to the elevating device; of a flame-disc

situated in the plane of the upper opening of the cap of the upper part of the burner, and a cylinder supported by said part, and having at least twice the diameter of the wick tube; also of the means for holding the mantle above the flame.—H. B.

**Incandescent Oil Vapour Burners, Impts. in.** M. Bornstein and M. Ehrenbacher, Berlin. Eng. Pat. 24,913, Sept. 24, 1897.

WITHIN a circular wick is arranged a central shaft, up which a current of air passes, the air being heated by passing through a concentric radially disposed system of thin metal plates. The primary flame, burning at the top of the wick, is divided into "a number of separated, heating and illuminating flames," by feeding the combustible mixtures through a perforated flame distributor which is surmounted by a perforated hollow cap, in which part of the mixture is superheated. The superheated mixture blows outwards against the exterior flame circle, meeting with a supply of air which has been previously heated by passing through a perforated hollow metal casing. The burner is surmounted by a mantle as usual.—H. B.

**Carburetted Air for Incandescent Gas Light, Process and Apparatus for the Production of.** O. Kabus, Hamburg. Eng. Pat. 20,571, Sept. 7, 1897.

CARBURETTED air for incandescent gas lighting is produced by leading a current of air through a closed tank in which are suspended partitions of wick-like, absorbent fabric, kept saturated with a hydrocarbon liquid. This hydrocarbon liquid may be a cheap product of the process of petroleum refining, having a sp. gr. of 0.71.—H. B.

**Acetylene Gas, Impts. in the Production of, and in Apparatus therefor.** L. N. V. Bablon, Paris. Eng. Pat. 25,224, Nov. 10, 1896.

A DISTRIBUTING screw at the base of a receptacle for ground carbide is rotated by a gas meter through which passes the gas flowing from the holder to the burners, and the carbide falls into water and produces acetylene at a rate determined by the speed of rotation of the screw. The rise and fall of the holder may control a variable speed gear or a friction clutch device between the meter and the distributor. Or the meter may directly operate the distributor, and the holder control an outlet valve on the carbide receptacle, or a valve on a by-pass main, which permits gas in case of over-production to slip the meter.

—J. A. B.

**Acetylene Gas, Impts. in Apparatus for Generating.** J. Wetter, London. From G. Meyer, Zürich. Eng. Pat. 27,212, Nov. 30, 1896.

WATER is discharged from a chamber into a generating vessel containing carbide, when the gas-holder descends, and, by means of lugs, releases a weighted lever which opens the discharge valve. The water at each discharge barely suffices to generate sufficient acetylene to fill the holder. The water chamber is refilled automatically, and is provided with an overflow pipe.—J. A. B.

**Acetylene Gas, Impts. in or relating to means for Regulating the Production of, and in Lamps therefor.** E. Gossart and H. Chevallier, both of Bordeaux, Gironde, France. Eng. Pat. 27,574, Dec. 3, 1896. (Under Internat. Convention.)

AN auto-regulating lamp is formed of a base containing a basket in which is calcium carbide, on which drops from one or more capillary tubes—bent to increase their length in a small compass—water from a cistern forming the cover.—J. A. B.

**Acetylene Gas, Apparatus for Producing.** E. Richard-Lagerie, Roubaix, France. Eng. Pat. 29,168, Dec. 19, 1896.

IN the crown of a bell gasometer is arranged a bell-shaped receiver submerged in water in an annular tank fixed to the gasometer crown. A pipe with cocks places the bells in communication. A carbide basket covered by an inner

bell-shaped receiver acting as a float: is fixed by bolts in the outer bell-shaped receiver. The water in the gasometer tank serves for the reaction, which ceases when the pressure in either bell increases and lifts the carbide above the water.—J. A. B.

*Acetylene Gas, An Improved Apparatus for the Production, Drying, Purifying, and Storage of.* W. H. Dargue. Newcastle-on-Tyne. Eng. Pat. 29,768, Dec. 28, 1896.

The generator is cylindrical and is water-jacketed, or within the water tank of a bell gasholder, whence, or from an independent cistern, water is supplied to the carbide under the control of a valve operated by the movements of the bell. Suitable connections and taps for relief generators are described.—J. A. B.

*Acetylene Gas, Apparatus for Producing.* G. Lebrun and E. Cornaille, Paris. Eng. Pat. 512, Jan. 7, 1897. (Under Internat. Convention.)

Water from a closed reservoir falls on to carbide in a wire-gauze cylinder, which is mechanically rotated above a tray for the reception of the residual lime. The flow of water is determined by the pressure of gas admitted to the top of the reservoir by a pipe, on which is a valve controlled by the movements of the gasholder into which the acetylene passes.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for the Production of.* W. P. Thompson, Liverpool. From P. P. H. Macé and L. L. H. Gérard, both of Paris. Eng. Pat. 3013, Feb. 4, 1897.

IN the crown of the weighted and balanced bell of a gasholder is fixed a carbide receptacle, provided with a discharge opening of a doubly tapering form. Two cones on a weighted and guided rod act, one above, the other below, this opening, and open and close it in concurrence with the falling and rising of the bell, which arrest and release the rod. Pulverulent carbide falls through the opening into the water in the gasholder tank. Two methods of arresting the movements for recharging with carbide are described.—J. A. B.

*Acetylene, Impts. in Apparatus for the Production of.* E. Jimeno, Barcelona, Spain. Eng. Pat. 14,090, June 9, 1897.

A WATER vessel is placed above a vessel about double its capacity containing carbide. A capillary communication permits water to flow to the carbide and generate acetylene. Various methods of regulating the pressure on the escape orifice, of automatically closing the communication, and of governing the pressure at the burners, are claimed.—J. A. B.

*Acetylene Gas, Improved Apparatus for the Production and Storage of.* R. F. Carter, Niagara Falls, Canada. Eng. Pat. 17,148, July 21, 1897.

Water is supplied through a ball-cock valve to a large cistern pivoted within a larger tank, in such a manner that the inner cistern tips automatically when the gasholder falls, and discharges a limited volume of water into the outer tank, whence it flows on to carbide in a generator; and the acetylene evolved, raises the gasholder and restores the inner cistern to its original position. Twenty claims are made.—J. A. B.

*Acetylene Gas, Impts. in Apparatus for the Production of.* A. Rieffel, Paris. Eng. Pat. 17,938, July 30, 1897.

THE bell of a gasholder is, by one or other of several specified devices, increased in weight as it rises, and thereby the pressure of gas in the generator varies with the rise and fall of the bell. Water is supplied to the generator under a constant head, which is such that it flows thereto when the pressure therein is low and ceases to flow when it is high. Thus the generation of gas only occurs when the gasholder is nearly empty. Several modifications of various parts are claimed.—J. A. B.

*Acetylene Gas, Improved Apparatus for the Production and Storage of.* H. J. Bell and Niagara Falls Acetylene Gas Machine Company, Ltd, both of Niagara Falls, Canada. Eng. Pat. 19,411, Aug. 23, 1897.

ATTACHED to the side of the bell of a gasholder by a rod is a float which sinks into a water chamber when the bell descends, and expels water from the chamber into a spout surrounded by a sleeve which may be tilted, and is thus caused automatically to discharge its contents into a tip tank, which empties itself into a tank, whence a pipe conveys the water to carbide in a generator. The water chamber is refilled automatically when the bell rises. The generator used is that protected under Eng. Pat. 2284 of 1897 (this Journal, 1897, 431). Fifteen claims are made.—J. A. B.

*Acetylene Gas, An Improved Device for Producing and Burning.* J. Windmüller, Cologne. Eng. Pat. 21,461, Sept. 18, 1897.

THE lower part of a large tube is partially occupied by a smaller tube, which leaves an annular space. This space and the upper part of the apparatus are filled with water, which percolates through a hole near the base to meet the carbide compound in the inner tube, and develops gas, which passes through a hollow rubber ball for regulating the gas pressure, to the lamp, in which an air chamber is provided between the casing and the disc, the burner being so adjusted that it only partially reaches or dips into the casing.—J. A. B.

*Acetylene Gas, Impts. relating to the Production of, and to Lamps for Generating and Burning the same.* H. H. Lake, London. From Wizard Manufacturing Company, Chicago, U.S.A. Eng. Pat. 21,831, Sept. 23, 1897.

REFERS particularly to lamps for bicycles, &c. A stick of carbide is pressed against an absorbent pad, to the under side of which water is admitted from the surrounding water receptacle through a passage, of which the size is fixed by a stem valve. The gas passes through a similar passage to a lava burner tip provided with an air passage. The burner is in a suitable combustion chamber.—J. A. B.

*Blow Torch Burners, Impts. in.* J. C. Dupee, Chicago, U.S.A. Eng. Pat. 18,830, Aug. 14, 1897.

THESE burners, intended for the use of plumbers, braziers, &c., are designed for burning hydrocarbon oils of low specific gravity, as kerosene or crude petroleum. Each burner has an oil reservoir, and an air pump for producing pressure in the reservoir, whereby the oil is forced upwards to an annular retort, wherein it is vaporised, and from which the vapour passes to a nozzle having a needle valve. From the nozzle it passes to the cavity within the retort, where it mixes freely with air, and burns in a combustion chamber fixed thereon. This combustion chamber is arranged so as to cause eddies, by forming it of a pear shape, having a restricted opening at its outer end, an enlargement in the body thereof, and a series of openings in its walls. By this arrangement a portion of the main flame is reversed and forced back through the openings on to the retort, the main flame passing upwards or outwards to heat the brazier's or plumber's pot.—R. S.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Petroleum, Origin of: Spontaneous Polymerisation of Hydrocarbons.* C. Engler. Ber. 30, 2358—2365.

REFERRING to Sadtler's preparation of hydrocarbon gases from vegetable oils (this Journal, 1897, 727), the author points out that similar results have been previously obtained by him (Ber. 21, 1816; 22, 592) from pure stearic and oleic acids. Moreover, that in attributing an animal origin to petroleum deposits in general, he does not imply the impossibility of other methods of formation in isolated cases.

The presence of heavy lubricating oils in natural petroleum has been considered to militate against the theory of animal origin, because the products of the distillation of fat

under pressure consist largely of light ethylenes. However, recent experiments made by the author or under his direction, tend to show that a spontaneous polymerisation of the hydrocarbons occurs in petroleum distillate, coal-tar distillate, &c., which probably explains the development of the heavy oils from the "protopetroleum" first resulting from the distillation of mineral matter, &c.

For example, a distillate from a high-boiling Java petroleum was found to have a sp. gr. averaging 0.8799, which, however increased on standing for some time, to 0.8917. In a second sample from Java, the sp. gr. rose in a few days from 0.8912 to 0.9008. That other petroleum also exhibit the same tendency, though in different degree, was shown by a distillate (b. pt. 300—320 °C.) from Galician residuum, the sp. gr. increasing in one case from 0.8601 to 0.8612, and in another—after heating the residuum for three days under a reflux condenser and then distilling at 320° C.—from 0.8334 to 0.8349 (in 20 days).

A similar behaviour was noticed by Spilker in coal-tar distillates, crude benzene giving an increase of 0.001 in 20 days, and the so-called light oil an increase of 0.00173 in eight weeks. Also in brown-coal-tar distillates an analogous behaviour was discovered by W. Eisenlohr, though here the increase in sp. gr. during the period occupied by the experiments (30 days) was very slight. On the other hand, samples of the fish-oil distillate prepared for the author by Krey, in 1888, and which had an initial sp. gr. of 0.8105, now exhibit, after nine years' storage, densities varying from 0.8221 to 0.8295; and an increase of 0.002 was found to ensue in 30 days in the case of a sample newly distilled from fish oil.

From these samples the author considers it permissible to suppose that the heavy oils in petroleum have gradually been elaborated by spontaneous polymerisation, from the lighter hydrocarbons first formed by distillation; such polymerisation being probably feasible, though at an exceedingly slow rate, at low temperatures. It may be that the change in question is in turn succeeded by intramolecular transpositions. The prevalent temperature and pressure would influence the character of the resulting products, and determine the preponderance of saturated, unsaturated, open-chain, or cyclic hydrocarbons, and may thus account for the differences in composition exhibited by natural petroleum.—C. S.

*Petroleum, Japanese.* Eng. and Mining J. 1897, 64, [11], 394.

THE oil districts of Japan extend from Hokkaido to Akita in the north, traverse the provinces of Echigo and Shinano, and reach the Totomi Province. Previous to the year 1890, wells were sunk in an unscientific manner to a depth of about 600 ft., but since that time American boring machinery has been introduced, and oil is now being obtained from a depth of 800 to 2,000 ft. The method of refining has also been improved to such an extent that Japanese petroleum is at present equal in quality to foreign petroleum.—A. S.

*Petroleum in Texas.* Eng. and Mining J. 1897, 64, [14], 398.

THERE has been discovered at Corsicana, Texas, at a depth of 1,040 ft., a seam of bluish sandy shale, about 20 ft. thick, saturated with petroleum. The stratum above and below this stratum consists of a hard clay. The oil was found, on analysis, to contain about 90 per cent. of volatile matter. In the following table, the Texas petroleum is compared with the oils from other districts:—

Crude oil from	Specific Gravity at 17° C.	Began to boil at	Came over below 150° C.	Between 150° and 360° C.	Above 360° C.
		° C.	Per Cent.	Per Cent.	Per Cent.
Texas-Corsicana	0.821	80	34.6	40	15.8
Pennsylvania	0.818	82	21.0	38	40.7
Galicia	0.824	90	26.5	47	26.5
Baku	0.859	91	23.0	38	39.0
Alsace	0.907	135	3.0	50	47.0
Hanover	0.899	170	..	32	68.0

—A. S.

*Petroleum: Is the Occurrence of Nitrogen in, an Unassailable Proof of Organic Origin?* K. W. Charit-schikoff. Chem. Rev. Fort. u. Hartz Ind. 4, 21, 289—290.

THE author—who supports (J. Russ. Phys. Chem. Ges. 29, 151) the inorganic theory of origin—considers that the presence of nitrogen compounds in petroleum is capable of explanation without resorting to an organic theory of origin, since modern research is continually affording instances of the direct combination of nitrogen with various substances, particularly in processes of combustion occurring in presence of this element. He believes the formation of petroleum to be effected at depths not very remote from the earth's surface, and that, under such circumstances it is not impossible for the nitrogen compounds to have resulted from subsidiary reactions going on in presence of nitrogen either in a free state or dissolved in sea water. The accuracy of this view will, he believes, be confirmed as future research enlarges our knowledge of the chemistry of nitrogen.—C. S.

*Petroleum, Refining, with Fuming Sulphuric Acid.* Fr. Boleg. Chem. Rev. Fort. u. Hartz Ind. 4, [19], 263.

THE author states that the process patented by the Badische Anilin und Soda Fabrik (this Journal, 1897, 504) has been—in principle—employed by him during the past ten years, and consequently cannot be regarded as novel, though the apparatus is new. The same results can, however, be obtained by using an ordinary lead-lined, steam-blast agitator, but working it with compressed air and leading the acid into the air-pipe, which is fitted with an atomising jet.—C. S.

*Mineral Oil, Refining with Water-Glass.* J. R. Miehler. Chem. Zeit. 21, [82], 853.

AS a means of preventing the formation of the troublesome emulsions occurring in the alkali treatment of heavy mineral oil distillates, the author recommends the employment of alkali silicate (water-glass), either alone or in conjunction with sodium carbonate or caustic soda, for neutralising the oil after the acid treatment. The advantages claimed for this reagent are that a smaller quantity of acid is needed, since the dark oil then obtained is bleached by the action of the precipitated silica, and that this body at the same time disperses any emulsion produced in the oil.—C. S.

*Petroleum Spirit [Benzine] from Grosni Petroleum, Sulphur Compounds in.* K. W. Charit-schikow. Trudy bak. otd. imp. russk. techn. obschtsch. 1897, 12, 272; through Chem. Zeit. Rep. 1897, 26, [74], 203.

THE fraction of the Grosni petroleum boiling up to 150 °C. is in many external characteristics similar to Ohio petroleum, and has a disagreeable smell, which is not removed by purification with the usual reagents. The author has therefore examined the sulphur compounds present, in the belief that they gave rise to the odour in question. To determine the presence of these compounds, the benzine was treated with a 5 per cent. solution of corrosive sublimate, or with weak platinum chloride solution, after removing a trace of hydrogen sulphide by means of lead acetate. The substances obtained after the sublimate treatment reacted like mercaptans, but contained not more than 7—10 per cent. of sulphur. Further research showed that some hydrocarbons (of the acetylene series) as well as the sulphur compounds, entered into combination with the mercuric chloride. For the determination of sulphur in fractions containing but little of this substance, both Hensler's method and Engler's modification of it proved to be ill-adapted: too much of the distillate had to be burned. The author only determined the sulphur in the compounds separated by means of mercuric chloride, and then used the Hensler-Engler method to prove qualitatively that the whole of the sulphur had been removed by the mercuric salt. The sulphur found in the benzines examined, varied between 0.003 and 0.019 per cent. No regularity could be traced in the distribution of the sulphur compounds between the fractions of different boiling point; all that may be safely stated is that sulphur compounds are always present in the petroleum

spirit (sp. gr. 0.685), whilst the naphtha (ligroin) distillates (sp. gr. 0.73 to 0.77) appear to be free from sulphur.

—W. G. M.

*Olefines, Naphthenes, and Benzene Hydrocarbons; Formation of, by the Distillation of Fats under Pressure.* C. Engler and Th. Lehmann. Ber. 30, [15], 2365—2368.

By treating the various fractions of fish-oil distillate by the bromination method, the purified bromides were found to correspond to hexylene bromide in the fraction 50°—60° C., whilst in the fraction 70°—80° C. they approximated to heptylene bromide. The remaining fractions were apparently mixtures of higher and lower homologous olefine bromides.

The detection of naphthenes was attempted by examining the composition of various fractions after the removal of the olefines, aromatic hydrocarbons, &c., with the result that, whilst the fractions 68.5°—69.5°, 78°—80°, 98°—99°, 123°—124°, 149.5°—150.5°, and 160°—162° C. appeared to consist mainly of paraffins, the presence of naphthenes was also indicated. The quantities of substance employed were, however, too small to permit of the isolation of these hydrocarbons.

Benzene hydrocarbons were detected without difficulty by nitration, *viz.*, benzene in the fraction 76°—83° C., toluene in the fraction 106°—111°, *m*-xylene in that between 130° and 138°, and mesitylene and pseudocumene in the fraction 160°—169° C.

Pure glycerides and other fats and oils gave, on the whole, analogous results.—C. S.

#### IV.—COLOURING MATTERS AND DYES.

*Aposafraanine, Action of Bases on.* O. Fischer and C. Giesen. Ber. 30, 2489—2494.

In continuation of Fischer and Hepp's work on the formation of Induline and Fluorindine from Aposafraanine (Ber. 29, 361; this Journal, 1896, 536), the authors have investigated the action of methylamine, *p*-anisidine, ethylene diamine, *o*-amidophenol, and *o*-naphthylene diamine on Aposafraanine. They find that the monamines form Indulines, whilst the diamines yield Fluorindines in addition. Methylamino-aposafraanine is obtained by heating together in a sealed tube to 100° C. for 5—6 hours, 4 grms. of Aposafraanine hydrochloride, 2 grms. of methylamine hydrochloride, 10 c.c. of a 33 per cent. methylamine solution, and 40—50 grms. of alcohol. The solution is filtered, acidulated, evaporated, the residue extracted with water, and salted out, preferably with potassium bromide. The bromide of the induline crystallises from water or dilute alcohol in brownish needles. The solution in water is orange-red, which is turned magenta-red by concentrated hydrochloric acid. An analogous compound is formed by boiling together 5 grms. each of Aposafraanine hydrochloride, *p*-anisidine, and *p*-anisidine hydrochloride in 100 grms. of alcohol. The product crystallises in greenish crystals, which dissolve to a brown solution. By the action of ethylene diamine on Aposafraanine, two different substances are formed, one of which shows the reactions of an induline, whilst the other belongs to the class of the fluorindines and can be obtained by oxidation of the former. The Induline is formed by heating 5 grms. each of Aposafraanine hydrochloride, ethylene diamine, and ethylene diamine hydrochloride with 80 grms. of alcohol under an inverted condenser for two hours. The solution is then made alkaline with potash and precipitated with water. The brown powder so obtained, after crystallisation from dilute alcohol, forms acicular crystals with a bluish-green reflex. The base dissolves to an orange-red non-fluorescent solution, which is turned violet by dilute mineral acids. The hydrochloride dissolves in hot water and in alcohol to a yellowish-red solution, and is a strong dyestuff. The base melts with decomposition, being partially converted into the fluorescent compound. This conversion is easily effected by oxidising agents, especially by mercuric oxide in nitrobenzene solution. The fluorindine can also be obtained directly by heating the original melt to 150—160° C. for some hours. The shining greenish crystalline product so obtained, only dissolves with difficulty in the usual solvents; the yellow

solutions in benzene, xylene, &c., have a greenish-yellow fluorescence. Two possible formulæ are given. By heating equimolecular proportions of Aposafraanine hydrochloride, *o*-amidophenol hydrochloride, and *o*-amidophenol in an alcoholic solution under an inverted condenser for about 12 hours, the magenta solution gradually turns blue. The boiling solution is then treated with alcoholic ammonia and the brown base recrystallised from benzoic ethyl ether. The product forms brownish-red needles, which dissolve in alcohol to a cherry red, in benzene and toluene to yellowish-red solutions, which have a blood-red fluorescence. Apparently a product is formed which is at the same time an oxazine and an azine, and hence stands intermediate between triphenioxazine and phenylfluorindine—

A similar substance is obtained by the action of *o*-naphthylene diamine hydrochloride on Aposafraanine in an alcoholic solution. The substance is very sparingly soluble; the alcoholic solution is red with a blood-red fluorescence; on acidifying, the solution turns blue and the fluorescence greenish.—T. A. L.

*Rosindone and Aposafraanine, Action of Phosphoric Chloride on.* O. Fischer and E. Hepp. Ber. 30, 1827—1831.

When one molecular proportion of rosindone is dissolved in five times its weight of phosphorus oxychloride and one molecular proportion of phosphorus pentachloride is added, a reaction occurs spontaneously. After distilling off the oxychloride, the yellow residue is washed with ether, and when recrystallised from alcohol, yields reddish-yellow shining metallic plates. The substance has the formula C<sub>20</sub>H<sub>11</sub>N<sub>3</sub>Cl<sub>3</sub>, is easily soluble in water, tolerably easily in alcohol, with a faint greenish fluorescence, but insoluble in ether or petroleum ether. It can be precipitated from its aqueous solution by salt, and it dissolves in concentrated sulphuric acid to a cherry-red solution, which is not decolorised. On dilution this solution turns yellow. The substance is unstable to alkalis, and is reconverted on standing with dilute caustic soda lye or sodium carbonate, or on boiling with sodium acetate, into rosindone. It reacts with potassium bromide, iodide, or nitrate, forming the corresponding salt, and it probably has the following constitution:—

that is to say, is chloronaphthophenazonium chloride, and the authors suggest that a similar transformation takes place here to that in the case of the diazotisation of the green rosinduline salts according to Kehrman, which yields naphthophenazonium derivatives. They admit that this reaction of rosindone points rather to the anhydride than to the *p*-quinone formula of rosindone, although, of course, a transformation may have been effected by means of the phosphoric chloride. The salts of chloronaphthophenazonium readily react with bases. Thus, on dissolving the hydrochloride in an alcoholic solution, together with an excess of aniline, and warming slightly, phenylrosinduline

can be obtained from the melt after driving off the aniline with steam. It is formed quantitatively, and melts at  $236^{\circ}\text{C}$ . In a similar manner methyl rosinduline can be obtained by the action of methylamine, and crystallises from a mixture of benzene and petroleum spirit in greenish prisms melting at  $181^{\circ}\text{C}$ . On replacing the methylamine by ethylamine, ethylrosinduline is produced, which is identical with that previously obtained from benzene-azo- $\alpha$ -ethylnaphthylamine (Annalen, 256, 237). It crystallises from dilute alcohol in greenish needles melting at  $184^{\circ}\text{C}$ . (see also this Journal, 1889, 877).

The action of phosphorus pentachloride on Aposafrazone yields a product analogous to that obtained from rosindone. Finely powdered Aposafrazone is dissolved in phosphorus oxychloride in the cold, and one molecular proportion of phosphorus pentachloride is carefully added. After standing about an hour with occasional agitation, a current of air is passed through the greenish-yellow solution at  $40$ – $50^{\circ}\text{C}$ , to remove the phosphorus oxychloride. The residue is then taken up with water, and, after filtering and concentrating, the chlorophenylphenazonium chloride—

is salted out. Like the rosindone derivative, it reacts with aniline, and is converted by digestion with the base in an alcoholic solution into phenylaposafranine,  $\text{C}_{20}\text{H}_{17}\text{N}_3$ , which melts at  $201^{\circ}\text{C}$ . and gives a characteristic nitrate.

—T. A. L.

#### Azo Dyestuffs, The After-treatment of, with Copper Salts.

C. Kumpf. Färber-Zeit. 8, [19], 293.

As is now well known, dyestuffs which contain dianisidine as a component (such as benzo-azurine) can be made faster to light on the fibre, and, in a lesser degree, also to soap, by treating the dyed material with copper salts. The colour, however, is changed at the same time from a pure blue to a greenish shade. The author has treated with copper salts benzopurpurine 10 B, which also contains dianisidine, and obtained a reddish-blue. The fastness to soap was thereby increased, but not the fastness to light. From this and other like experiments with other dyestuffs, all of which gave varying results, the author concludes that the other components of the dyestuffs—besides the dianisidine—must have a share in the reaction when treated with copper salts.—I. S.

#### Bixin. K. G. Zwick. Ber. 30, 1972.

The author describes a method by which he has separated Bixin, the colouring principle of Annatto, in a crystalline form. Well-dried Annatto is ground to a fine powder, moistened with chloroform, and extracted for 24 hours. After distilling off the chloroform, the residue is dried on a water-bath, ground, and extracted in a Soxhlet with petroleum ether of low boiling point. The undissolved residue, after drying, is again extracted with chloroform until the extract is colourless. The crystals which separate from the chloroform are, after drying, washed with petroleum ether, again extracted with chloroform, and separated by fractional crystallisation. They are then washed with a little chloroform, and dried, first in the air, and finally on a water-bath, and correspond in crystalline form and composition with those obtained by Ettli.—T. A. L.

#### Maclurin, Dyeing Properties of. L. Schnell. Mitth. k. k. Techn. Gew. Museums in Wien, 1897, 7, 171–172.

Two preparations of the compound were employed in the experiments: one, a pale yellow, crystalline powder, which was recrystallised from water; the other, the isolation of which had been effected by Herzig, an almost white product. They were found to behave similarly.

Maclurin dyes iron-mordanted cotton faint brownish-grey, alumina-mordanted cotton pale brownish-yellow, while it produces scarcely any change upon the same fibre when mordanted with chrome. The colours of the lakes produced are exceedingly pale.

To show that the dyeings are not due to the presence of traces of Morin in the samples, a portion of one of them was fractionally precipitated from aqueous solution by lead acetate. The various portions of the compound liberated from the several fractions, in dyeing, behaved alike.

Maclurin exhibits close analogies with the pyrogallol tannins: thus, it is precipitated by tannic acid and albumin, and is partially, if not completely, absorbed from aqueous solution by hide powder, besides having dyeing properties similar to that class of compounds.

Clamianin has obtained by the action of sodium acetate and acetic anhydride on Maclurin, a coumarin compound of the formula—

This theoretically should possess greater colouring power than Maclurin. It does not, however. But its dibromo derivative is a dyestuff of some value.—E. B.

#### PATENTS.

Sulpho Acids, and Colouring Matters [Browns, Blacks] therefrom: Impts. in the Production of. Read Holliday, Sons, and Co., Ltd., J. Turner, and H. Dean, Huddersfield. Eng. Pat. 26,020, Nov. 18, 1896.

By reducing the 1,2', 1,3', or 1,4'-nitronaphthylamines with normal or acid sulphites soluble in water, they are converted into sulphonic acids of the corresponding naphthylene diamines, which yield tetrazo compounds capable of combination to form dye-stuffs. 100 kilos. of 1,3'-nitronaphthylamine are boiled with 700 kilos. of concentrated sodium bisulphite until dissolved. The solution is acidified with hydrochloric acid, and boiled until all the sulphurous acid is expelled, when 1,3'-naphthylene diamine sulphonic acid crystallises out on cooling as a sandy, green precipitate. To obtain a brown dyestuff, 34 kilos. of the sulphonic acid are converted into the tetrazo compound and added to 36 kilos. of  $\alpha$ -naphthylamine hydrochloride in solution. After filtering off the dyestuff, it is converted into the sodium salt, which dyes brown shades on vegetable fibres, and may be diazotised and developed thereon, yielding shades of considerable intensity. According to another process the patentees proceed as follows: 21.2 kilos. of tolidine are converted into the tetrazo compound, and run into a solution containing 68 kilos. of 1,2'-naphthylene diamine sulphonic acid made alkaline with soda. The dyestuff thus produced, gives brown shades on unmoordanted cotton, and may be further diazotised and developed on the fibre. For the production of a black dye-stuff, 18.4 kilos. of benzidine are converted into the tetrazo compound and added to a solution containing 34 kilos. of 1,2'-naphthylene diamine sulphonic acid containing just sufficient soda to neutralise the free acid. The intermediate product formed, is then run into a solution of 24 kilos. of amidonaphthol sulphonic acid G, dissolved in soda. After standing a few hours, the dyestuff is filtered off, pressed, and dried. It gives violet-black shades on vegetable fibres, which, after rediazotising and developing, yield deep ingrain blacks.

—T. A. L.

Basic Disazo Dyestuffs [Reds], Manufacture of. O. Imray, London. From "Die Farbwerke vorm. Meister, Lucien, and Brüning," Hoechst a. M., Germany. Eng. Pat. 27,896, Dec. 7, 1896.

The patentees find that disazo dyestuffs containing an aromatic amido ammonium base possess the important property of dyeing wool and cotton simultaneously from an acid bath. Such dyestuffs have been obtained by diazotising aromatic amido ammonium bases, and combining them with other components. Dyestuffs having similar properties may also be obtained by diazotising amido-azo compounds, and combining them with aromatic oxy-ammonium bases, such for instance as 2,2'-oxy-naphthylene trimethyl ammonium. The diazo compound from 23.3 kilos. of amido-azobenzene hydrochloride, 18 kilos. of hydrochloric acid ( $20^{\circ}\text{B}$ ), and 7 kilos. of sodium nitrite, after adding 22 kilos. of crystallised sodium acetate, is run

into a solution containing 24 kilos. of 2,2'-naphthol trimethylammonium chloride. The dyestuff is salted out and purified by re-dissolving. It forms red flakes, and dyes wool and cotton cherry red from an acid bath.—T. A. L.

*Dyestuffs of the Series known as "Patent Blue," Manufacturers of.* O. Murray, London. From "The Farbwerke vorm. Meister, Lucius, and Brüning," Hoechst a.M., Germany. Eng. Pat. 29,706, Dec. 24, 1896.

THE properties of dyeing evenly and of fastness possessed by dyestuffs of the Patent Blue series, depend upon the ortho position of a sulphonic acid group, relatively to the methane carbon, and the following reactions are characteristic for these sulphonic acids. (1.) If a weak mineral acid solution of the leuco compound be boiled with ferric chloride, a bluish-green solution is formed, which, on saturation with ammonia, gives an intensely blue filtrate. (2.) The Patent Blue dyestuffs on boiling with caustic soda lye, split off alkylamine and form violet to yellowish-red solutions of phenol dyestuffs. The dyestuffs hitherto known, belong to the diamidotriphenylmethane series. In the present specification, dyestuffs of this group are described which are derivatives of triamidodiphenyl-*o*-tolylmethane.—

They may be obtained by condensing alkylated diamidotriphenyl carbinols with the sulphonic acids of monoalkylated *o*-toluidine and oxidation of the leucosulphonic acids thus produced. If benzyl-*o*-toluidine be employed, it is to be noted that the first sulphonic acid enters the tolyl residue, and this acid is produced if the solution of the base in sulphuric acid monohydrate be mixed with fuming sulphuric acid. The disulphonic acid (the second sulphonic group being in the benzyl residue) is formed when the base is dissolved in fuming sulphuric acid. The condensation is carried out as follows:—27 kilos. of tetramethyl-diamido diphenylcarbinol are dissolved in 35 kilos. of hydrochloric acid (30 per cent.) and 100 litres of water, and mixed with 40 kilos. of the calcium salt of benzyl-*o*-toluidine disulphonic acid in 50 litres of water. The whole is heated for 10–12 hours on the water-bath until a sample is completely soluble in ammonia, indicating the disappearance of the carbinol. The solution is then treated with sodium carbonate until it has an alkaline reaction, filtered from calcium carbonate, and the leuco salt is salted out from the filtrate and dried. In order to oxidise it, 10 kilos. of the above salt are dissolved in 300 litres of water, the solution is heated to 60°–70° C., mixed with the calculated quantity of lead peroxide and acetic acid, and 6 kilos. of sodium sulphate are subsequently added to precipitate the lead. The dyestuff is salted out from the filtrate, or this latter is evaporated *in vacuo*. The new product forms copper-coloured crystals easily soluble in water to a blue solution, which is dichroic, being bluish-red by transmitted, and bluish-green by reflected light. The solution is unaltered by ammonia or sodium carbonate, but turns violet when boiled with caustic soda lye. The dyestuff gives blue shades with a green reflex on wool and silk from an acid bath. The shades do not appear redder in artificial light.—T. A. L.

*Brown Colouring Matter [from Dinitroresol], Production of.* S. Pitt, Sutton. From L. Cassella and Co., Frankfurt-on-Main, Germany. Eng. Pat. 29,828, Dec. 28, 1896.

WHEN dinitroresol is heated with sulphur and an alkaline sulphide, it yields a melt containing a dyestuff of unknown constitution, which gives brown shades on unimordanted cotton in presence of sulphides or strong alkalis. The following quantities are given:—25 kilos. of dinitroresol are heated with 125 kilos. of sodium sulphide and 50 kilos. of sulphur for 1 hour to 100° C. The temperature is then gradually raised to 160° C., and maintained thereat until the melt has become solid, which takes about 2–3 hours. The melt, after having been broken up, can be used directly,

or its solution may be carefully mixed with hydrochloric acid until the reaction is neutral. The precipitated dyestuff is filtered off and made into a paste or dried, but in this case it must be dissolved in soda lye or sodium sulphide before dyeing.—T. A. L.

*Inks [Fugitive Plate], for Use in Printing from Engraved Plates, Impts. in.* R. Webb, London. Eng. Pat. 26,992, Nov. 27, 1896.

1 DRAM. of sodium carbonate and 2 or 3 drms. of yellow soap are dissolved by boiling with 10 oz. of water, and the solution is well stirred into 4 oz. of a mixture of four parts of flour and one part of magnesia, the whole being tinted to shade with a soluble dye. In cold or damp weather a little dextrin may be added to assist the drying. When used on a "security" paper containing a sensitive substance the colour of which it is liable to change, some alkaline carbonate (preferably the ammonium salt) should be incorporated with the ink to prevent this action. The completed material forms a "security" or "Docteur" plate ink for printing from engraved (*i.e.*, intaglio) plates; and it is principally employed in the production of bankers' cheques, &c., to prevent fraud. [See also Eng. Pat. 19,783, below.]

—F. H. L.

*Printing Inks, Impts. in the Method or Process of Making.* D. J. Ogilvy, Cincinnati, U.S.A. Eng. Pat. 18,533, Aug. 10, 1897.

THE essential feature of this patent consists in the statement that the pigment and vehicle of a (black) printers' ink can be effectually mixed together by agitation with high-pressure or superheated steam, so that the varnish is prepared, deodorised, and the ink finished all in one operation. The oil (rosin, petroleum, shale, linseed, &c.), the solid rosin, and the pigment (lampblack or carbon black) are placed in a closed vessel connected with a condenser, and the steam is turned on "until the result is satisfactory." "When sufficiently treated, the product is passed, if desired, through a straining or grinding apparatus . . ." The proportions of the several ingredients depend partly on the weather and the class of trade for which the ink is intended, and partly on the amount of volatile matter driven off by the steam.

—F. H. L.

*Printing Inks [Fugitive Letterpress], Impts. in.* R. Webb, London. Eng. Pat. 19,783, Aug. 27, 1897.

EIGHTY-THREE parts of dextrin are mechanically mixed with 17 of treacle or golden syrup, 50 parts of glycerin added, and then sufficient aniline colouring matter to give the desired tint. The proportions vary somewhat, according to the state of the weather, and in summer it may be necessary to use a little phenol or salicylic acid as an antiseptic. The finished material forms a "fugitive" or "security" letterpress ink [for printing from type or relief].—F. H. L.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Yarns, Enamelled.* C. D. Rice, jun. Textile Colorist, 1897, 19, 289–290.

ENAMELLED yarns are a device for producing various effects in woven designs. The yarn is impregnated with a hot paste, consisting of flour, tallow, grease, &c., with or without colouring matter; and, when cool, is passed between rollers to distribute the paste evenly. When dry, the yarn receives two or three successive coatings of a varnish or "enamel." "Flake effects" are produced by applying ground mica while the enamel is yet moist.—I. S.

*Fatty Acids, Volatile; Production of, from Wool Washings.* A. and P. Baisine. Comptes Rend. 1897, 125, [20], 777–780.

WHEN wool washings are allowed to stand, a spontaneous fermentation takes place, in which the volatile fatty acids, from acetic to caproic, are produced. It is suggested that these washings might serve as an abundant source of these acids, some of which are rare and difficult to procure. The

washings give the largest yield in volatile acids after a week's fermentation. The following table gives their composition at this period:—

Density .....	1.079
Dry residue .....	153.4 grms. per litre.
Ammonia (as carbonate) .....	1.5 .. ..
Total nitrogen .....	1.5 .. ..
Carbonate of potash (ready formed) ..	7.6 .. ..
Volatile acids (expressed as $H_2SO_4$ ) ..	16.0 .. ..
Fatty matter .....	15.5 .. ..
Mineral matter .....	77.4 .. ..
Total carbonate of potash .....	60.5 .. ..

The fermented liquid is boiled to drive off ammonia, then acidified, and the volatile acids distilled off in a current of steam. The higher acids pass over first; the longer the distillation is continued the more acetic acid is obtained. The residual solution, on concentration, deposits potassium sulphate, and the calcined residue is rich in carbonate of potash. If carbonate of lime be added before calcination, all the potash is obtained as carbonate. The nitrogenous matters give ammonia, which may be collected.

The distillate contains the fatty acids in the following proportions:—

	Per Cent. of the Mixture.	Per Litre of Washings. Grams.
Formic acid .....	Traces	Traces
Acetic " .....	60	10.7
Propionic " .....	25	5.4
Butyric " .....	5	1.3
Valeric " .....	1	1.2
Caproic " .....	3	1.0
Caprylic " .....	Traces	Traces
Benzonic " .....	3	1.0
Phenol .....	Traces	Traces

The washings of different wools vary little in composition, or in the yield of acids obtained. The crude mixture of acids is suitable for the preparation of acetone, methyl ethyl ketone, and the acetone oil used for the denaturing of alcohol. By the addition of the proper amount of carbonate of lime, followed by steam distillation, pure acetate of lime is obtained, the other acids coming over with the water.

The wool washings of Roubaix and Tourcoing amount to 500 cb. m. per day. By treatment of these, 10 kilos. of acetic acid, 5–6 kilos. of propionic acid, and 20 kilos. of ammonium sulphate might be obtained per cb. m. in addition to the carbonate of potash now produced.

—A. C. W.

*Textiles, Soaps for.* Leipziger Färber- u. Zeugdr. Zeit. 46, [11], 491.

See under XII., page 1023.

## PATENTS.

*Textile Fabrics, Impts. relating to the Manufacture of.* V. Bona, Carignano, Turin, Italy. Eng. Pat. 25,362, Nov. 11, 1896.

This invention relates to the use of the outer waste silk of the cocoons, silk-floss or "spelaia," as it is called, in the manufacture of mixed woollen goods. The material is ungummed, dried, carded, and combed. It is then mixed with shoddy or wool in the desired proportion, and treated as usual. The addition of 15 per cent. of floss-silk greatly increases the tensile strength and fineness of the thread that can be obtained from shoddy or wool, and a material improvement in the goods is effected.—H. I.

*Silk like Gloss Effects on Cotton or Linen Stuffs by means of Printing, Production of Local Durable.* O. Imray, London. From The Farbwerke vormals Meister, Lucius, and Brüning, Höchst a Main, Germany. Eng. Pat. 29,832, Dec. 28, 1896.

THESE are produced by the local mercerising of the fabric by caustic soda, according to a modification of the process of

Thomas and Prevost. The material is printed with a composition containing, for example, 70 pts. of British gum and 930 pts. of soda lye of 10° B, with or without the addition of dyestuffs or mordants. It is then washed in "a stretched state until the inner tension of the fibre has ceased." For resist styles the fibre is printed with substances, such as albumin, casein, various oxides, acids, and salts, which will resist or neutralise the mercerising action of the caustic lye. The fabric is then mercerised and washed under tension as before. By this treatment, a permanent gloss is imparted to the cotton, and the affinity for dyestuffs and mordants is increased. See also Ger. Pat. 83,414 of Thomas and Prevost.—H. I.

*Textile Plants (Ramie, &c.), Impts. in the Treatment of, to remove Fibre therefrom.* C. L. Bachelier, Paris. Eng. Pat. 12,541, May 29, 1897.

A quick method of retting is described in this invention. The freshly-cut plants (Ramie) are introduced, on trellis-work supports, into a large gas-tight chamber, and subjected for some minutes to the action of gaseous carbonic acid under a pressure of about two atmospheres. After removing the pressure, the plants are removed and dried. They are then passed through breaking rollers, when the plant gum is said to fall off and leave the fibre clean, supple, and brilliant, ready for the combing operation. By introducing sulphurous acid or chlorine into the gas, bleaching may be effected as the retting progresses.—H. I.

*Nitrocellulose, Impts. in Treating, for the purpose of Coating or Impregnating Textile and other Fabrics.* D. M. Sutherland, Sunbury-on-Thames, and W. McLaren, London. Eng. Pat. 28,613, Sept. 14, 1897.

This invention relates partly to solutions of nitrocellulose and analogous substances, such as parkesine, ivorine, xylonite, and celluloid, and partly to the methods of applying such substances to the purpose of coating textile fabrics. In one method of producing the solvent, pyroigneous acid is first prepared, by distilling off the spirit from crude acetic acid obtained by the destructive distillation of wood. The spirit is redistilled three times, the last two distillations being conducted in copper stills heated by steam coils, taking care that the temperature does not exceed 180° F. For the last distillation, from 1 to 1½ per cent. by weight of sodium carbonate is added, in order to neutralise any free acid that may remain; the acid in the distillate existing in the form of methyl and dimethyl acetate. The mixture used by the patentees is of a strength of about 42° overproof at 50° F. It is free from acidity, and rich in methyl alcohol and methyl acetate.

In preparing a suitable solution, nitrocellulose is then agitated with the spirit in suitable closed vessels, and with the addition of castor oils and gums.

The solution may be used for coating textile fabrics or for coating paper, plain or printed, felt, leather-cloth, oil-cloth, linoleum, and all other materials in web form having a fairly even surface, by using well-known spreading machines. After drying, suitable designs are stamped on the material.

—D. B.

*Fibres, Vegetable, for Textile Purposes; Improved Process and Apparatus for Preparing.* J. S. Brown, Bally, Bengal, India. Eng. Pat. 26,185, Nov. 23, 1897.

THE stems of plants of the urtica or nettle family are placed in a cage and boiled for 1–1½ hours in a caustic alkaline solution, to which a proportion of kerosene oil has been added. After cooling and washing, the stems are fed into a straightening machine. This consists of a large, pegged drum into which 10 smaller pin-rollers work, removing from the large drum such stems as lie transversely and obliquely to the direction of motion. These stems are returned to the drum so that they lie parallel to the others. From the straightening machine, they pass between two endless aprons of wire-net, through a washing machine, where the remaining epidermis and gummy matters are removed; the stems are finally dried.—H. I.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Dyeing, The Theory of.* L. Vignon. Comptes Rend. 1897, 125, [6], 357–360.

The author investigates the nature of the dyeing process when cotton is dyed with the substantive or "direct" colouring matters, and seeks to establish which molecular groups confer this property of direct dyeing. He has estimated the amount of various substances, chemically related to the direct dyestuffs, taken up by cotton from boiling solutions. This estimation was effected either by the increase in weight of the well-washed cotton, or by the amount of the substance remaining in the bath after the operation. The following table gives the amount of each substance absorbed, per 100 grms. of cotton, after 15 minutes' boiling. The neutral bath consists of 1 gm. of substance dissolved in 250 c.c. of water; the alkaline bath contains in addition 3.5 grms. of sodium carbonate, 1 gm. of cotton being used in each case. The bases employed in the form of neutral hydrochlorides.

	Neutral Bath.	Alkaline Bath.
Ammonia.....	0.2–0.4	0.2
Hydroxylamine.....	0.0–0.3	0.2
Hydrazine.....	1.2	1.7
Phenylhydrazine.....	3.6	2.9
Diphenyl (dissolved in petroleum spirit).....	0.0	..
Azobenzene (dissolved in petroleum spirit).....	0.0	..
Aniline.....	0.7	0.1
Dimethylaniline.....	0.0	0.0
Diphenylamine.....	0.3	0.4
<i>o</i> -Phenylenediamine.....	0.4	0.6
<i>m</i> -Phenylenediamine.....	0.4	2.4
<i>p</i> -Phenylenediamine.....	0.7	3.2
Benzidine.....	5.7–6.2	5.6
Tetramethylbenzidine.....	7.0	6.3
Benzidine sulphonic acid.....	7.4	4.8
Diamidostilbene disulphonic acid.....	3.5	3.6
Dianisidine.....	6.9	5.7
Diamidomaphthalene.....	0.1	1.7

From these results, conclusions may be drawn as follows:—The fixation of the direct colours is evidently due to chemical combination, and depends upon molecular grouping. This property is not due to the presence of a benzene nucleus, to free nitrogen atoms, or to two nitrogen atoms joined to form the azo group, since diphenyl, ammonia, hydroxylamine, and azobenzene are not absorbed. However, the diamines (except *o*-phenylenediamine) and the hydrazines are absorbed to a considerable extent, and the absorption appears to be independent of the degree of substitution of the azotised molecular groups. Apparently the property of direct dyeing is due to the groupings  $>N-R-N<$  or  $>N=N<$  i.e., to two hydrazinic nitrogen atoms, united either directly or by means of aromatic residues. The two nitrogen atoms may be combined with H, CH<sub>3</sub>, or with other N atoms forming azo groups. These N atoms in the direct colouring matters can unite with the cellulose molecule, and thus become pentatomic—

This theory is supported by the fact that benzidine and tetramethylbenzidine are absorbed by the cotton, while the methyl iodide compound of tetramethylbenzidine, in which the nitrogen atoms are already pentatomic, is not absorbed in the least.—R. B. B.

*Silk, The Dyeing of Artificial.* Leipziger Färber- u. Zeugdr. Zeit. 46, [11], 501.

The author directs attention to the researches of Kuhlmann on the dyeing of pyroxylin, which, though made in 1856, are of interest in connection with the dyeing of artificial silk. It is pointed out that moisture at a high temperature affects the strength of the fibre, and that, therefore, the temperature of the dye-bath should not exceed

60° C. Alkalinity or acidity of the bath should also be avoided, as tending to weaken the strength of the fibre. The most suitable dyestuffs are the basic colouring matters, which are applied in a cold and neutral bath.—I. S.

*Indigo on Cotton Fabrics, Printing with.* C. Kurz. Leipziger Färber- u. Zeugdr. Zeit. 46, [11], 479–480.

The author describes the difficulties of printing with indigo according to the well-known method of Schlieper and Baum, and recommends the following simplified process:—10 grms. of pure indigo are dissolved in 200 c.c. of aniline, by digesting it in the latter at the boil for 15 minutes. The clear solution is decanted and allowed to cool. A finely divided indigo paste is thus obtained, well adapted for the purpose of printing. For thickening purposes the following preparation is used:—In 10 litres of soda lye of 38° B. are dissolved 4,000 grms. of sodium hydrate, to which are then added 10 litres of a dextrin solution, 1:1. To 8 parts of this thickening are added 2 parts of the indigo paste as above described, and the same is then printed on the fabric that has previously been padded in a solution of glucose of 5° B. After printing and drying, steam for two minutes in a Mather and Platt ager, and wash. 40 grms. of indigo per litre of printing colour is a proportion said to be sufficient for very deep shades.—I. S.

*Lactic Acid as a Solvent for Dyestuffs.* Leipziger Färber- u. Zeugdr. Zeit. 46, [11], 486–487.

The use of lactic acid for dissolving dyestuffs which are insoluble in water, has been patented in France. For spirit-soluble Indulines and Indigo, about four times the weight of acid is taken, and the dyestuffs may then be used for printing on cotton or wool.—I. S.

### PATENTS.

*Bleaching Textile Vegetable Fibres, Yarns, and Fabrics; Impts. in.* A. F. B. Gomess. Eng. Eng. Pat. 28,266, Dec. 10, 1896.

The ordinary caustic lye is replaced, according to this patent, by a mixture of caustic soda solution and zinc (dust), in the proportions necessary for the solution of the zinc oxide formed.—H. I.

*Paranitraniline Red, Impts. in the Production of.* A. G. Green, Heaton Moor, Stockport. Eng. Pat. 28,499, Dec. 12, 1896.

The process consists in "mercerising" the cotton fibre before impregnating it with the alkaline  $\beta$ -naphthol solution. The red so obtained is said to possess greater fulness, evenness, brilliancy, and blueness of shade than when dyed by the ordinary process, and it is also claimed to be faster to light. The cotton is immersed in cold caustic soda lye (30 Tw.) for a half to one hour. It is then washed and grounded with  $\beta$ -naphthol, which may be used of half the usual strength, viz., 1 lb. instead of 2 lb. to every 8 galls. of water. The mercerising process can be shortened by employing a stronger caustic lye, such as one from 40–50° Tw.—T. A. L.

*Machine for Aniline Dyeing Cotton, and Drying Wool, Cotton, and the like; A New or Improved.* T. Ender, A. Kleindienst, J. Proener, Pabianice, Russian-Poland. Eng. Pat. 19,081, Aug. 18, 1897.

The impregnated cotton is introduced into a large rotating drum or cylinder of wire gauze, in which are fitted longitudinal blades or lifters. By means of hot air, supplied by

a fita, the cotton is dried, a lagging or covering is placed over the drum, and the black is developed by blowing steam on to the cotton from a perforated pipe running outside the drum, but parallel to its axis of rotation.

—H. J.

**ERRATUM.**—This Journal, 1897, 908, col. 2. The numbers of the two Figs., I. and II., should be reversed.

## VII.—ACIDS, ALKALIS, AND SALTS.

**Sulphuric Acid Manufacture: Reduction of Chamber Space.** E. Hartmann. Chem. Zeit. 1897, 21, [848], 877.

To reduce the chamber space, Burgemeister considers it practicable to introduce a large number of vertical lead pipes, 40 to 50 cm. in diameter, into the first chamber. These, reaching from floor to roof, induce, in the first place, a stream of cold air, and, in the second place, offer to the gases, surfaces for impact and condensation.

The author, fearing leakage from the many joints, especially on the floor of the chamber, has devised a modification, which he has employed with success since 1893; according to this, these floor joints are avoided. The chamber shafts he makes 1.50 × 1.90 m. in section, and each is luted at the bottom by a water lute. These shafts, open top and bottom, exert a cooling effect, and aid the process by condensing the water vapour to form the water or weak acid necessary to bring about the decomposition of the nitrosulphonic acid.

Several years' experience, it is said, has shown that this modification increases the production of a system by about 20 per cent., and that with it, no difficulty is experienced in working off per 0.9—1 cb. m. of chamber space, 1 kilo. of sulphur in 24 hours. Compared with other arrangements for effecting a like purpose, it possesses the great advantage of being extremely cheap in construction.—J. T. C.

**Sulphuric Acid [in Sulphates], Volumetric Determination of Combined.** Félix Marboutin. Bull. Soc. Chim. 17, [22], 933.

## PATENTS.

**Lixiviating, Steaming, and Atrating: Impts. in.** J. Hargreaves, Farnworth-in-Widnes, Lancashire. Eng. Pat. 23,263, Oct. 20, 1896.

See under I., page 1004.

**Zinc Chloride, Production of, or of Zinc and Chlorine.** E. Hoepfner, London. Eng. Pat. 24,573, Nov. 3, 1896.

Zinc sulphide ores are treated with an acid, or with a solution of cupric chloride or ferric chloride, to extract silver and lead, especially if lead be present in any such proportion as to be injurious in the roasting process which follows. The sulphurous acid evolved in this roasting process, is converted into sulphuric acid, which is heated with sodium or potassium chloride to obtain an alkali sulphate and hydrochloric acid, which acid is digested with the roasted ore. It is preferred that the strong acid should act first upon ore that has already been subjected to acid treatment, in order that ferric chloride may pass into solution, which facilitates the solution of the precious metals, to aid which, chlorine may also be passed in. Finally, the acid solution is digested with excess of the untreated roasted ore. From the solution thus obtained, metals electro-negative to zinc are precipitated by known means, but preferably by electrolysis. Iron and manganese are then separated by chloride of lime, for instance, and the resulting solution of zinc chloride is electrolysed to obtain chlorine and pure zinc, the solution being concentrated when necessary. Chloride of sodium, potassium, calcium, or magnesium, should be present in the solution to increase its conductivity. The application of either the exhaust steam of the steam engines, or of the steam produced on concentrating the solutions, in feeding the sulphuric or other acid-producing apparatus, is claimed.

**Soda, Caustic, or Potash, Caustic: Impts. in the Manufacture of, from Carbonate of Soda, or Carbonate of Potash.** P. J. Worsley, Clifton, Bristol, and The United Alkali Company, Ltd., Liverpool. Eng. Pat. 591, Jan. 8, 1897.

In Loewig's process for the manufacture of caustic alkalis from their carbonates by strongly heating these with iron oxide, "it has hitherto been necessary to lift the materials out of the atmosphere of carbonic acid which is generated," but the inventors have found that this is unnecessary if the materials be well agitated on the bed of the reverberatory furnace. A furnace having a rotating horizontal bed and provided with mechanical agitators, such as a Mactear carbousing furnace, is preferred for this process.—E. S.

## VIII.—GLASS, POTTERY, ENAMELS.

**Glass, Colouring with Silver ("Silberlasur"), and the Cause of the Irregular Behaviour of different Glasses under this Operation.** R. Zsigmondy. Sprechsaal, 28, [39—45]; Dingler's Polyt. J. 306, [4], 91—95.

For colouring small glass articles yellow, the author finds that the ordinary process of applying a mixture of clay and silver oxide to the surface, and then exposing to heat in a muffle, can be replaced by dipping the warmed glass in a flux composed of 20—30 parts of sodium metaphosphate and 4 parts of silver nitrate. As the glass cools down, the coating of colourless flux scales off, leaving the surface of the glass coloured a more or less decided yellow, according to the kind of glass used. The method is unsuitable for large glass articles, the necessary rapid cooling being in such case impossible of attainment.

With regard to the actual condition in which the metal is capable of colouring glass, the author showed, by heating a silvered tube in a current of hydrogen, that the silver is not absorbed in a metallic condition. On the other hand, when heated in a current of air, the oxidised silver is taken up by the glass, but without producing any coloration, this result not ensuing until the oxide is reduced to metal by re-heating in a current of hydrogen. Moreover, experiments with a large number of glasses of different composition, demonstrated the fact that no coloration is developed by the above phosphatic silver flux (or by the aforesaid ordinary method) in pure glass, the colour making its appearance only when ferrous oxide or some other reducing agent (such as metallic lead dissolved in the glass, arsenious salts, carbon, silicon, dissolved metallic sulphides, stannous oxide, &c.) is present. Ferric oxide, in a proportion as large as 2.4 per cent., produced no coloration, whereas the latter developed in presence of 0.95 per cent. of ferrous oxide.—C. S.

**Glass Containing Silver, Surface Lustre in.** —Zsigmondy. Dingl. Polyt. J. 1897, 306, 68—72.

The author some time ago endeavoured to make a glass with metallic lustre, by covering the surface with silver sesquioxide, burning this off in a muffle in an oxidising atmosphere, and then reducing the surface. He has now obtained better results by fusing small quantities of silver nitrate with the materials for making a glass (either borate, silicate, or a mixture of the two), and, while the melt was still

hot, reducing the surface by short exposure to the vapour of alcohol. Borates of sodium, of lead, and of sodium and lead, as also those of cadmium and of bismuth, gave glasses with a fine lustre, some of which also exhibited a blue fluorescence. The borates of barium, calcium, cerium, and antimony gave glasses of too high fusing point to be experimented with, but some of the phosphates gave glasses with lustre. Silicate glasses of the composition—

were prepared, and fused with 1 per cent. of silver nitrate. In all cases the lustre was less pronounced than in the case of the borates, and not so easily or certainly produced. Mixtures were then made of lead borate,  $PbB_3O_7$ , and borax in equal proportions, to which were added varying proportions of the first of the above silicates; and to the glasses so obtained, silver nitrate was added. The best result was yielded by a mixture of 60 grms. of silicate, 20 grms. of the borates, and 1 grm. of silver nitrate. A smaller proportion of silver nitrate gave poor lustre, whilst a larger proportion of borate gave a very fusible and mobile glass, in which, by any overheating, the silver was easily reduced in the crucible, making the glass turbid and preventing the formation of any lustre. The same results were obtained when, instead of adding the silver nitrate to the ready-formed glasses, the whole of the raw materials—sand, litharge, boric acid, silver nitrate—were mixed and melted together. Mixtures of one of these glasses with 1 or 2 per cent. of various metallic oxides (copper, cobalt, manganese) gave coloured glasses, which also showed, on reduction by alcohol, beautiful surface lustre.

The author's view is that the silver in these glasses exists as silicate or borate; that the yellow colour which some of them show by transmitted light is probably due to the reduction of a minute quantity of silver which remains dissolved in the glass; that the lustre is due to silver reduced in a state of almost molecular division in a thin layer of glass, so nearly solid as to prevent the coalescence of the reduced molecules; and that the turbidity so easily produced by too long reducing action at a high temperature or in a very fluid glass, is due to larger particles of silver formed by the coalescence of the molecules first reduced.—J. T. D.

*Glass, Sheet; Melting.* R. L. Die Glashütte, 27, [13], 147.

A USEFUL formula for sheet glass is: Glauber salt, 50 parts; sand, 100; lime or powdered marble, 24; coke or charcoal,  $2\frac{1}{2}$  parts. If the furnace work well, and good fireproof pots be available, an extra 5 parts of sand will improve the quality of the glass, but any larger quantity will make it opaque, hard, and brittle. An excess of lime also produces hard and brittle glass, liable to fracture and difficult to work. On the other hand, an increase of alkali renders the glass softer, more elastic, and easily workable, and is particularly advisable for the cooler classes of furnace. The coke should have been well roasted before grinding, and the quantity must be accurately controlled, an excess causing the glass to froth up during the melting, and to subsequently assume a dark bluish coloration, whilst if too little be taken, the glass will not be clear.

The furnace will require about 2½ hours to become thoroughly heated. The well-mixed glass mass should then be piled up in the centre of the pots, to minimise the risk of cracking the hot sides. Opening wide the flue damper when filling the pots, lowers the temperature considerably and retards the melting. In 6 or 7 hours the second charge of glass mass may be put in the pots, and the remaining portions at subsequent intervals of 3–4 hours. Cullet is thrown in to assist the sandiver to separate, and when this latter makes its appearance (in about 1 hour), it should be burnt off by means of a smoky reducing flame, unless the quantity (as a result of an insufficiency of coke) be very large, in which case it must be skimmed off. When this has been effected, the glass is well agitated by the air-blast to assist clarification. At this stage the temperature requires careful watching, and any pots giving signs of injury must be drawn. As soon as the glass is clear, the

admission of gas to the furnace is stopped, and the latter allowed to cool down sufficiently for drawing the charge.

—C. S.

*Glass, Dull [Frosted] Decorations on Graded.* Diamant, 19, [21], 475–477.

THERE are several ways of producing these decorations. One of them consist in slightly frosting the surface of the glass by applying thereto a mixture of flux, 500 parts; calcined borax, 100; and minium, 300 parts (ground to the proper consistency with oil of turpentine and thickened oil), by the aid of a brush, and then fusing this coating on to the glass at a moderate red heat. An ordinary muffle is less suitable for firing than the continuous furnaces of the Fürbringer type, or the continuous glass-annealing furnace. In the latter, a truckload of coated glass is kept in the first compartment for 10 to 15 minutes, and then passed on to the annealing compartment, where the actual firing takes place. The coating gradually loses its initially red colour and becomes lustrous, the operation being then complete. By dipping the articles in dilute acid for 1–2 minutes (1 vol. of hydrofluoric acid to 4–6 vols. of water is the best medium), the coating and dirt are removed, and the glass is left with a delicate fine-grained dull-lustrous surface. The second stage of the process is effected by means of the sand-blast, the portions to be left in their actual condition being protected from the sand by any of the methods usually employed.—C. S.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

*Blast-Furnace Slag Cement, Notes on the Manufacture and Properties of.* A. D. Elbers. Eng. and Mining J. 1897, 64, [18], 515.

IN this communication the author describes and criticises an article by H. Détienné (Rev. Univ. des Mines, Sept. 1897). The cement experimented with consisted of granulated basic slag which had been dried by heating, and then ground fine in admixture with 15–20 per cent. of “dry-slaked” lime. The composition of the slag should not vary beyond the following limits:— $SiO_2$ , 27–32 per cent.;  $Al_2O_3$ , 12–22 per cent.;  $CaO$ , 49–55 per cent.; and it is preferably dried by heating to about 500° C., or to a dark red heat, this operation involving a consumption of coke amounting to about 9 per cent. of the weight of dried slag. The dried slag is powdered and passed through a No. 80 sieve (76 meshes to the linear inch). The lime is slaked by immersion, all superfluous water being allowed to drop off, so that the slaked mass becomes thoroughly pulverulent; and it is then stored for 8–10 days, in order to dry it so thoroughly that it will easily pass through a sieve of 76 meshes to the inch (it is first passed through a coarse screen, in order to remove the small percentage of incompletely calcined limestone). The cement is prepared by simple dry-mixing. The chief defect in slag cements is the presence of soluble sulphides, and this cannot be overcome by treatment of the slag with nitric acid, as in the case of less basic slags (this Journal, 1897, 680, 800, and 915). Détienné states, with regard to the presence of sulphides, that the granulated slag, as used in the manufacture of the cement, contains from 1–3 per cent. of sulphur in the form of sulphate of calcium and sulphides of manganese and calcium; but in contact with the water used in “gauging” the cement, the calcium sulphide reacts with ferric oxide and forms calcium hydrate and ferrous sulphide. The latter is the cause of the greenish tint observed on the fractured surfaces of fresh briquettes made with slag cement. In contact with the air, the ferrous sulphide is oxidised, but no deterioration is said to occur on this account, since no alteration in volume or texture was observed in briquettes of slag cement after the lapse of four years. The author disagrees with this reasoning, and states that granulated slag, even under the most favourable circumstances, always contains several per cent. of calcium sulphide, and that only a very small portion of the latter is converted into calcium hydrate by the reactions which take place during “gauging,” since these

reactions are merely superficial. He also states that if the briquettes had been kept under water for four years, or had been frequently subjected during that time to varying atmospheric influences, a diminution of strength would have taken place. On admixing small quantities of soda with blast-furnace slag cement, the rapidity of setting is increased (within a range of from 1—2½ per cent.) in proportion to the amount added; an admixture of 14—1½ per cent. of  $\text{Na}_2\text{CO}_3$  is found to give the best results.

—A. S.

*Old Mortar, Examination of.* M. Gary. Mitt. aus den Königl. techn. Versuchsanstalten zu Berlin, 1897, 246.

In connection with the proposed addition to the middle tower of the church of St. Mary at Mühlhausen—a 15th century structure, partly burnt down in 1689—analyses were made of the old mortars. Samples were taken from different parts, and the following results were obtained:—

I. Clay mortar from a part of the foundations.

II. a and b. White lime mortars taken from the walls. The mud obtained on levigation showed, after drying at 100° C., the following composition:—

	North and South Walls.	East Wall.
Insoluble in dilute hydrochloric acid..	13.98	9.69
Loss on ignition.....	37.25	39.81
Lime.....	43.66	46.66
Magnesia.....	0.59	0.81
Oxide of iron, alumina, and silica.....	1.28	2.96

The added grit consisted of calc-tuff sand.

III. Gypsum mortar from a part of the foundations and superstructure. Dried at 100° C., this gave results as follows:—

Insoluble in dilute hydrochloric acid.....	18.61
Loss on ignition.....	12.89
Lime.....	28.25
Magnesia.....	2.61
Oxide of iron, alumina, and silica.....	4.95
Sulphuric anhydride.....	32.39

The added material in the mortar appears to have consisted for the most part of broken tiles, &c., mixed with a clayey calcareous tufa sand.—H. H. B. S.

## PATENTS.

*Cement, The Manufacture of an Improved.* La Société Métallurgique de Champigneulle et Neuves-Maisons, Pont Saint-Vincent, France. Eng. Pat. 1795, Jan. 22, 1897. (Under Internat. Convention, July 11, 1896.)

BLAST-FURNACE slag is first granulated by running it into cold water as it leaves the blast furnace. It is then, whilst still moist, mixed with slaked lime to the consistency of mortar, and left to harden; after which the mass is crushed, baked, and ground. The result is a cement of high resistance, which sets extra rapidly. This is further used for the manufacture of cements which set less rapidly, by grinding it with dried granulated slag and lime.—H. H. B. S.

*Joints, Pipe and other; A Composition or Cement for Making.* S. R. Thompson. Liverpool. Eng. Pat. 27,975, Dec. 8, 1896.

THE composition, which, it is claimed, will expand or contract with the expansion or contraction of the parts joined together, is made of 12 parts of Paris white, 5 of red ochre, 2½ of Venetian red, and ½ part of plumbago or graphite, ground, sifted, and mixed, and made into a stiff paste with boiled linseed oil.—H. H. B. S.

*Wood, Impts. relating to the Impregnation of, and Apparatus therefor.* G. F. Lebiouda, Paris. Eng. Pat. 30,055, Dec. 30, 1896.

THIS invention consists of an injector, by means of which wood can be impregnated with solutions for staining purposes, &c., without the necessity of boiling, which is said to ruin the texture of the wood. The apparatus consists of a compressing chamber and a suction chamber, which are superposed, but separated by a perforated partition. The

blocks of wood to be impregnated are fixed in an upright position by means of tightening screws in the compressing chamber, with their lower ends resting upon the perforated partition. The holes in the partition not covered by the wood are stopped by plugs, and melted pitch or similar substance is poured in, so as to run between the blocks and cover the partition to the depth of a few cm. By this means a tight joint is formed between the lower edges of the wood and the partition. The liquid is then forced longitudinally through the pores of the wood by the combined and simultaneous action of the compressing and suction chambers, operated by a suction and force pump.

—H. H. B. S.

*Sand, Cement, and other similar Substances; Impts. in Apparatus for Measuring and Mixing.* H. Alexander, Leeds. Eng. Pat. 13,506, June 1, 1897.

See under I., page 1005.

## X.—METALLURGY.

*Titaniferous Iron Ores, Utilising.* A. J. Rossi. Eng. and Mining J. 1897, 64, [19], 550. Read before the Amer. Inst. of Mining Engineers.

THIS paper relates to the author's U.S. patent for the utilisation of titaniferous iron ores in connection with the smelting of ores rich in phosphorus. It is claimed that by the admixture, prior to smelting, of a certain quantity of titaniferous ore, a strong, tough iron can be obtained, even when the amount of phosphorus present amounts to as much as 3 per cent.—A. S.

*Iron, nearly Pure, Influence of Sudden Cooling on.* A. Sauveur. Eng. and Mining J. 1897, 64, [17], 189—490.

THE author traverses the statement by Arnold (Engineering, July 6, 1897) that the critical thermal points  $\text{Ar}_2$  and  $\text{Ar}_3$  are, as such, without influence on the mechanical properties of steel, and quotes Arnold's own experiments as proof of the direct contrary; and further, he uses the same figures in controversion of Arnold's statement that between 500° and 900° C. the increase of tenacity is proportional to the quenching temperature. As a matter of fact, the temperatures 650°, 780°, and 987° C. are evidently marked out as special points; and this is conclusively shown by the following table:—

Quenching Temperature.	Tenacity after Quenching in Tons per sq. in.	Position of Quenching Temperature with regard to Critical Points.	Total Increase of Tenacity in Tons per sq. in.	Mean Increase of Tenacity for an Elevation of 1° C. of Quenching Temperature, in Lb. per sq. in.
° C.

—W. G. M.

*Molybdenum-Steel, Some Properties of.* W. v. Lippin. Stahl u. Eisen, 1897, 17, 572; through Chem. Zeit. Rep. 1897, 26, 295.

THE influence of molybdenum on the properties of steel is commonly supposed to resemble that of tungsten. The author has compared two blocks of crucible steel, one containing 3.72 per cent. of molybdenum (with 0.55 C, 0.1 Si, 0.13 Mn, 0.024 P, and trace of sulphur) and the other 3.82 per cent. of tungsten (with 0.55 C, 0.07 Si, and

0.13 Mn). The metal did not rise on pouring; the slag of the molybdenum steel was half vitreous, greenish-grey, and showed a play of colours. For smith-work, both steels must be heated. Molybdenum steel exhibits a perfectly smooth surface, whilst the harder tungsten steel often shows minute cracks. Tests of the two steels were made, after treatment in various ways, by hardening and annealing. Strongly annealed molybdenum steel is softer than tungsten steel of the same composition. Heating to a very high temperature, such as is good for chrome or carbon steels, is unsuitable for molybdenum steel, whilst hardening in oil and subsequent annealing, which improves other kinds of steel, is almost useless for it. The usual method of hardening in oil has more influence on tungsten steel than on the sample containing molybdenum, but more energetic hardening in water acts in the opposite direction.—W. G. M.

*Argentiferous and Auriferous Lead, Notes on the Sampling of.* A. C. Claudet. Read before the Inst. of Mining and Met., Oct. 20, 1897.

It has been found that different parts of the same bar of lead carrying silver or gold, vary very much in their contents of these metals, and this circumstance affects the sampling of argentiferous and auriferous lead bullion on the large scale. The surface of a bar is, as a rule, poorer in silver and gold than the bottom, but when the gold contents become high, the reverse appears to be the case. The ordinary methods of sampling are as follows:—(1.) Cutting chips out of the tops and bottoms of the bars. (2.) Sawing, by a circular saw, through the bars. (3.) Melting the bars in mass into clean lead and dross.

In *System (1)*, chips are cut by a gouge or chisel out of the top and bottom of every bar, or alternately the top of one bar and the bottom of the next. The chips are melted, either together into one bar, or those from the tops and bottoms separately into two bars. On assaying the bars, the results are compensated for enrichment on melting, if necessary. This method should only be employed with lead containing 10–20 oz. of silver per ton.

*System (2)*—The bars are sawn transversely, either half way or right through. The sawings are either melted into small bars and assayed, or they are assayed without melting; in the latter case, the result must be corrected for impoverishment, due to the oil which has to be used when sawing the bars. The teeth of the saw should be rather small, to prevent too frequent breakages and to produce small-sized sawings. This method may be satisfactorily used with lead containing silver up to 100 or 200 oz. per ton.

*System (3)*—The lead is melted in large iron pots, holding from 10–30 tons; the charge is heated and skimmed until the molten lead is quite clean; the temperature is then raised as high as possible, the lead well stirred up, and a “dip” sample taken. The dross is broken down when cold and a sample taken. The two samples are then assayed, and the results corrected and calculated with regard to the original lead charge. This method takes the longest time, but is stated to yield the most reliable results; it should be employed in all cases where the silver is above 200 oz. per ton, and where the gold is above 1 or 2 oz. per ton. Nine plates accompany the paper, fully illustrating the precise methods of obtaining samples by cutting or sawing the bars.—A. S.

*Gold, Action of Potassium Zinc Cyanide Solutions on.* W. J. Sharwood. Eng. and Mining J. 1897, 64, 396, 426, 460–461.

The author, after a large number of experiments, arrives at the following conclusions:—The gold-dissolving power of a solution of potassium zinc cyanide increases with a rise of temperature, slightly with strength of solution, and rapidly with increased access of oxygen; the presence of the latter is the most essential condition. It is also increased by the addition of alkali, the increase being greatest in solutions to which oxygen has free access. Gold dissolves in the solution of double cyanide to a clear solution at first, but after some time a white precipitate forms, gradually coating the metal and retarding further action.

The amount of precipitate formed is not proportional to the gold dissolved, but is relatively less when the amount of solvent is large; it consists of a somewhat variable mixture of the cyanide and oxide of zinc. The solvent action of a solution of potassium zinc cyanide is less than that of a solution of potassium cyanide containing the same amount or half the amount of cyanogen. The considerable increase in solvent power observed when caustic potash is added (oxygen being easily accessible) to potassium zinc cyanide seems to indicate the formation of free potassium cyanide, and consequently that in dilute solutions (0.3 to 0.6 per cent.) potassium zinc cyanide is partially decomposed by alkalis; this is confirmed by the fact that on mixing solutions of alkali and potassium zinc cyanide, a slight fall of temperature occurs (Ellis, this Journal, 1897, 16, 116). Reference is also made to the articles of W. R. Feldtmann (this Journal, 1894, 218 and 952); W. H. Virgoe (Eng. and Mining J. 1894, 58, 314; this Journal, 1894, 739); G. A. Goyder (this Journal, 1894, 523); J. S. C. Wells (Eng. and Mining J. 1895, 60, 584, and 1896, 61, 179; this Journal, 1896, 116); N. Anderson (Proc. Colorado Scient. Soc., April 1895); and Bettel (Chem. News, 1895; 72, 298).—A. S.

*Gold Extraction, By-Products from.* C. Butters. Proc. Chem. and Metall. Soc. of S. Africa, Meeting of Sept. 18, 1897, 14–20.

*By-Products from Stamp Mills.*—Inside and outside copper plates, the screens through which the pulp passes, rags and brushes used in cleaning the plates, screen frames, mortar-boxes, shoes and dies, all tend to retain amalgam. The clean-up gives plate-scrappings, including gold amalgam, particles of iron and copper, sand, iron pyrites (especially magnetic pyrites when present), a little grease, and coloured filts and other sulphur compounds. The amalgam is cleaned by grinding and washing, generally in an amalgamating barrel, with such chemicals as lime or cyanide of potassium. The ashes from the rags, &c. (which are burned to remove organic matter), together with sealings and any other matter that may contain amalgam, are placed also in this receptacle, which is usually a grinding barrel, and the mixture ultimately yields fine silica, slime, and water containing chemicals. At the best mills these products are further treated, because some of the mercury will have floured, some of the hard amalgam will have become finely crushed, and some of the rest will have become floured in the grinding of the pyrites, whilst in the presence of cyanide, some gold will have been dissolved. Hence the slimes are carefully settled, and the liquid is run into a collecting tank containing any scrap iron that is likely to carry gold, and is here acidified with sulphuric acid. The sludge from this tank, together with the slimes, will contain from 50 to 300 oz. of gold to the ton; the former is cleaned up once or twice, the latter twice or four times in the year, according to the size of the mill, the products being sent away for treatment. From 40 to 50 oz. of gold may thus be easily obtained per mensem from a 100-stamp mill, although in many mines these materials are run to waste. The screens, after being rusted and beaten, retain about 2 oz. of gold per ton; they may be used as blast-furnace flux, or worked up for ferrous sulphate in chlorination works, the resulting sludge being afterwards treated. Worn-out copper plates, even after most careful scaling, should always be retined, as the value of the gold contained, is at least equal to that of the copper. Iron battery chips also contain amalgam even after cleaning. These chips, screens, and old iron generally may be efficiently and cheaply rusted by placing alternate layers of screens, chips, and clean concentrates (containing as much sulphur as possible) in a warm place, near a boiler-furnace, or under a glass frame (like a gardener's forcing-house), and watering the heap frequently with warm water and salt for from four to six weeks. The whole is then dried and run through a ball-mill, and the product may be used as blast-furnace flux, any iron that is not rusted through, being so deeply scaled as to be free from amalgam.

*By-Products from Cyanide Works.*—These by-products are much less in quantity from fresh than from oxidised pyritous ores. In the latter case ferrous and ferric salts are

formed, and tend with cyanide and alkali to produce ferrocyanides and hydroxides, which diminish the efficiency of chemical precipitation and increase the amount of sludge from electrical precipitation boxes. Moreover, the lime required for acid ores passes into solution as hydroxide, carbonate, or sulphate, and these crystallise out in the precipitation boxes. Lead cathodes thus become encrusted with lime salts, which gradually slip off and carry gold with them into the sludge, and increase the proportion of gold carried in suspension. In zinc precipitation any deposit in the boxes is treated in the clean-up, but the complex cyanides, clay, humus, and flocculent precipitates held in suspension always carry gold with them, which may be in part deposited in the sump. With fresh ores the filtration of the still suspended residue should not pay, but with acid ores the material may retain from 1 to 20 oz. per ton. The sludge from the sumps should be removed at intervals, air-dried, and sold to smelting works. Except after roasting or other suitable treatment, such precipitates do not readily yield their gold to cyanide solutions.

**By-Products from Siemens-Halske Precipitation Boxes.**—The iron anodes gradually oxidise and form Prussian blue and ferric hydroxide. These partly sink to the bottom and partly float through into the sump, where by degrees they become peroxidised. The sacking surrounding the anodes, becomes saturated with the same deposit and, after a time, rotten, and is removed and burnt, whilst the anodes are carefully sealed. In a sand plant, working with clear solutions, all this Prussian blue may contain from 5 to 50 oz. of gold per ton. But in a slime plant the precipitate becomes contaminated and has a lower value. Any precipitation process is handicapped by the mass of suspended matter, and the author is now constructing sand filters for clarification, prior to precipitation. When sand and slimes are worked together, as at the Bonanza, clarification can be largely effected by passing the solutions through the sand vats. The precipitates formed in the vats are far less prejudicial than silica or clay, i.e., to the ton of silicious slime sufficing so to coat anode and cathode that gold does not adhere properly and a higher voltage is required.

**Siemens and Halske Melting-Room By-Products.**—When the lead is fairly clean and free from silicious mud or iron salts, the melting in the reverberatory furnace (5 ft. by 2 ft. 6 in.) is rapid, and a little coal is spread over the surface, while the temperature is urged to the utmost possible extent. Clean lead with 5–10 per cent. of Au is obtained, together with either a liquid litharge slag or (with dirty strips) pulverulent "skimmings." If more than one melt be required for a clean-up, the old skimmings are sweated of their lead contents, as far as possible, in the second charge. The hot liquated skimmings are then drawn, cooled, ground under a Chilean edge-roller, and screened through a mesh with eight holes per linear inch, whereby two grades are formed, known as "coarse metallies" and "ground skimmings." The former are melted in iron pots and run into bars, which are counted as lead bullion, whilst the skimmings form by-products. The lead from the reverberatory is also re-melted, and the skimmings from these pots are added to those from the furnace. The amount of gold in the skimmings may, with care, be reduced to under 1 per cent. The expellation of the bullion produces about  $\frac{1}{2}$  per cent. of "refinery by-products."

**Chlorination Works By-Products.**—The only by-product here is the sludge, cleaned up once or twice a year, from the second set of precipitation vats. Ferrous sulphate precipitation from chlorine solutions is incomplete in the presence of some salts, and there is always gold in suspension. In some cases the liquid is drawn off after 24 hours, in others after 48, but in the author's works after 72 hours; even then the assay value is from 4 to 12 grains, unless there is much copper or lime present, when it may even be as high as 2 dwt. Hydrogen sulphide precipitation gives the lowest and therefore the best results in this respect, and the acid liquor drawn off from the gold and placed in tanks filled with scrap-iron, decomposes rapidly, yielding a precipitate of gold, copper, and basic iron sulphates and hydroxides. In a cold climate the vats should be enclosed in a house and slightly warmed by steam. The liquor may be run to waste, assaying less than

2 grains after a week. The sludge from these final precipitation vats is worth from 1s. to 8s. per ton of ore treated, and in California yields from 2 to 2½ per cent. of the total gold obtained in the chlorination works. The by-products from melting the slimes, which should be nearly pure gold, are necessarily few, the slag produced being treated of in the next division.

**By-Products from the Melting Room.**—The slime taken to the melting room after sulphuric acid treatment and washing, may contain from 25 to 50 per cent. of gold. Loss is incurred in handling this or the precipitate from the zinc boxes (on both the hands and the tools in mixing with fluxes), in transferring to the crucible, in the slag, in the mould, and in the sink where the bar is scrubbed, but this loss may be for the most part temporary. Every melting room should be provided with two 100 to 200 gallon tanks, into which all washings from hands or tools, and from the sink, are thrown. After four or five months the liquid is assayed and drawn off, and the precipitate is cleaned up; 200 oz. of gold have thus been recovered from one tank. The pots may be sealed and the sealings melted after grinding, but even then the pots will retain 20 to 40 oz. per ton. Ashes and flux-dust from the melting furnaces may be cleaned up, the former averaging 5 oz. per ton, and being (with the pots) the most refractory material to be treated. Slag from melting zinc-gold slimes assays from 25 to 200, but averages 50 oz. of gold per ton. When the zinc slimes have been treated by the acid process, the thin lead matte found on the gold after pouring, contains about 11 per cent. of Au. The melting or roasting furnace itself becomes saturated with gold, and the old masonry of a renovated furnace will commonly assay 20 oz. per ton; where, however, only mill-gold is melted, only the immediate lining of the furnace is valuable. In panning ground slags for coarse gold, 20–25 per cent. of the slag form slimes, which are frequently allowed to run to waste, but which should be saved by allowing the water to stand in tanks until subsidence is complete, for the fine material is as rich in gold as the coarse. The floor of the melting room should either be of iron or be cemented, and should be kept scrupulously clean, the sweepings being saved, as they always assay over 5 oz. of gold per ton.—W. G. M.

#### *Copper, Impurities in Raw.* M. Schlagdenhauffen. Comptes Rend. 125, [16], 573–574.

FILINGS of crude copper, such as Chili bar or English blister, were allowed to remain in water for several days, when, after filtering and slightly acidifying, the water yielded, with hydrogen sulphide, yellow and orange-yellow precipitates of sulphides of arsenic and antimony. If the same sample, after complete exhaustion with water, be treated with potash or dilute hydrochloric acid, a further and larger quantity of arsenic and antimony is dissolved out. Thus arsenic and antimony may probably be present in the form of oxides.

When similar filings were heated in a combustion tube in a current of carbon dioxide, a crystalline sublimate was obtained, containing arsenic and antimony. Further experiments, however, tend to show that the arsenic and antimony are not wholly present as oxides.

With other samples of copper the author has detected selenium in the sublimate by means of the red precipitate with sulphurous acid and by the red ring produced on sublimation in the presence of ammonium chloride. The author believes this to be the first time that selenium has been detected in raw copper. Also by heating copper in a tube, he has obtained a sublimate of cubical crystals of lead sulphate.—A. W.

## PATENTS.

*Lead, Zinc, Gold, Silver, and other Metals: Impts. in the Extraction of, from Sulphides, Refractory or other Ores, or Mattes.* J. Armstrong, London. Eng. Pat. 22,361. Oct. 9, 1896.

REFRACTORY sulphide ores or mattes containing zinc are heated with carbonate or nitrate of soda or potash, lime, and carbon in a reducing atmosphere, in a furnace with a sloping bed. The charge melts and separates into three layers, i.e., metal, a slag of calcium silicate, and a top brittle layer of a mixture of zinc, zinc salts, and soda salts. The latter is further distilled in a closed furnace for zinc, and the residue therefrom extracted with water to recover sodium sulphide, which is re-converted into carbonate for further use. The lime slag is also lixiviated with water for the same purpose.—A. W.

*Furnaces, Cupellation: Impts. in the Beds or Tests of, and of Assay Cupels and the like.* T. B. McGhie, London, and E. G. Ballard, Chester. Eng. Pat. 26,493, Nov. 23, 1896.

Barium sulphate is to be substituted for bone-ash; the mineral barytes is crushed, and moulded under pressure, with or without water. To prevent cracking of the finished cupel, the material should be calcined before use; it may, with advantage, be mixed with 5–10 per cent. of Portland or other lime cement. For the lining of improving furnaces or the like, 3 parts (by measure) of barytes may be mixed with 1 part of cement, the mixture being gauged with water and laid on with a trowel. Sodium or potassium sulphate may be used as a binding medium. When the tests are saturated with lead, they are fluxed with fluorspar, and smelted.—W. G. M.

*Aluminium, Impts. in the Purification of.* P. E. Placet, Paris. Eng. Pat. 28,727 (under Internat. Convention). Dec. 15, 1896.

MOLTEN aluminium is placed in a crucible or furnace lined with magnesia, and is there stirred vigorously with potassium bichromate. The impurities in the aluminium are thus said to be removed in combination with the oxygen of the bichromate, and the chromium thus introduced into the aluminium improves the qualities of the metal. When the reaction is complete, a flux of chlorides, chromates, or fluorides is to be added. Other bichromates may be substituted for the potassium salt, the bichromates of nickel, copper, or other element being employed when one of these latter metals is ultimately to be alloyed with the aluminium. Permanganates or chlorates may be employed, or nitrates, excepting those of potassium, sodium, or ammonium (which act prejudicially upon the aluminium).—W. G. M.

*Furnaces for Smelting Ores and Melting Metals by means of Liquid Fuel, Impts. in.* L. Pietraschewski, Borisso- glebsk, Russia. Eng. Pat. 29,467, Dec. 22, 1896.

A REVERBERATORY furnace is arranged with a vertical shaft and chimney at one end, and a sump with tap hole in the centre, the bed sloping gradually from the shaft to the sump. At the other end of the furnace is a heating chamber with a row of liquid fuel burners projecting the fuel along the main axis of the furnace. The fuel is supplied from a high-level reservoir at one side of the furnace, and is passed through a regulator, which enables the pressure of the liquid to be maintained constantly a little higher than the back pressure in the furnace. Air is blown in through the burner by a fan-blower, and may be

pre-heated if desired. The ore or metal is fed into the shaft through a charging door, and the molten material afterwards flows into the sump, from which it is tapped as required. In this furnace, cast iron may be melted in about 20, or steel in about 40 minutes from charging. A furnace capable of melting 1,600 kilos. per hour requires only two attendants. Where a metal is to be decarburised, an automatically regulated stream of liquid fuel is to be turned into the shaft. The regulator consists of a float with a spindle valve at its end, in combination with an outlet having a valve seat, for the liquid fuel.—W. G. M.

*Furnaces, Crucible: Impts. in.* J. S. V. Bickford, Falmouth. Eng. Pat. 29,705, Dec. 24, 1896.

THE crucible is placed in a circular chamber with an outlet to a flue at one side, near the bottom. A lid covers the chamber, and through it, a vertical blowpipe is passed so that its flame is projected into the middle of the crucible. The blowpipe consists of a T-tube, with the cross tube vertical, one end passing through the furnace lid and remaining open, whilst the other end is plugged, except for an air injector of smaller bore which passes into it. The lateral tube is supplied with a mixture of air and gas by a second injector. Around the central aperture in the furnace lid is a series of smaller holes (which may be opened or closed at will) for the admission of air, so that a flame may play around as well as into the crucible.—W. G. M.

*Crucible Melting Furnaces, Impts. in.* W. Kirkham, Sheffield. Eng. Pat. 29,709, Dec. 24, 1896.

THE object of this invention is to dispense with separate or detached regenerators by so constructing the part of the gas-heated crucible furnace in front of the pot holes, that the heat from the latter is utilised in heating the air and gas previous to combustion. This is carried out by arranging a series of pot holes side by side with a straight front, along which is constructed, in the brickwork, the tubes supplying the air and gas, with suitable valves for shutting off or directing the gases into any particular pot hole as may be required.—A. W.

*Cyanides and other Products, Impts. in Obtaining from Blast Furnaces.* A. K. McCosb, Coatbridge, Lanark, N.B. Eng. Pat. 381, Jan. 6, 1897.

APERTURES are made through the boshes of the blast furnace at a height of from 8 to 12 ft. above the tuyer level, through which gases are withdrawn and washed, ammonia and cyanides being obtained from the liquors. The pipes passing through the apertures open into a large pipe, encircling the furnace, connected to a main leading to the washing apparatus and fan, and also through a stop valve to the furnace blast pipes, so that, if required, air can be admitted from the pipes.—E. S.

*Aluminium, Impts. relating to.* H. Griffith, jun., Birmingham. From V. Coppée and A. E. Kemplen, Paris. Eng. Pat. 6991, March 17, 1897.

THE resistance of aluminium is to be so increased that the metal shall be available for the construction of cycle components, &c. The aluminium is melted in a steel crucible in such a way that no flame shall come into contact with the surface of the metal; about 0.5 to 2 per cent. of tungsten, which has been mixed into a stiff paste with borax, and moulded into cakes, is plunged to the bottom of the crucible. So much gas is thus evolved that when the maximum amount of tungsten is to be added (to produce the most highly resistant metal), it should be introduced in two batches. When the agitation of the metal has ceased, the contents of the crucible are well stirred and poured into moulds.—W. G. M.

*Aluminium, Brazing of; Impts. relating to.* H. Griffith, jun., Birmingham. From V. Coppée and A. E. Kemplen, of Paris. Eng. Pat. 6993, March 17, 1897.

50 PARTS of zinc are fused with 10 parts of tin or bismuth, and cast; the resulting plates are then rolled to the thickness of about 2 mm., and electro-plated with nickel or silver, after which they are subjected to hammering or

compression. The parts of aluminium to be brazed are heated sufficiently to melt the ends of the soldering strip when placed in contact with them. When they have thus been coated with the solder, they are held together at a temperature sufficient to flush the solder, and are finally cooled.—W. G. M.

*Metals [Antimony, &c.], Improved Method of and Apparatus for Extracting from their Ores or other Compound Bodies containing them.* W. G. M. Foote, Sydney, Australia. Eng. Pat. 14,438, June 15, 1897.

THE ore is mixed with lime (either anhydrous or hydrate) and carbon, and heated in long muffle-shaped fireclay retorts from the outside. The beds of the retorts, instead of being flat, slope downwards from the centre towards a longitudinal channel at each side, and the whole retort slopes from one end to the other, so that any molten portion of the charge will flow along these channels to the lower end of the same. At this end, which is at the back of the furnace, is constructed a well with a tapping hole at its base, which acts as a reservoir for the molten metals and slags during the periods between the tappings. It is not necessary that all the gangue should fuse into slag, as the retorts may be used for processes, such as antimony extraction, where the metal is obtained by liquation.—A. W.

*Sulphide Ores [Zinc], Impts. in the Treatment of Complex, and Apparatus therefor.* F. Ellershausen, London. Eng. Pat. 16,808, July 15, 1897.

IN treating complex sulphide ores, 100 parts are mixed with about 50 parts of oxide of iron or manganese, and 25 parts of carbon, and the whole is maintained at a bright red heat in a reverberatory or other suitable furnace. Fumes of lead, zinc, and sulphur dioxide are produced, and are carried, together with the fire gases, into a chamber, where they are met with air and water, by which means the metallic fumes are converted into soluble zinc sulphate and insoluble lead sulphate. The former is separated by solution, and the latter, which may contain silver, is mixed with the fused residue of the furnace charge to produce a mixture suitable for smelting in the blast furnace.—A. W.

*Aluminium, An Improved Process of Soldering.* F. George, Laeken-lez-Bruzelles, Belgium. Eng. Pat. 18,731, Aug. 12, 1897.

THIS process is to solder aluminium by means of aluminium itself. A bath is prepared consisting of 1 part of sea salt or common salt, and 2 parts of turpentine or other hydrocarbon. The parts to be soldered are heated to dull redness and cooled in this mixture, which treatment is said to modify the molecular condition of the metal. After cooling, the parts are lightly powdered with borax, and aluminium in a state of fusion is interposed, whereby the soldering is effected.—A. W.

*Amalgamating Pan, An Improved.* E. H. T. Plant and S. Dellow, both of Charters Towers, Queensland, Australia. Eng. Pat. 19,480, Aug. 24, 1897.

THE pan is made of cast iron with a slope at the centre, then a flat bottom about half an inch in depth, and a deeper recess round the circumference to collect the amalgam. A metallic muller, slightly less than the diameter of the pan, floats on the mercury which covers the bottom, and rotates by means of arms which are keyed to a revolving shaft which rises through an opening in the centre of the pan. The crushed ore and water are fed into a cylindrical casing above the centre, on to the sloping portion of the pan, and thence between the muller and the flat portion containing the mercury, to a sloping shoot at the outer edge.—A. W.

## XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

### (A.)—ELECTRO-CHEMISTRY.

"Nitroguurete." H. Pauli. Zeits. f. Elektrochem. 4, [5], 1897, 137—139.

UNDER the above title, Grove described in the Phil. Mag. for 1841 a series of remarkable metallic compounds con-

taining nitrogen, which were supposed to have been obtained by electrolysis. The electrolyte contained an aqueous solution of an ammonium salt. As positive poles he used successively zinc, cadmium, and copper. The object was to liberate at the cathode the metallic gas simultaneously with ammonia and hydrogen, and to cause them to unite. No details of the current-density are given, but as a source of current he used six of the cells known by his name. The salt of ammonium employed, was sal-ammoniac (in concentrated solution). Grove's results are quoted without question in various text-books, *Ac. Org.* Gmelin-Kraut, Thorpe, Pogg. Ann., Watts' Dict., &c. But Aslanoglu (Chem. News, 64, 313, 1891), in endeavouring to prepare the copper compound according to Grove's method, arrived at quite different results. At Prof. Landolt's suggestion the author has made experiments on the supposed zinc compound, and he confirms Aslanoglu's results, to the effect that the supposed copper-nitroguarete consists simply of copper and cuprous oxide, its colour varying from dark brown to red.—D. E. J.

### PATENTS.

*Electrical Batteries, Impts. in.* Zinc, Lead. C. E. O'Keenan, Paris, France. Eng. Pat. 27,167, Nov. 30, 1896.

NEGATIVE plates which have been charged in the usual way are exposed to the air to oxidise them. They are then placed in dilute sulphuric acid until the formation of sulphate of lead ceases, when they are rinsed in water, which may contain a little carbonate of soda to neutralise any free acid that may adhere to them, and they are then set up in a battery, in which the acid is replaced by sulphate of zinc and the peroxide of lead by zinc plates. When the E.M.F. falls, the lead plates are again exposed to the air to oxidise them, and treated as before. The electrodes may be formed in the battery itself, if lead plates containing chloride of lead pastilles are employed. When the reduction is complete, the plates can be used as ordinary and well formed plates. As the battery works, the density of the sulphate increases, and the dense liquid is displaced into a system of pipes communicating with a supply of water and the battery, so that it is diluted to the proper extent, the equilibrium of the liquids in the tubes being in inverse ratio to their densities.—G. H. R.

*Accumulators, Lead; Impts. in.* A. Dodd, Wolverhampton. Eng. Pat. 28,139, Dec. 9, 1896.

"A PLATE . . . composed of lead strip or ribbon, having, preferably, corrugated surfaces, or surfaces of like character mechanically produced, with several thicknesses of the strip or ribbon placed vertically together, face towards face, and their upper ends joined with a bar or suspender by soldering or burning, or by casting the bar or suspender thereto." &c. &c.—J. C. R.

*Batteries, Secondary, Electric Accumulators [Perchloric Acid]; Impts. in the Manufacture of.* L. Lucas, Hagen, Germany. Eng. Pat. 28,511, Dec. 12, 1896.

"THE process of forming accumulator plates . . . consisting in employing therefor—instead of chloric acid, hydrochloric acid, and the like—the more stable perchloric acid or its salts . . ." "The perchlorate is added in such proportion to the sulphuric acid that the solution shall contain about 5 to 10 grms. of perchloric acid liberated by the sulphuric acid (from perchlorate of potassium, sodium, or calcium)."—J. C. R.

*Electric Accumulators, Impts. in the Manufacture of.* [Grid.] F. Pescetto, Turin, Italy. Eng. Pat. 18,430, Aug. 7, 1897.

THE holes in the grid are jagged three times, at 90° apart, on both sides of the plate, so that the metal projects inwards over the openings, which are then filled with a paste composed of minium or litharge, mixed with 5 per cent. to 10 per cent. of ultimate of ulmin, preferably prepared according to Eng. Pat. 13,092, 1887. The ultimate,

which should be of the consistency of putty, must not exceed "1.5 degrees of acidity."—G. H. R.

*Electrolytic Apparatus [Tanks, &c.], Impts. in.* H. S. Jones, London. From E. Balbach, jun., Newark, New Jersey, U.S.A. Eng. Pat. 19,035, Aug. 17, 1897.

1. "The combination of a cathode case, composed of a trough having its bottom divided into two portions, one of which is horizontal and the other of which is inclined, so as to slope down to and connect with the horizontal portion, throughout its length, and provided with a cathode plate; and an anode suspended therein, arranged to cover the horizontal portion of the bottom only." The object is to construct apparatus so "that the metals which it is desired to separate can be easily and readily removed from the bath, without in any way interfering with or stopping the electrolytic separation."—J. C. R.

*Electric Furnaces, Impts. in. [Fixed Arc.]* W. S. Horry, Michigan, U.S.A. Eng. Pat. 22,521, Oct. 1, 1897.

See under II., page 1006.

### (B.)—ELECTRO-METALLURGY.

*Separation of Metals, Studies on the Electrolytic.* A. Waller. Zeits. f. Elektrochem. 1897, 4, [10], 24.

See under XXIII., page 1042.

### PATENTS.

*Magnesium and its Alloys, Impts. for the Manufacture of certain Metals and Alloys, especially for the Manufacture of.* A. Le Redotte, Paris, France. Eng. Pat. 21,976, Oct. 3, 1896.

In this process for the electrolytic production of magnesium, lithium, chromium, and their alloys, which is specially described with reference to the first-named metal, special care must be taken in the drying and fusion of the magnesium chloride, which is assisted by the use of hydrate of ammonium in a manner fully described. The fused chloride is run into the electrolytic vessel, which is provided with a luted cover, through which a movable anode passes, the cathode being fixed to the bottom of the vessel or formed by a carbon lining. An arc is struck between the two electrodes in the body of the electrolyte, and the production of magnesium is carried on both by electrolytic action and by the dissociation produced by the high temperature of the arc. To prevent the reunion of the gases with the metal, they are carried off through a flue formed by the interspace between the anode and a surrounding sheath of some refractory substance, preferably carbon. This sheath is perforated to allow of the introduction of an inert gas, such as nitrogen, to sweep away the gas evolved in the electrolytic process; and means are provided for the introduction of fresh salts, and the removal of the molten metal, which is kept surrounded by an inert atmosphere.

—G. H. R.

*Calcium Carbide, Manufacturing [Electrolytically], and for the Reduction of Metals from their Oxides; An Improved Method and Apparatus more especially intended for.* H. Maxim, London. Eng. Pat. 25,611, Nov. 13, 1896.

THE claims relate to (1) "Establishing electrical connection between an electric incandescence heating conductor and an electrode connected with one of the poles of a source of electrical energy, whereby a yielding or sliding contact is provided." (2) "An electric incandescence heating conductor extending through and capable of longitudinal movement in a tube or other suitable material for establishing electrical connection between such conductor and the said tube or receptacle, or other suitable electrode or terminal, whilst permitting the required longitudinal movement of the said conductor." (7) "The process of making calcium carbide, which consists in fusing the carbide-forming material by the heat of combustion, and converting the said material into carbide by the aid of

electricity." (8) "The superheating of previously heated fuel-gas and air by the combustion of a portion of such heated or superheated gases, &c." (9) "In the manufacture of calcium carbide, the herein described process, consisting in heating separate currents of air and fuel-gas [water-gas, &c.] by passing them through heating furnaces, in the first of which fuel-gas is burned, and in the second or succeeding furnace, they are superheated by the combustion of a portion of the highly heated or superheated air and fuel-gas, and then burning the superheated gases or the remainder thereof for heating the carbide-forming materials."—J. C. R.

*Zinc Chloride, Impts. in Apparatus for use in Electrolysis, more especially intended for use in the Electrolysis of. [Rotary Cathodes.]* F. Hurter and the United Alkali Co., Ltd., Liverpool. Eng. Pat. 28,764, Dec. 15, 1896.

THE apparatus consists of a tank divided by means of frames into a number of compartments alternately open and closed at the top, the former containing the cathodes and the latter the anodes, which are separated from them by suitable diaphragms. The cathodes consist of vertical cylinders, preferably of iron, provided with pivots at each end, resting in sockets, and so arranged as to be capable of turning round, or partially round, a vertical axis. Connection is made with the carbon anodes through the sides of the tank, and openings are provided in the respective compartments for the circulation of the electrolyte and the removal of the gases. The deposit is stripped from the cathodes by submerging them in a molten bath of the same metal.—G. H. R.

*Cathodes [Plumbago], Impts. in or relating to, employed in Galvanoplastic or Electrotyping Processes.* A. Julien, Paris, France. Eng. Pat. 88, Jan. 1, 1897.

IN place of oil or fat it is proposed to employ essence of turpentine, benzine, "petroleum essence," petroleum, alcohol, xylene, or the like, as an admixture to plumbago for the coating of cathode surfaces, preferably in the proportion of 100 to 250 grms. of plumbago to 1 kilo. of the "essence of turpentine." This suffices for deposits on plane or semi-spherical surfaces, but for round or spherical surfaces it is better to add to the mixture a proportion of resin (colophony), gum arabic, yellow wax, paraffin, Canada balsam, or the like, according to the hardness and adhesion required.—G. H. R.

*Batteries, Secondary [Cadmium, &c.], Impts. in.* C. E. Lee, Chicago, U.S.A. Eng. Pat. 10,439, April 27, 1897.

A CELL is described with a "porous cup" containing the anode of lead surrounded with the active material (lead oxide), and a cathode of amalgamated copper gauze contained in an outer jar, the whole arranged concentrically. The electrolyte employed is a ["neutral salt without any associated acid"] solution of cadmium sulphate "of 27° to 30° B." "Metallic cadmium is produced, and deposited on the negative element evenly."—J. C. R.

## XII.—FATS, OILS, AND SOAP.

*Earth-Nut Oil.* S. P. Sadtler. Amer. J. Pharm. 1897, 69, 490—492; Analyst, 1897, [260], 284.

THE author states that when earth-nut oil is freed from the acid which is present in the raw state, it does not tend to become rancid so readily as olive oil, and he recommends its use in pharmacy, as the products are equally good, whilst the cost is much less. The bulk of the Castile soap manufactured in Marseilles is stated to be made from African earth-nut oil.

The cold-pressed oil is of a pale yellow colour. About 38 per cent. is obtained from Virginian earth-nuts by the ordinary treatment, and nearly 10 per cent. more by a second hot-pressing.

The following table gives the results of the analyses of oil derived from various sources:—

	Oil from Virginian Nuts.	Oil from Spanish Nuts.	Oil from African Nuts.	Oil from Palm- cheri.	Com- mercial Oil.
Specific gravity at 15° C.	0.917	0.9175	0.911	0.920	0.9209

—A. S.

*Ceratin Industry, Notes on the.* B. Lach. Chem. Zeit. 1897, 21, [88], 916—917.

Among recent improvements, the introduction of an emulsifier is of special interest. This consists essentially of two flat plates revolving in opposite directions, and between which the hot ozokerite, mixed with the requisite quantity of acid, is introduced by means of a central opening in the axis of the upper plate. It is stated that a more thorough admixture can be effected in this way than by any other means, and that there is a considerable saving of acid and an accelerated output. Many attempts have been made to discard sulphuric acid altogether in the preparation of cerasin, but these have speedily been abandoned. By extracting the ozokerite with benzene after treatment with bleaching powder, lycopodium powder, and magnesium silicate, there is an increased yield (up to 96 per cent.), but the product is inferior, being greasy and often having an unpleasant smell. A method of increasing the yield, but little known, consists in adding to the ozokerite from 5 to 10 per cent. of a very heavy mineral oil. This gives a more wax-like character to the cerasin, but the addition is objectionable when a white product is required. Attempts to extract the filter-press residue in the filter-press itself, instead of in an extractor, have not given satisfactory results, owing to the following disadvantages:—Loss of solvent, tediousness, and danger of manipulation, and the necessity of having filter-presses of special construction.

The ukase forbidding the use of cerasin candles in the churches in Russia has been repealed, to the great advantage of the Russian cerasin industry. Austria has now to take a second place to Germany in the export trade in cerasin, owing largely to the Austrian Land Bank monopolising the sale of ozokerite and considerably raising its price.—C. A. M.

*Textiles, Soaps for.* Leipziger Färber- u. Zeugdr. Zeit. 46, [11], 491—492.

THE author discusses the different purposes for which soap is used, and points out that each process requires a soap specially adapted for the purpose; and hence a soap that may be excellent for, say, milling, might be unsuitable for printing or scouring. This difference in the behaviour of soaps is ascribed to the relative proportions of fatty acids and alkali therein. In a good, hard soap for printing purposes there should be 65 per cent. of fatty acids to 6 per cent. of soda; for dyeing purposes an olein soap, composed of 61 per cent. of fatty acids to 7.5 per cent. of soda, is recommended.

For silk-dyeing, a soap composed of 65 per cent. of fatty acids to 8 per cent. of soda should be used, some preferring nearly as much as 10 per cent. of soda; and for wool-scouring, a proportion of 61 per cent. of acids to 9 per cent. of soda. The same rules apply to soft soaps.—I. S.

## PATENTS.

*Oils, Crude: Impts. in the Method of and Apparatus for Brightening.* W. R. Harrison and E. Stephenson, both of Hull. Eng. Pat. 26,007, Nov. 18, 1896.

ESSENTIALLY, the process consists in breaking up the oil into minute particles either by passing it through a perforated coil or rose on to a revolving cone or cones, or by passing it through a screen or screens, or by means of a combination of these. Claim is also made for a special apparatus for thus aerating and brightening the oil.

—C. A. M.

*Soap, Dry, or Soap Powder: Impts. in the Manufacture and Production of.* W. W. Wright and The United Alkali Company, Ltd., Liverpool. Eng. Pat. 27,506, Dec. 7, 1896.

"ROASTER ASH" (crude sodium bicarbonate freed from ammonia) is mixed with ordinary soap and water, and the mixture dried by the addition of a further quantity of roaster ash. A good dry soap or soap powder is said to be produced by employing, for every 20 parts by weight of soap, from 60 to 65 parts of roaster ash and from 10 to 15 parts of water.—C. A. M.

*Soap, Resinous: Impts. in the Manufacture of, and Apparatus therefor.* F. Arledter, Perlen, near Luzern, Switzerland. Eng. Pat. 19,429, Aug. 23, 1897.

THE lather ascending in the resin boiler is subjected to the continuous action of a stirring apparatus fitted with cutting knives or planes, whilst the particles of resin ascending with the lather are melted by means of slotted hot metallic plates. The boiling process is thus shortened, owing to the expulsion of the generated gases, and a resinous soap is obtained containing a large quantity of liberated resin. Claim is also made for the employment of two varieties of apparatus in which this process may be carried out.

—C. A. M.

## XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

### (A.)—PIGMENTS, PAINTS.

*Painted Ironwork, Rusting of.* E. Simon. Dingler's Polytech. J. 1897, 305, 285.

IT is usually believed that the formation of rust on the surface of iron which is supposed to be protected by a layer of paint, is due to the passage of moisture and carbonic

acid through minute fissures in the oily covering, that owe their origin to the different rates of expansion under the influence of heat, possessed by the metal and the dried linseed oil. In order to test this point, the author has prepared a number of detached paint skins by coating gelatinised glass with different kinds of paint, and when dry stripping the films from the support after softening the gelatin substratum by immersion in cold water. After experiments with sea-water, &c., he finds that such skins, though absolutely free from distinct holes, are hygroscopic, and when swollen by damp, are readily permeated by water and gases.

Instead, therefore, of two coats of an oil paint forming a satisfactory protection for exposed ironwork, at least three or four coats should be applied; and, moreover, provided the material adheres well to the iron and possesses good covering power, that paint is the most efficacious which contains the highest percentage of varnish in its composition, and which accordingly allows the largest amount of oil to be applied to the unit of area.—F. H. L.

*Driers and Varnishes.* M. Weger. Chem. Rev. Fett- u. Harz-Ind. 4, [21], 285—289. (See also this Journal, 1897, 922—923.)

THE only effective driers hitherto discovered for increasing the siccativ properties of drying oils are all compounds of either lead or manganese, the calcium preparations sometimes sold for this purpose having no action beyond making the varnishes dry harder, whilst zinc salts merely improve the colour, and the value of copper compounds is confined to the prevention of rust and "fouling" on ships' bottoms.

From experiments made by the author, it appears to be practically immaterial—so far as the rate of drying is concerned—whether the driers of the older class or the so-called "soluble driers" are used, provided the quantity of metal dissolved by the oil is the same in either case.

The chief points of advantage offered by the use of the "soluble" driers are: prevention of sediment, lightness of colour, and reduced cost and danger of production, the three latter being due, it is said, to the lower temperature required in the preparation of the varnish.—C. S.

#### PATENT.

*Non-corrosive, Preserving, and Fire-resisting Paint, Improved.* "The Non-corrosive, Preserving, and Fire-resisting Paint Co., Ltd.," F. White, and J. Thomson, Christchurch, New Zealand. Eng. Pat. 23,294, Oct. 20, 1896.

As a fire-resisting composition for use on wood, 8 oz. of linseed oil are bodied up with sufficient flake white or other pigment to yield a paint of normal consistency, and with it are mixed sulphuric acid,  $\frac{1}{4}$  oz.; turpentine,  $\frac{1}{4}$  oz.; and ammonia,  $\frac{1}{4}$  oz. If the material is to be applied to ships' bottoms, &c., 1 dwt. each of chloride of copper, chloride of zinc, nitrate of mercury, and cyanide of potassium are also added.—F. H. L.

#### (B.)—RESINS, VARNISHES.

*Resins, Emulsion.* M. Bamberger and A. Landsiedl. Monatsh. für Chem. 1897, 18, 481—509.

THE resin from fir trees, treated in alcohol solution with caustic potash, yields a potassium derivative, from the aqueous solution of which acids precipitate a phenol-like substance, readily crystallisable, called by the authors *pinoresinol*, and having the formula  $C_{11}H_{14}O_2.(OC_2H_5)_2.(OH)_2$ . The diacetyl, dimethyl, and diethyl derivatives of this body were prepared. Nitric acid acts on pinoresinol, producing a body which crystallises from petroleum spirit in large golden-yellow crystals, which stain silk or the skin an intense yellow. From these crystals were prepared a potassium salt in red needles, a red barium salt, and an amide derivative. Analysis showed the nitro-compound to be dinitroguaiacol,  $C_6H_3(OH).OC_2H_5.(NO_2)_2$ . Bromine gives with pinoresinol the dibromide of a dibromide-derivative.

Pine-tree resin gives a pinoresinol identical with that from fir trees. Ether dissolves about 80 per cent. of the crude pine-resin; saponification shows this portion to

consist of the pinoresinol esters of abietic and paracumaric acids, the former in the greater proportion; and by the action of hydrochloric acid gas on the mixed ethereal solutions of pinoresinol and abietic acid, the soluble part of the pine-resin was artificially produced. The portion insoluble in ether has all the properties of a tannol: from it was isolated *pinoresinotannol*,  $C_{20}H_{30}O_6.(OC_2H_5)_2$ .

Larch-resin yielded a resinol similar in character to, but not identical with, pinoresinol; this *laricresinol* has the formula  $C_{11}H_{14}(OC_2H_5)_2(OH)_2$ . A triacetyl derivative was prepared by the authors, but the substance is still under investigation.—J. T. D.

*Varnish, "Unboiled" Linseed.* W. Lippert. Chem. Zeit. 1897, 21, 775.

THE author does not approve of H. Amsel's expression "unboiled" (this Journal, 1897, 924) as applied to varnishes made by dissolving metallic resins or linoleates in linseed oil, for the temperature necessary to effect solution is only some 70° or 80° lower than that required when the corresponding oxides are employed. The term is only suitable for such drying oils as are prepared (usually by the painter himself) by mixing raw linseed oil with a liquid drier, that is to say, with a ready-made solution of a resinate or a linoleate in oil of turpentine. When it is desired to differentiate between the two former varieties, instead of the words "boiled" and "unboiled," it will be better to speak of "oxide" and "resinate" varnishes respectively.

Objections to Amsel's "water reaction" have already been pointed out (this Journal, 1897, 702); Lippert now quotes further instances which go to prove its utter untrustworthiness. Amsel has also recently stated that when linseed oil is boiled without driers till it attains a syrup-like consistency, it loses its drying power. Products like this certainly do not dry so quickly as ordinary boiled oil, simply because they contain no lead or manganese; but they undoubtedly do dry, or they would not be used by painters, and they yield particularly elastic films.

Weger suggests (this Journal, 1897, 922—923) that the ready solubility of small quantities of certain compounds of manganese, e.g., the acetate and the borate, at comparatively low temperatures (120° C.) is due to the ease with which these bodies are decomposed by the free fatty acid of the oil into manganese linoleate and free acetic or boric acid. If this view be correct, as it probably is, the amount of metal capable of solution under the conditions referred to must be strictly dependent on the acid number of the oil; but it is invariably sufficient to convert the linseed oil into a quick-drying varnish. At higher temperatures (220° to 230°), however, a direct reaction or saponification takes place between the metallic oxides and the fatty glycerides; and the amount of metal dissolved is only limited by the proportion of fatty acid set free.

—F. H. L.

*Linseed Oil, Amsel's "Water Reaction" for, &c.* W. Lippert. Zeits. angew. Chem. 1897, [20], 653.

See under XXIII., page 1045.

#### PATENTS.

*Varnish [Copal], Impts. in the Manufacture of.* J. E. and C. S. Bedford, Leeds. Eng. Pat. 19,736, Aug. 27, 1897.

KARVI copal is rather difficult to dissolve either in linseed oil or in turpentine, and the usual practice hitherto has been to fuse the resin in order to increase its solubility. This process has the disadvantage of spoiling its colour, and of causing the formation of some brown products of decomposition. The inventors find that the fatty acids of linseed or castor oil are very efficient solvents; and to prepare a varnish suitable for floorcloth, they heat 200 lb. of the copal in a jacketed pan to 125° C. for four or six hours with 100 lb. of linseed acids, finally adding 700 lb. of turpentine, 150 of boiled oil, 200 of rosin spirit, and 100 of light petroleum.—F. H. L.

*Enamel, Patent-Leather Harness: Impts. in.* W. Walters and A. Webb, London. Eng. Pat. 20,202, Sept. 11, 1897.

This consists of asphaltum, 1 lb.; caoutchouc,  $\frac{1}{2}$  oz.; mineral naphtha, 1 oz.; and turpentine, 1 gallon. The varnish is applied to old patent-leather harness with a brush, in order to give it a brilliant polish equal to that of the material when new.—F. H. L.

*Nitrocellulose, Impts. in Treating for the Purpose of Coating or Impregnating Textile and other Fabrics.* D. M. Sutherland, Sunbury-on-Thames, and W. McLaren, London. Eng. Pat. 28,613, Sept. 14, 1897.

See under V., page 1013.

#### (C).—INDIA-RUBBER, &c.

*Sulphur Chloride, Analysis of.* G. A. Le Roy. Rev. de Chim. Indust. 1897, 8, [94], 294.

See under XXIII., page 1010.

#### PATENT.

*Rubber Compounds and Fabrics, Impts. in the Manufacture of.* F. H. Smith and C. Macintosh and Co., Manchester. Eng. Pat. 26,695, Nov. 25, 1896.

INDIA-RUBBER is incorporated with cellulose in a pulp form, and the mass is then rolled and pressed into any desired shape.

A compound fabric is made by spreading or impregnating cloth with the above material. Viscose (this Journal, 1893, 516) is, according to the patentees, the "form of cellulose" to which their invention is particularly applicable.

—H. I.

### XIV.—TANNING, LEATHER, GLUE, SIZE.

*Tan Liquors, Fermentation Phenomena in.* F. Andreasch. Imp. Research Laboratory, Vienna. Der Gerber, 23, [544], 111, [546], 135.

*The Behaviour of the Tannin.*—It has been shown, in the researches on the sources of carbon, that neither yeasts nor bacteria ferment the tannin. Some moulds, e.g., *Penicillium Glaneum*, decompose the tannin, and especially in those materials which contain only a small amount of non-tannin in comparison with their tannin (quebracho and knopperrn liquors and extracts).

This is because the acid-producing micro-organisms do not find in these materials sufficient suitable carbon compounds to enable them to compete with the moulds. The latter are able to utilise the carbon of the tannin after all the non-tannin is used up. The most favourable temperature, 25°–35° C., for the rapid fermentation of tannin by *Penicillium* is seldom met with in practice. The only other changes the tannin undergoes are oxidation phenomena brought about by the oxygen of the air. The most important of these in bark tannins is the formation of phlobaphenes. The precipitation of these bodies is hastened by the acidity of the liquors.

In an experiment to determine this action, sterile air was passed in equal quantities through three flasks, *a*, *b*, *c*, each containing 300 c.c. of pine-bark infusion: *b* received an addition of 2 grms. of acetic acid; *c*, 3 grms. of lactic acid. The tannin before the experiment was 0.2922 gm. per 100 c.c. After the passage of the air it was:—

In <i>a</i> .....	0.2137 gm. per 100 c.c.
" <i>b</i> .....	0.2000 " "
" <i>c</i> .....	0.1987 " "

All the flasks were free from germs, and the amount of non-tannin was unchanged. Pine, oak, and hemlock barks contain the most easily oxidisable tannins. This precipitation of tannin appears to be analogous to the destruction of the colouring matter of red wine exposed to air and light. The influence of the tannin on the micro-organisms is merely to render their action slower; it never arrests it while any fermentable substance is present; it even assists acetic bacteria by absorbing oxygen, which is an absolute necessity for these organisms.

The size of the cells of bacteria is smaller in tannin solutions than in those free from tannin, but yeasts and moulds are not affected, and no alteration either in the size or form of yeast cells can be detected.

In conclusion, a few of the more important results of the research may be briefly summarised.

1. Putrefactive bacteria from the hides, bates, &c., accommodate themselves to the acid reaction of tan liquors; they dissolve certain nitrogenous constituents of the hide, and thereby furnish the chief nutriment for the more specific acid-producing bacteria. In liquors which are in use, the production of acid is proportional to the hide substance present, provided sufficient quantity of carbohydrates are present.

2. Acetic acid, which in fresh tan liquors is the chief acid, is always formed by two separate processes: (1) the production of alcohol by yeasts from the glucoses of the non-tannins, and (2) the fermentation of the alcohol by acetic bacteria. In tan liquors it is never formed directly from carbohydrates.

3. Lactic acid is produced by several species of bacteria both from the sugars and other carbohydrates of tan liquors, and from the sugars alone by a yeast. A good supply of nitrogenous nutriment is necessary for its production, the greater part of which is furnished by the hides.

4. Butyric acid occurs in traces only in sound tan liquors.

A practical application of the results, is the preparation of sour liquors from materials poor in fermentable matter, by addition of glucose and alcoholic yeasts, or by direct addition of alcohol, which is quickly changed to acetic acid. A proper lactic fermentation is best induced by the sowing of the lactic yeast in the liquors.

The behaviour of the tannins has just been considered, and need not be repeated.

If the acids produced in the liquors by these various fermentations have not the same importance for the tanner as formerly, yet the fermentations and decompositions themselves are of great importance, and a more exact knowledge of them is certainly of interest for him. The author gives the above work as a contribution to a better knowledge of these processes.—J. T. W.

*Leather Dressing.* Der Gerber, 1897, 109, 121, 147, 159, 171, 175, 207.

In greasing leather with mixtures of dégras and tallow, it is frequently found that the same mixture is applied with but varying success to different batches of hide. Especially is this known to occur when the mixture is applied in a warm state to the skins. This frequently arises from the mixture having been insufficiently stirred during cooling, so that the solid fats crystallise out; or in the properly made mixture having been again heated above its melting point before application, and allowed to cool slowly on the leather. In this case the mixture is no longer homogeneous, but consists of a liquid oily portion and crystalline aggregates of palmitin and stearin. It is therefore obvious that, particularly as regards the tallow, the best article to use is not the kind generally quoted as the best, i.e., the fatty acids of which melt at about 48° C., but the medium and lower qualities. Great care is also required in the selection of the seal or fish oil, the most oxidisable brands of which are by no means the most suitable for the production of dégras, since they are liable to suffer from over-oxidation and then only yield a very poor quality of dégras, containing large proportions of pitchy matter instead of the valuable "moëllon." It is, however, erroneous to ascribe the specific action of dégras exclusively to the "moëllon" (surplus oils removed from softened skins by expression) contained in it. But, on the other hand, the remarkable property of "moëllon" in uniting so firmly with the tanned animal fibre as to be no longer removed from it by any of the solvents of grease, appears to be almost unknown. Oxidised (blown) seal or fish oils, which are extensively offered as dégras substitutes, behave very differently from the real article, which they only resemble in their property of emulsifying with water. On examination under the microscope, it is, however, readily seen that the globules of water in the blown oil emulsion are at least ten times the size of those in the

dégras. The greatest fault of these blown oils is their liability to "spue," and form a resinous coating on the surface of the leather. On the other hand, they possess, nevertheless, the distinct advantage of a greater initial consistency than dégras, and consequently they can be used with a smaller admixture of tallow. Another constituent of all dégras of commerce is wool grease, which, especially in its purified neutral form, is very well suited for the purpose of dressing leather, not by itself, but in admixture with either the seal or fish oils, or with dégras. With particular advantage it is employed to replace, either partly or entirely, the tallow in the grease mixtures used in dressing leather. For practical purposes a distinction is made between light and heavy fish oils, and of the two, the former are the less suitable. Of the heavy fish oils, those are the most valuable for the tanners' use which contain least of palmitin. The colour of these oils is comparatively unimportant. Also mineral greases are employed in the dressing of leather. They act in a particular way, and besides being used to regulate the properties of the other greases, they chiefly serve the purpose of imparting additional weight to the leather. The light mineral oils are generally used in dressing mixtures and dégras to render the harder greases present more liquid. Solid mineral greases are frequently used as tallow substitutes, over which they possess the advantage of not being crystallisable. Rosin oil has acquired an ill repute amongst tanners, although there is no doubt that it can be employed to very great advantage.

—C. O. W.

#### *Catechu.* Textile Colorist, 1897, 19, 298.

THERE are principally four kinds of catechu, distinguished in commerce according to their origin, viz.:—

1. *Bombay catechu*, which is the dried extract from the heart-wood and fruits of *Acacia catechu*. It occurs in large irregular lumps of dark brown colour, which have a glossy fracture, and are nearly completely soluble in hot water.

2. *Bengal catechu*, from the unripe pods of *Acacia* and *Mimosa catechu*. It is of a somewhat brighter colour and less soluble than Bombay catechu. Both kinds are imported from India, Java, Pegu, and Singapore.

3. *Gambier catechu*, ordinarily termed "gambier," is the extract from *Uncaria Gambier*. The commercial article occurs in cubes, covered with rush mats, and soft inside. It is imported from Batavia and Singapore, and is earthy and porous, having a dull fracture.

4. *Kino*, which is a product of *Pterocarpus marsupium*, has a dark red-brown colour and very glossy fracture.

All varieties of catechu are only slightly soluble in cold water, but almost completely soluble in hot water. With gelatin or sulphuric acid they give brown precipitates: with salts of iron, green ones. Starch, sand, clay, and blood are common adulterations. Good catechu should not give more than 5 per cent. of ash, nor contain more than 12 per cent. of substance insoluble in boiling alcohol.—I. S.

*Sodium Sulphide used in Leather Dressing.* Note on the Analysis of the. F. Jean. Ann. de Chim. Anal. 2, [18, 341; Analyst, 1897, [260], 306.

See under XXIII., page 1041.

*Sunae.* Adulteration of. W. Eitner. Der Gerber, 1897, 33, 161.

See under XXIII., page 1044.

#### PATENTS.

*Tanning of Hides, Skins, and the like; Impts. in and connected with.* J. Y. McQuinn, Runcorn, and E. Caldwell, Warrington. Eng. Pat. 23,742, Oct. 26, 1896.

IN the process described, hides and the like are immersed, after depilation and cleansing, in a bath of dilute sulphuric acid for from three to five minutes, according to the strength of the bath, and the thickness and nature of the material to be tanned. For ordinary hides the bath is made up of 2 vols. of rectified sulphuric acid to 8 vols. of water. The hides being now rolled or otherwise partially

dried, are placed in a tanning bath composed of or containing an alkaline bichromate, canella, aloes, and sulphuric acid in water, in which they remain for from less than half an hour to over six hours. This completes the tanning. The pits must be constructed of such material as stone or concrete. The object of the invention is economy of labour and the obtaining of results in less time than at present.

—J. G. P.

*Tanning of Hides and Skins, Improved Means to be used in the.* E. J. Thibaut, London. Eng. Pat. 18,332, Aug. 6, 1897.

HIDES and skins are suspended apart from each other, and so maintained within a drum provided with liquid-tight doors for introducing and removing. The drum contains the tanning agent, and is slowly rotated. The suspension and rotation are so related that during each rotation the hides are completely dipped into and withdrawn from the tanning liquid. The drum is mounted on standards, and one of its journals is hollow, and arranged so as to admit the tanning agent into the drum, the other journal being fitted with gear so as to secure relatively slow rotation. Means are provided for running off the tanning agent.—J. G. P.

*Tanning of Hides and Skins, Improved Means to be used in the.* E. J. Thibaut, London. Eng. Pat. 20,354, Sept. 4, 1897.

THIS invention differs from that above described (Eng. Pat. 18,332), in that the hides, though suspended within a drum, are not stretched. They are so suspended that, in the course of the rotation of the drum, they roll and rub in contact with each other; and while being raised from out of the tanning liquid and carried over, are separated and straightened out. The drum is here cylindrical, but essentially the same as that described in the preceding abstract.

—J. G. P.

*Casein Glue, Liquid; Impts. in.* H. Bolder, Charlottenburg. Eng. Pat. 19,661, Aug. 26, 1897.

TO prepare this glue, 100 parts of dry casein are treated with a solution of two parts of borax to from 60 to 80 parts of water, the mixture being then heated nearly to boiling, kept at this temperature for about half an hour, and constantly stirred. Instead of borax solution, a solution of ammonia may be used, such that it will give a slight alkaline reaction. Starch may be added.—J. G. P.

*Tanning Hides and Skins, An Improved Process for.* J. Mossop, jun., and E. B. Garland, both of Cape Town. Eng. Pat. 20,125, Sept. 1, 1897.

THIS is a process of drum-tanning. For cleansing, after the usual treatment with lime, the hides are subjected, in a rotating drum, to the action of carbonic acid gas under pressure. After cleansing, the hides are placed in a rotating drum, containing a strong tanning liquor, and are kept rotating in the atmosphere of carbonic acid gas, either under pressure or not, until tanning is completed; this being effected in from 2 to 30 hours.—J. G. P.

*Tanning of Hides, Skins, and the like, for the Production of Leather; Impts. in the, and in the Apparatus employed therein.* E. H. Dewson, Massachusetts, U.S.A. Eng. Pat. 21,601, Sept. 21, 1897.

THIS is a method of drum-tanning. The drum has a number of compartments, and these are arranged around its axis of rotation. Each compartment is complete in itself, liquor-tight, and independent, with its own charging hole and cover, and carrying its own load of hides and liquor. The hides are always immersed in the liquor, and the drum always substantially in balance.—J. G. P.

#### XV.—MANURES, Etc.

*Potato Scab, Prevention of, by Means of Formalin.* Bulletin of the Agricult. Stat. of the Purdue University; through Nature, 1897, 56, (1456), 502.

EXPERIMENTS conducted with "seed" potatoes at the Agricultural Station of the Purdue University show that

formalin will practically free infected tubers from scab. The method employed is to soak the tubers for two hours in a solution of formalin of the proximate strength of 1:300, made by adding half a pint of "formalin" to 15 galls of water. This solution is found to be as effective for the purpose as the dangerous and more troublesome solution of mercuric chloride. Seed material of apparently good quality, as well as that much affected with scab, benefited by this treatment. The same formalin solution may be used several times for successive lots of "seed" tubers.

## XVI.—SUGAR, STARCH, GUM. Etc.

*Sugar, Diffusion Juice, Conditions for obtaining Dense.* B. Mittelmann. Bull. de l'Assoc. des Chim. 1897, **15**, [3], 205—208.

Although all are agreed as to the principle of the production of a diffusion juice of high density, the limit to which the exhaustion of beetroot pulp should be carried, is strongly contested. Karlson maintains that diffusion should be arrested as soon as a product is obtained not capable of furnishing crystallisable sugar, for, assuming the non-sugar in massecuite from such juice to be equally melassigenic with that in molasses, any further exhaustion would give a useless increase of uncrystallisable products and a diminution in the yield of crystalline sugar; the exhaustion should therefore not be pushed beyond 60 or 50, or, as an extreme limit, 40 degrees of purity. When the sugar recovered, however, is obtained free of duty, it will be difficult to resolve to abandon it, although in the form of molasses.

The best temperature for diffusion is always the lowest, as giving a juice of a higher degree of purity. A temperature of 70° C. gives excellent results with rich beetroots, but with those of lower quality, either the temperature must be raised to 75° or 78° C., or, preferably, a longer time of contact must be allowed, by increasing the number of diffusers to 14 or 16. This gives a juice at least one degree purer. It is very advantageous to wash with hot juice, so that the juice leaves at 30° to 35° C. The pulp undergoes a more thorough diffusion, the juice obtained is denser, and the purity is not inferior to that obtained by cold mashing. To secure uniform exhaustion of the pulp, a layer of water 20 to 30 cm. deep is introduced into the diffuser before filling with fresh pulp, and cross pipes at each third of the height are arranged to cause the pulp to distribute itself uniformly.—L. J. de W.

*Invert Sugar, Formation of, during Diffusion.* H. Pellet. Bull. de l'Assoc. des Chim. 1897, **15**, [3], 208.

When the quantity of reducing sugars in beetroot juice, obtained by rasping and pressing in the cold, is compared with that in diffusion juice, no increase is found during ordinary work, but rather a tendency to a diminution thereof. When a stoppage occurs in the diffusion process, reducing bodies are found in proportion to the length of time work is at a standstill, the principal effect being observed in the first diffusers, which have not been subjected to the higher temperature of the rest of the battery. That Claassen finds an increase of 0.10 per cent. of reducing bodies is attributed to the fact that he used a different method of analysis for the fresh pulp and the diffusion juice.—L. J. de W.

*Washing Beetroots.* Bull. de l'Assoc. des Chim. 1897, **15**, [3], 197—204.

*Absorption of Water or Loss of Sugar in the Hydraulic Conveyors and Washers.*—According to arrangement

between grower and manufacturer, it is usual to add to the tare, 1 per cent. or 2 per cent., to allow for water absorbed and mechanically retained by the beetroots after washing; but as the operation of taring a sample, usually of 20 kilos., occupies less time than that of conveying and washing the beetroots on the large scale, Pellet has studied the question afresh.

The duration of contact of water and beetroots in the conveyor is relatively short. The speed of the water is 125 to 130 metres per minute, and in many installations the conduits do not exceed 150 to 250 metres in length, and as roots are thrown in throughout the greater part of this length, the average contact is much reduced. Fairly clean beetroots were plunged in water for about two minutes, then drained and weighed. The increase was 0.80 to 0.90 per cent. After wiping completely, the water absorbed was found to be only 0.10 to 0.30 per cent., or 0.60 to 0.70 per cent. of water mechanically retained. Even with a-naphthol, only traces of sugar were found in the water.

Allowing half an hour of contact between the water and the beetroots from their entry into the conveyor to the removal of the washed beets for weighing, it was found that 0.60 to 0.80 per cent. of water was absorbed and 0.20 to 0.25 mechanically retained, and the loss of sugar was 0.020 to 0.035 per cent.

A very sensible difference may thus be found between the richness of the beetroot trimmed and cleared in the laboratory and that of fresh beetroot slices. The latter will contain 0.6 per cent. of earth, 1 per cent. of water absorbed, 1 per cent. of tops containing 7 per cent. of sugar, leaving 97.4 of beetroot at, say, 13 per cent. of sugar, giving a total of 12.72. From this, 0.03 is to be deducted for loss of sugar in the washers. Thus, instead of 13 per cent. found in the laboratory, we should find only 12.69 per cent.

Mittelmann finds that the sugar lost in the wash water is insignificant, but when beetroots are touched with frost, and warm water must be used to loosen the adhering earth, the injured beetroots may lose 0.10 to 0.60 per cent. of sugar.

The average time occupied by beetroots passing through the washers in a factory observed by Gubal was 45 minutes. He therefore immersed carefully cleaned beetroots in water and examined a portion every 15 minutes for an hour. The rate of absorption of water was greatest during the first half-hour. In 45 minutes the water absorbed was 0.433 kilo. per 100 kilos. of beetroots, the sugar lost 0.101 kilo.—L. J. de W.

*Beetroot, Reducing Sugars of.* H. Pellet. Bull. de l'Assoc. des Chim. 1897, **15**, [3], 233—236.

On heating to 85° C. for a quarter of an hour, 100 c.c. of a mixture of 50 c.c. of Fehling or Violette's solution and 50 c.c. of a solution of sugar containing no glucose, there is no reduction, but if only a few decigrams of invert sugar be present, the whole of the corresponding copper is reduced. If the mixture contain reducing bodies other than glucose (invert sugar), the liquid filtered after heating to 85° C. and again heated on the water-bath for half an hour to an hour, gives increasing quantities of oxide of copper. It is possible in this way to estimate 0.08 to 0.09 of invert sugar in 100 grms. of molasses, and afterwards 0.70 to 0.80 of reducing bodies which have not at all the characters of invert sugar. Tested thus, the reducing bodies contained in beetroot and cane juice, show very great analogy with invert sugar, so that there is every reason to admit that they are identical with it.—L. J. de W.

*Sugar Seams, Filtration and Washing of.* Mittelmann. Bull. Assoc. Chim. 1897, **15**, [3], 223—224.

The froth which forms at the commencement of carbonating is nothing but hydro-sucrocarbonate of lime, and instead of using grease or steam as a preventive, the author proposes an excess of carbonic acid, which would immediately decompose this compound.

There are numerous causes which retard the filtration and washing of seams. Cholesterin, isolated by Herzfeld from a sample of seam and originally attributed to the

beetroot, but afterwards found to arise from the grease or oil used to prevent frothing,—even when present in very small quantity, may completely arrest filtration, owing to its property of undergoing a considerable increase in volume. When the juice is overheated during diffusion, pectin is formed, and this unites with iron contained in the lime to produce a flocculent and spongy mass of ferropectin, which obstructs the filter cloths.

Overburnt lime hydrates slowly, and is apt to leave unslaked particles, which, after carbonating, form sucrate of lime; the juice then filters with difficulty. With unripe or frozen beetroots, difficult filtration is avoided by working at a temperature of 70° or 72° C., or even lower, increasing the lime used, and carbonating rapidly with gas of 30 per cent., and heating afterwards to 90° C. Water of condensation often contains ammonium carbonate, and calcareous water contains bicarbonate of lime; these, when used for washing the scum, precipitate carbonate of lime in the pores of the filter cloths, obstructing them. The author prefers water from the triple effect for washing scums, as it precipitates nothing from the juice.—L. J. de W.

*Molasses and Peat Fodder in Germany.* J. Soc. Arts, 1897, [2343], 1149.

THE use of molasses as a food for cattle and sheep has, during the past few years, been largely experimented on by agriculturists in Germany. The chief objection to the use of molasses is the purging effect which it exercises on cattle; but this, it is claimed, has been overcome by the admixture of a dust or mull obtained from moss-turf (peat). The moss-turf—from which the dust is obtained by means of a machine such as is used for making moss litter—is taken from the upper strata of high-lying peat moors, and consists largely of the dried but decomposed fibre of the *Sphagnum cuspidatum* and the *Eriophorum latifolium*. The action of the dust or mull appears to be one counteracting the severe purging caused by the molasses alone. It is recommended that the molasses peat-fodder, which is 50 per cent. cheaper than the best fat-producing food and yet equal in nourishment, should first be given in very small quantities, and the amount gradually increased.—A. S.

*Sugar, On the Speed of Reduction of Ferric Alum by.* J. H. Long. J. Amer. Chem. Soc. 1897, 19, 683.

See under XXIV., page 1052.

*Sugar, Alleged Formation of Humin from, by Oxidation with Potassium Permanganate.* H. v. Feilitzen and B. Tollens. Ber. 30, [17], 2581—2584.

BENNI (Dissertation, Giessen, 1896; Zeits. für Naturwissenschaften, 69), assuming that the formation of humin is due to an oxidation process, has sought to obtain this substance from sugar by means of permanganate. The authors, after investigating the matter, state that the brown precipitate produced by the oxidation of sugar with permanganate, consists mainly of manganese oxide and potash, and that no actual formation of humin takes place.—A. S.

*Yeast found in the Sugar Juices of Refineries.* Wochenschrift für Brau. 1897, 14, 602—603.

THIS yeast (*Saccharomyces Zopfii*) was found by Zopf in beetroot juices together with *Leuconostoc Mesenteroides*. It is a small yeast, which forms spores like beer and wine yeasts. It can resist a moist heat of 67° C., and when dry, a temperature of 130°—135° C. It inverts cane sugar, and at high temperatures appears to secrete a peptonising ferment. Only cane sugar and glucose are readily fermented by it. Besides alcohol and carbonic acid, the products of fermentation include an organic acid, which was extracted by ether, but was not sufficient in quantity to be identified.

—A. L. S.

*Starch, Products of the Saccharification of, by Diastase.* P. Petit. Comptes Rend. 1897, 125, [6], 355—257.

STARCH is treated, at 70° C., with 1 per cent. of diastase, until, in about half an hour, a constant red coloration is given with iodine. The liquid is fermented by means of yeast, and the substance obtained, after purification with

alcohol and ether, possesses a constant rotatory and reducing power, and a molecular weight of 428 is assigned to it, and the formula  $(C_6H_{10}O_5)_3$ . This dextrin is a white non-hygroscopic body, and is not capable of yielding osazones. When treated with boiling dilute hydrochloric acid, it is completely converted into glucose after three hours, but if the reaction be arrested after half an hour, and the product treated with phenylhydrazine and sodium acetate, two osazones are obtained, one being glucosazone and the other corresponding to a member of the cane-sugar group. It appears, therefore, that the dextrin yields on inversion at first glucose and a "diose," and the latter on further boiling furnishes two molecules of glucose.

*Further Action of Diastase.*—On further treatment at 50°—55° C. with 1 per cent. of diastase, the dextrin yields two substances, and by comparison of their respective rotatory and reducing power with that of the solution containing both, the author calculates that the yield of one substance is twice that of the other. The change occurring is therefore represented by the equation—

—R. B. B.

*Starches, Chemistry of the.* C. J. Lintner. Chem. Zeit. 1897, 21, 737—738 and 752—754.

THE author has extended his previous researches (this Journal, 1894, 53) on the starches. A short account of the chemical nature of the dextrins is first given.

*Isolation of the Dextrins.*—The isolation of the dextrins has been greatly facilitated by the application of the cryoscopic and osazone tests, and the purity of a product may now be fairly determined by having recourse to these, together with polarisation, reduction, and iodine-reaction tests. Aqueous alcohol has, after many trials, proved itself the best medium for the isolation and separation of the dextrins. Alcoholic baryta and alcoholic milk of lime possess the disadvantage of tending to decompose them; moreover, when any considerable quantity of material is to be operated upon, as is always the case in such experiments, the use of these reagents is not admissible. The solubility of a dextrin is commonly the greater, the lower the molecular weight of the compound; but there is an unusually great mutual influence between them in this respect when they exist together in solution. Hence, it is necessary to pay great attention to the strength of the alcohol and to the concentration in each individual case. Greater dilution must be employed towards the end of the fractionation. Much depends upon the manner in which this process is conducted. If, finally, strong alcohol be added to the aqueous solution of the dextrin, the result is always far more unsatisfactory than if the hot dextrin solution, mixed with alcohol, be poured, with brisk agitation, into the hot alcohol of known quantity and strength, and the whole be then allowed to cool to the temperature of the room.—W. G. M.

*Soluble Starch.* A. Wroblewski. Ber. 1897, 30, [14], 2108—2110.

THE authors restrict the term "soluble starch" to the first decomposition product of starch, which gives a pure blue coloration with iodine and does not reduce Fehling's solution. Amylodextrin is a decomposition product of soluble starch; iodine colours it reddish-brown, and it somewhat reduces Fehling's solution.

The best method for preparing soluble starch is as follows:—Triturate 100 grms. of the best rice starch with small quantities of 1 per cent. caustic potash solution and let stand 2—4 hours; repeat this process until the whole has attained a volume of 600—800 c.c. Heat on the water-bath with constant shaking until the jelly-like mass has become perfectly fluid, boil over the naked flame for 20—30 minutes, filter, add acetic acid to feeble acid reaction, precipitate with an equal volume of 95 per cent. alcohol, again dissolve, and precipitate. Finally dissolve in a little water, pour in a thin stream with violent stirring into a large volume of absolute alcohol, wash with absolute alcohol and ether, and dry *in vacuo*. The resulting snow-white substance contains very little ash, gives a pure blue with iodine, does not reduce Fehling's solution, and is soluble in water to

the extent of 4 per cent. The neutralisation by acetic acid is to facilitate washing only; the alkali is not combined with the starch, its action being merely catalytic.

Soluble starch is obtained by the first hydrolysis of starch, effected also by the action of diastase, acids, and water, but with these reagents, hydrolysis proceeds further. By long boiling with dilute potash, a substance is obtained with a very feeble reducing action on Fehling's solution.

—A. C. W.

*Soluble Starch.* W. Syniewski. Ber. 1897, 30, [16], 2415—2418.

COMPARE Wroblewski (previous abstract). The author's method for preparing soluble starch is as follows.—Add 50 grms. of commercial sodium peroxide in small quantities at a time to 500 grms. of well-cooled water, bring into this solution 50 grms. of potato starch rubbed up with 500 grms. of water. In an hour, add alcohol of 95 per cent., dissolve the precipitated mass in cold water, and neutralise the cooled solution with acetic acid; again precipitate, dissolve, and acidify. On repeating this process several times, a substance is obtained containing only traces of ash. From the aqueous solution, on standing, a small yellow flocculent deposit separates, leaving a completely clear liquid. From this, the starch is precipitated by alcohol; it is then ground with alcohol, washed on a filter with anhydrous ether, and dried by warming *in vacuo*. The product was a snow-white amorphous body without taste or smell, giving, on analysis, figures corresponding with the formula  $C_6H_{10}O_5 \cdot H_2O$ . It is soluble in cold water; solutions stronger than 12.5 per cent. could not be obtained at the ordinary temperature, but it appears to be soluble in hot water in every proportion. It gives a pure blue coloration with iodine, which property is not changed by prolonged heating on the water-bath, and it does not reduce Fehling's solution. At 20°, the specific rotation,  $[\alpha]_D$ , is  $182^\circ.66$  for 2.5 per cent. solutions, and increases to  $189^\circ.5$  at 12.5 per cent. strength. This increase in optical rotation with increasing concentration, it is alleged, accounts for the divergent results obtained by Nägeli, Brown and Morris, &c.

The yield of soluble starch obtained by the author's method is almost quantitative (90 per cent.), and the loss is due to purely mechanical causes.—A. C. W.

*Mould [Starch, Dextrin, Maltose, &c.], A New: "Europtipsis Gayoni."* J. Laborde. Ann. Inst. Pasteur, 1897, 1—43.

THIS mould was first observed by the author on starch paste, where it resembled a growth of *Bacillus Prodigiosus*; however, when examined microscopically, it was seen to be a red mycelium.

This mould will grow on any of the media which commonly are used for growing moulds. It acts on starch, dextrin, and maltose, converting them into glucose. Invert sugar it destroys partly by fermentation and partly by oxidation, the glucose being acted on the more quickly.

Cane sugar and inulin need to be first inverted before the mould can act on them; it can, however, hydrolyse lactose.

Ethyl alcohol (6—8 per cent.) is oxidised by the mould to carbonic acid and water; methyl alcohol can also be decomposed, but propyl, butyl, and amyl alcohol are poisonous to it.—A. L. S.

## XVII.—BREWING, WINES, SPIRITS, Etc.

*Wort and Beer, Determination of the Solid Matter of, and the Relation between this and the Specific Gravity.* C. N. Riber. Videnskabselskabets Skifter. 1 Mathematisk-naturv. Klasse, 1897, No. 5.

(See this Journal, 1896, 756.) The author has already attacked this question, and he came to the conclusion that the results depended on the pressure and temperature at which the drying took place, something similar to dissociation occurring. He, however, has now found that if the temperature be below 80° C., the same constant result will be arrived at, however the drying be effected.

The tables in common use on the Continent for determining the extract of wort and beer are those of Balling and Schultz-Ostermann; Balling's table is based on the strength of cane-sugar solutions, and, of course, is well known not to give the true extract for worts; and as the alteration of volume on dilution is different for malt worts and cane-sugar solutions, the error between these tables varies for different strengths of solution. Schultz-Ostermann's table was obtained by direct determination of the solid matter contained in worts, but the author finds it to be about 5 per cent. too high.

When the solid matter was dried until constant at different temperatures below 80° C. and under various pressures, the same results were obtained, but at 100° decomposition took place and different results were obtained. The drying took two days at 80°; 80 days at ordinary pressure and ordinary temperatures, or 25°; and 10 days under reduced pressure at 50°.

As a result of the experiments on the relation between the specific gravity of worts and beer extracts and the solid matter contained in them, it was found that there was a certain relation between them. This is illustrated by the following example:—A wort of sp. gr. 1.04143 contained 10 per cent. of solid matter; a beer residue of the same sp. gr. contained 9.930 per cent. of solid matter; the ratio between these figures is 1.0100. This ratio the author calls the "quotient." If these two are now concentrated to a sp. gr. of 1.060, and the wort is found to contain 14.262 per cent. of extract, then the beer residue will contain  $14.262 \div 1.010 = 14.119$  per cent. of extract. It thus follows that if a table be prepared for some particular wort or beer residue, then, if the quotients are determined for other varieties of worts or beer residues, the table may be used for determining the extracts of these worts or beer residues.

The author has determined the value of this quotient as affected by the following conditions:—The amount of nitrogen. The composition of the brewing water. The boiling of the wort. The fermentation of the wort. The variation of the kilning temperatures. The different brewing methods (decoction or infusion). The addition of the hops.

The variation of the nitrogen percentages within the usual limits does not have any appreciable effects.

The variation in the composition of the water does, however, have a considerable effect, and the author's results are given in the following tables.

The Munich water contained 26 parts per 100,000 of solid matter, chiefly calcium carbonate. The Copenhagen water contained 34 parts per 100,000, chiefly calcium sulphate. The first artificial water contained 50 parts of calcium carbonate; and second, 50 parts of gypsum per 100,000.

The "quotient" is the extract as found by experiment, divided by the extract as found by the table.

For a fully fermented beer the quotient is 0.990; that is, a beer residue contains 1 per cent. less solid matter than a wort of the same specific gravity.

The kilning temperature, the brewing method (decoction or infusion), or the amount of hops, have no appreciable effect on the quotient.

The author has prepared a series of tables giving the amount of solid matter contained in worts, &c. of different specific gravities; but as this may be derived from the Schultz-Ostermann table by multiplying by 0.9181, it is unnecessary to reprint it here.

assuming the network form, constitute the third class, and give albuminoid reactions. Finally, there is a "crystalline network," consisting of needles of different sizes, and partly of dendritic or fascicular agglomerations of plates. Their nature is as yet undetermined; they are insoluble in hydrochloric acid and concentrated acetic acid, though soluble in nitric acid, highly resistant towards concentrated sulphuric acid, and indifferent towards iodine and aniline dyes.—C. S.

**Acetic Acid Bacteria, Contribution to the Physiology and Morphology of the.** W. Seifert. Centr. Bl. f. Bakt. und Parasitk. 11. 1897, 3, [13—14], 337; Zeits. für das ges. Brauw. 20, [40], 517—518.

COMPARATIVE experiments were made on the oxidising action of *Bacterium Pasteurianum* and *B. Kützingerium* (with, in some cases, *B. aceti* Hansen and a species probably identical with *B. xylinum* Brown) on various alcohols and sugars. The nutrient medium generally employed was a decoction of yeast, admixed with the substances under examination; and the temperature of the experiments ranged from 26° to 30° C.

Ethyl- and propyl alcohol were converted by both bacteria into acetic and propionic acid respectively. Butyl- and isobutyl alcohol were also found capable of oxidation, under conditions favouring the development of the organisms; but neither methyl- nor isopropyl alcohol was attacked. On amyl alcohol, *B. Pasteurianum* had no effect, and the action of *B. Kützingerium* remains undetermined.

Ethylene glycol is oxidised to glycollic acid, which restricts the development of the bacteria. Both the last-named organisms exert a much smaller influence on glycerin than does *B. aceti* Brown. Mannite is acted upon only by *B. Kützingerium*, its conversion into levulose being effected less energetically than by *B. aceti* Brown and *B. aceti*

Hansen. *B. xylinum* alone oxidises sorbite into sorbose. Glucose is converted into gluconic acid, *B. Kützingerium* producing the greater effect; the acid restricts both organisms. No change is produced by either in levulose, maltose, propionic acid, or butyric acid, and all are inert towards dulcitol. Both readily consume acetic acid.

The author considers it probable that with a more favourable medium, the influence of the organisms might be greater in some of the instances where negative or only slight results were obtained. In any case the conclusion is permissible that the fermentative power of the acetic acid bacteria on monovalent primary alcohols varies inversely with the carbon content of the latter; and also that *B. Pasteurianum* is the weakest of the organisms examined, so far as their effect on the polyvalent alcohols and glucose is concerned.—C. S.

**Glycerin in Wine from Grapes affected by Sweet-rot, "Pourriture Noble."** J. Laborde. Rev. de Viticulture, 1897, May 8 and Sept. 18; La Bière, 5, [10], 151—151.

The ratio of glycerin to fermented sugar in wines prepared from grapes which have been allowed, according to the practice current in Saunterne and other districts, to become infected with *Botrytis cinerea*, has been found by the author to range between 4.1 and 11.6 per cent., i.e., considerably higher than in ordinary red and white wines (3.5 per cent.).

The fungus in question causes the grapes to lose moisture, but as its action is gradual and does not come into play on all the grapes in a vineyard at the same time, there result three classes of grapes termed respectively *verts* (unaffected by *Botrytis*); *pleinourris* (slightly affected); and *rôtis* (more or less desiccated). That the influence of the *Botrytis* also induces chemical changes in the fruit, is shown by the subjoined analytical data (1895 grapes):—

Class of Sample.	Density.	Must.			Wine.			
		Acidity per Litre.	Sugar per Litre.	Residual Sugar per Litre.	Alcohol per Cent. by Vol.	Glycerin per Litre.	Ratios of Glycerin to Fermented Sugar per Cent.	
		Grms.	Grms.	Grms.	C.c.	Grms.	Grms.	
(Grapes) Verts.....	{ No. 1.....	1.095	2.55	230	0	13.2	7.68	3.3
	{ No. 2.....	1.090	2.70	220	0	12.6	7.16	3.2
" Pleins pourris.....	{ No. 1.....	1.115	2.72	263	0	15.5	17.45	6.6
	{ No. 2.....	1.096	2.94	230	0	13.5	11.52	5.0
" Rôtis.....	{ No. 1.....	1.170	4.31	345	260	10.6	27.50	14.9
	{ No. 2.....	1.137	4.40	339	140	11.2	25.60	12.8

from which it appears that the amount of glycerin increases simultaneously with the progress of the infection. Similar results were obtained with 1896 grapes, and with wines of 1893 vintage. The quantity of alcohol formed, appears to vary inversely with that of the glycerin produced, and though this variation in alcohol content may be in part due—as Gayon has shown—to the retarding influence exerted on the yeast by the presence of high percentages of sugar, still the results obtained are considered to justify the assumption that the development of *Botrytis* has a similar effect in restricting the formation of alcohol.—C. S.

**Diastase, Chemical Constitution of, and the Occurrence of an Arabin in Diastase Preparations.** A. Wroblewski. Ber. 1897, 2289.

DIASTASE was prepared from finely ground malt by first treating it with 68 per cent. alcohol, and then twice with 45 per cent. alcohol. Alcohol was then added to the extract until it attained a strength equivalent to 70 per cent., and the precipitate was purified by solution in 15 per cent. and reprecipitation by 70 per cent. alcohol; and then by re-solution and precipitation with magnesium sulphate. This was dissolved and dialysed until free from sulphuric acid, and finally precipitated by strong alcohol and ether.

The white preparation thus obtained was almost completely soluble in water, gave no coloration with iodine, but all the albuminoid reactions, with the exception of the biuret

reaction. It did not reduce Fehling's solution. It agreed in composition and properties with the descriptions of diastase by other writers. When boiled with dilute acids it gave a precipitate which yielded the albuminoid reactions, the filtrate reducing Fehling's solution.

To determine if this preparation was a mixture, Brücke-Kulze's method was employed. The solution of the diastase was treated with mercury-potassium iodide and dilute hydrochloric acid; a voluminous precipitate was thrown down, which was found to contain an albuminoid. The solution gave a precipitate with alcohol, which was found to be a dextrin-like carbohydrate.

The albuminoid was freed from the metals thrown down with it; it was then only partially soluble in water, but was able to transform soluble starch into sugar.

The carbohydrate did not reduce Fehling's solution, and was levo-rotatory. When boiled with dilute acids it yielded arabinose. It thus appears that the substance, previously described as diastase, is a mixture of a carbohydrate with an albuminoid, of which the latter only is the active body. This contains 15.3—16.2 per cent. of nitrogen.—A. L. S.

**Barley, The Germination of, with Restricted Moisture.** T. Cuthbert Day. Trans. and Proc. Bot. Soc. Edinburgh, 1896, 492—501.

The author's experiments were carried out with three varieties of barley, viz., Hungarians, Scotch Chevalier, and Ordinary Smyrna. The degree of moisture for germination

was estimated by determining the moisture in one portion of the barley, then taking the weight of 100 selected corns and steeping them in distilled water at 57° F. for 24, 48, 72, or 96 hours. At the end of the steeping period the corns were externally dried and weighed. The amount of the soluble matter in the steep water, added to the increase of weight in the corns, gave the total quantity of water absorbed; the absolute amount was found by adding the original moisture present in the sample. The steeped barley was then placed in a small flask immersed in water at 57° F., the apparatus being so arranged that a current of air saturated with aqueous vapour at 57° F., from which carbon dioxide had been removed, could be aspirated. The air in passing through the apparatus could thus take no moisture from the germinating grain, neither could the corns extract any moisture from the air supplied to it.

The aspirated air was dried and passed through weighed potash bulbs. Germination lasted from 12 to 16 days; the corns were then taken out of the flask and weighed, the embryos excised from the endosperms and husks, and the moisture determined in each by drying at 100° in a current of dry air at reduced pressure. A large number of experiments were carried out under the above conditions, and the results shown graphically in curves.

With regard to the quantity of carbon dioxide exhaled, it appears that an increase of moisture always produces a corresponding increase in the amount of this gas. Moreover, when the moisture is considerably increased, it was found that during the first day or two of germination, the quantity of carbon dioxide excreted is little less than for lower degrees of moisture, but the grain soon recovers its partial drowning, and increased activity due to increase of moisture, asserts itself.

The dry weight of the embryo of a corn germinated for 14 days, after a 96 hours' steep, gave a value more than double that obtained when the steep was only 24 hours.

When the number representing the increase in the dry weight of the embryo during germination is divided by the weight of carbon dioxide exhaled, it was found that the product increases in value as the quantity of moisture used in germination is increased. It thus appears that with the larger quantities of moisture, the embryo increases more in weight for the same amount of carbon dioxide exhaled, than it does when less moisture is present.

The percentage of moisture found in the embryo at the end of the germinative period was generally nearly double of that found in the endosperms, the disparity being always greater the smaller the quantity of moisture employed in the experiment. The results of the moisture determinations seem to show that the new forming tissue cannot grow with any degree of success unless it contains above 63 per cent. of water.

Considering the production of carbon dioxide as a measure of growth during germination, it was found that the period of greatest activity, with varying quantities of moisture, generally occurred about the third or fourth day, the period being to some extent delayed with increase of water. After the point of greatest activity is reached there is a gradual fall in vitality to the end of the germinating period.—J. L. B.

## PATENTS.

*Seasoning or "Curing" Casks, Improved Process of, and Apparatus therefor.* J. Gillies. Eng. Pat. 29,899, Dec. 29, 1896.

The casks are cured by steam and heated air or hot products of the combustion of carbonaceous matter, with or without the addition of sulphurous gases. The admission is controlled by a plug-valve so constructed that it may be rotated in its casing to connect the parts with steam and air pipes. An injector is formed on or secured to it, enabling air to be drawn in and mixed with the steam.

—J. L. B.

*Ale, Pale; Impts. in or relating to the Manufacture of.* A. Fraser, Alloa, Scotland, and Maclay and Co., Limited, Alloa, Scotland. Eng. Pat. 15,200, June 25, 1897.

The patentees claim the use of oat malt as one of the ingredients used in the preparation of pale ale: the combination of oat malt with sugar, hops, and water, and oat malt with barley malt for brewing purposes. It is noted that oats in the process of malting require to be steeped for 45 hours, as compared with 72 hours for barley.

—J. L. B.

*Ageing Whiskey and other Alcoholic Liquors, An Improved Process and Apparatus for.* D. J. Etly and C. R. Long, Louisville, Kentucky, U.S. Eng. Pat. 18,713, Aug. 12, 1897.

The lower end of a funnel-shaped tube, closed at the bottom and filled with water, is placed within the barrel containing the alcoholic liquid; the temperature being raised and maintained by means of steam. When the heating has been continued sufficiently long, steam is shut off and salt introduced into the tube to form a strong brine. A refrigerating material, such as gaseous ammonia, is forced through pipes contained in the tube until a low temperature is reached. This alternate heating and cooling is continued for varying periods—according to the character of the alcoholic liquid—until the desired flavour and aroma are obtained. An apparatus enabling several barrels of liquid to be treated simultaneously is also described.—J. L. B.

## XVIII.—FOODS; SANITATION, WATER PURIFICATION, & DISINFECTANTS.

### (A).—FOODS.

*Food Products, Antiseptics in.* F. Jean. Rev. de Chim. Ind. 1897, 8, [94], 289—293.

ALTHOUGH the use of antiseptics is entirely forbidden in France, the author states that the authorities are often very lax in enforcing the law, and cites an instance in which the vendor of borated butter was acquitted in one court and fined in another. This laxity, together with contradictory judgments, have produced uncertainty among traders as to what is permissible, and have encouraged the sale of antiseptics and preserved articles of food. Thus, hams preserved with borax are largely imported into France from England and America, and, according to Prof. Carles, of Bordeaux, immense quantities of fluorides are being sold under various names in that part of the country. In addition to the more common antiseptics, the author states that fluosilicates and fluoborates are employed, and he has even found fluosilicic acid in butter. With regard to the ill-effects of preserving agents in general, he takes boric acid as the type, and quotes the toxic effects ascribed by Mitscherlich to that substance. According to le Féré, borax is only eliminated from the system very slowly, and has been detected in the urine 40 or 50 days after it had been taken.—C. A. M.

*Milk, Preservation of, by Partial Freezing.* F. Jean. Rev. Chim. Ind. 1897, 8, [93], 267—268.

ACCORDING to G. Quesneville, the pasteurisation of milk is often employed to conceal various forms of adulteration, noticeably the removal of cream, since skimmed milk when heated on the water-bath assumes the appearance of whole

milk. Now that the Casse process has proved successful on a commercial scale, he considers that it should take the place of sterilising by heat, which alters the character of the milk. In the early part of 1896 the Casse Company established two milk depots at 160—170 kilometres from Copenhagen, for freezing milk, and a third depot in Copenhagen for defrosting and distributing it. In the three depôts, 30,000 litres of milk can be treated each day at a cost of about  $\frac{1}{2}$  centime per litre. In ordinary weather,  $\frac{1}{2}$  to  $\frac{3}{4}$  of the total milk is frozen; in very hot weather,  $\frac{1}{2}$  to  $\frac{3}{4}$ . After being frozen, the milk, in blocks of about 12 kilos., is placed in isolated vessels, which next day are filled up with fresh milk and despatched to Copenhagen.

As an experiment, 300 litres thus partially frozen were sent from Copenhagen to Paris, when it was found, after defrosting, that the milk was perfectly normal in character and of excellent quality.—C. A. M.

**Milk, Occurrence of Alcohol in.** H. Weller. *Analyst*, 1897, [259], 261; *Forsch. Ber.* 1897, 4, 206.

KÖNIG (Nahr. und Genusmittel, 1893, 249) stated that when cattle are fed upon fodder containing alcohol, the latter does not pass into the milk. The author, however, obtained the following results on examining a milk derived from a number of cows which were fed on distillery slumage containing 5.9 per cent. of alcohol:—Specific gravity of milk, 1.0335; fat, 3.89 per cent.; total solids, 13.307 per cent.; and alcohol (by weight), 0.96 per cent.—A. S.

**Coffee, Raw; Amount of Water in.** B. Niederstadt. *Forsch. Ber.* 1897, 4, 111.

With the object of determining the average percentage of water in raw coffee as put upon the market, the author examined samples of several different kinds. These were dried to constant weight at 105°C., and gave the following results:—Santos I., 13.33; Santos II., 12.20; Santos III., 11.23; Santos IV., 14.50; Bahia, 8.54; Menado, 10.72; Java, 10.75; Columbia, 10.00; Costa Rica, 10.62; Guatemala, 10.18; and Santos V., 9.45; the mean being about 11 per cent.—C. A. M.

**Coffee, Alterations produced in, on Roasting.** A. Jucke-nack and A. Hilger. *Forsch. Ber.* 1897, 4, 119—135.

THE authors have studied the alterations which take place when coffee is roasted in the usual manner, and with the addition of 8 or 9 per cent. of sugar as specified in a German patent. The chief results of their experiments are:—

1. **Caffeine.**—In the ordinary process of roasting, coffee loses about 21 per cent. of its caffeine, and about twice that quantity when roasted with sugar, owing to the higher temperature which is required to caramelize the sugar, so as to glaze the coffee.

2. **Fat.**—From 9 to 10 per cent. is lost during the ordinary process of roasting, and about 20 per cent. in the glazing process. As a rule the different constants of the fat show an increase on roasting by either method.

3. **Organic Matter.**—In the authors' experiments the loss on the average amounted to 11.375 per cent. in the ordinary roasting, whilst in the glazing process it was about 10 per cent., allowance being made for the amount of caramel. This was determined by Stutzer's method. 20 grms. of the glazed beans were shaken in a machine for five minutes with 500 grms. of water at 20°C. The liquid was filtered, and the residue in 250 c.c. of the filtrate, after deducting the ash, was taken as caramel. In this way, on coffee glazed with 9 per cent. of sugar, there was found 1.40 per cent. of caramel, as against 1.25 per cent. on a sample of Java coffee glazed with 8 per cent. of sugar. (This *Journal*, 1897, 473.)—C. A. M.

**Foods, Vegetable; Amounts of Ash and Iron in certain.** B. Niederstadt. *Forsch. Ber.* 1897, 4, 140.

THIS paper gives the figures recently obtained by the author in his analyses of various vegetable products used as food. The amount of iron as  $\text{Fe}_2\text{O}_3$  in 26 samples of American apple cuttings, varied from 0.009 to 0.046, but as

these had all been cut with a steel knife, it was possible that part of the iron might have been derived from the knife. The mean percentage of ash in the specimens of apple examined was 2.5, and the iron oxide ranged from 0.25 to 0.94 per cent. In unroasted coffee berries of various origin, Liebig found from 0.019 to 0.044 per cent. of iron oxide, whereas the author's analysis of 17 samples gave, as a rule, considerably higher results, the raw berries containing from 0.35 to 0.88 per cent., and the roasted berries from 0.07 to 0.65 per cent.—C. A. M.

**Milk, Formalin in; Detection of, by Means of Phloroglucinol.** Jorisson. *Bull. Soc. Chim.* 1897, 167; *Analyst*, 1897, 260, 282.

See under XXIII., page 1045.

## PATENTS.

**Preserving Organic Bodies, Impts. in Apparatus for.** L. A. M. D. de Belfort. *Paris. Eng. Pat.* 14,307, June 19, 1897.

See under I., page 1005.

**Coffee, Impts. in the Treatment of.** S. Feitler, Ludwigshafen, Germany. *Eng. Pat.* 19,815, Aug. 28, 1897.

THE coffee is treated, before or after roasting, with gelatin and resinous substances, such as gum, benzoin, shellac, stick lac, &c. The pores of the beans are thus hermetically closed, enabling the aroma to be preserved for a long period.—J. L. B.

## (B).—SANITATION; WATER PURIFICATION.

**Disinfection of Houses.** F. W. Alexander. *Public Health Engineer*, 1, 543—544 and 557—559.

THE replies received to a circular letter sent round to the chief sanitary authorities of this country, asking for information upon certain points in the disinfection of houses and clothing, showed that there is a lack of uniformity in the processes now in use, but that disinfection by means of sulphur fumigation is the most usual method.

As the experiments carried out by Drs. Koch, Wolffhügel, Hüppe, and Proskauer proved this mode of disinfecting rooms to be most unsatisfactory and unreliable, the author investigated the relative powers of other disinfectants, *viz.*, corrosive sublimate, formic aldehyde, para-formic aldehyde, and quinosol ("Chinosol"). From the results obtained in these investigations, the following suggestions are made:—

1. That disinfection of rooms by means of sulphur gas should cease, as its efficiency to kill all germs appears to be more than doubtful.

2. That the walls, floors, and ceilings of rooms should be sprayed with a formalin (formic aldehyde) solution, 1 in 80, or with a solution of quinosol, 1 in 1,000.

The benefits accruing from adopting the above method (2) may be summarised:—

1. The disinfectant may be applied immediately to the floors, walls, and ceilings.

2. The disinfectant used is not harmful, either to the men carrying out the work, or to the occupants of the rooms, should it eventually, after becoming dry, float into the air as dust.

3. The disinfectant in solution is of sufficient strength to kill all germs.

4. The necessity of sealing up the rooms for hours would be abolished, and the tenants would practically occupy the rooms almost immediately after the spraying process had been concluded.

5. The spraying process may be carried out in the time taken for sealing up the rooms in the sulphur process.

6. The process is much cheaper than sulphur fumigation. A number of rules are also added for the guidance of the men carrying out the disinfecting work, and relate to the wearing and disinfecting of the overalls worn and the washing out and fumigation of the vans employed for the collection and delivery of articles.—W. P. S.

### PATENTS.

*Filter for Sewage Effluent and the like, An Improved.* C. Fell, Hanley, Staffordshire. Eng. Pat. 22,768, Oct. 14, 1896.

THE crude sewage, just before flowing into the precipitation tanks, is made to pass through perforated zinc boxes containing chloride of lime; and the effluent from the tanks is made to pass through similar finely-perforated boxes also containing chloride of lime.—L. A.

*Sewage Sludge, Improved Process for Treating.* B. Walker, Hawes, Yorkshire. Eng. Pat. 24,833, Nov. 6, 1896.

A SMALL quantity of peat, intimately mixed with sewage sludge, makes the latter much more porous and combustible. Even 0.5 per cent. of peat dust greatly facilitates the filtration and pressing, but a larger quantity, 1 of dry peat to 7 of water in the sludge, is preferable. The pressed cake may be broken up, mixed with more sludge and re-pressed several times, and will burn by itself in a furnace, or even in the open air, if the fire be started with dried cake or other fuel, especially if grease or soap be contained in the sewage.

When iron precipitants are used, the ash consists largely of magnetic oxide of iron, and is an excellent filtering medium. The filter is constructed of furnace clinker, broken and sifted into various sizes, and arranged in layers. The calcined sewage sludge forms the top layer which, when choked, is shovelled off, pressed, and re-calcined. The filter is kept aerated by means of air-pipes communicating with the various layers.—L. A.

*Filtering Apparatus [Water], Impts. in and relating to.* H. H. Lake, 45, Southampton Buildings, London, W.C. From "La Société Ch. Prevot et Cie," Paris. Eng. Pat. 25,710, Nov. 14, 1896.

THE filter consists of two shells of unsized paper, which are connected at their edges, and enclose a lens of perforated metal, or of porous material such as carbon. The liquid passes through the filter from the exterior to the interior, the lens being formed with, or serving as, a chamber for the reception of the filtered liquid, and being fitted with a delivery nozzle, &c. The filter thus constructed, forms a portable or pocket filter, suitable for use by soldiers, sportsmen, &c., but a number of filtering elements may be combined in a single apparatus, several arrangements of such combinations being described in the specification.

—R. A.

*Drains, Improved Means for Testing and Disinfecting.* C. T. Kingzett, Chislehurst, Kent. Eng. Pat. 28,090, Dec. 8, 1896.

ANY suitable material which emits smell or smoke on simple exposure, or on being wetted, or a disinfectant, is contained in a small metallic cylinder open at one end, and so inserted open end uppermost, into a larger cylinder containing a spring, or having an elastic band stretched over its mouth, that when flushing takes place by means of water, the spring or elastic diaphragm is released, causing the inner case to be forced out and the material liberated.

—L. A.

*Garbage, and the Recovery of Ammonia therefrom; Method and Furnace for the Incineration of so-called.* J. F. G. de Bonardi, Marquis du Ménéil, Paris. Eng. Pat. 29,009, Dec. 17, 1896.

REFUSE matter, such as city garbage, after separation of incombustible substances and of powder directly applicable as a manure, is charged through hoppers provided with

valves so constructed as to exclude free passage of air, into a distilling chamber constituting the upper part of the furnace. The refuse is carried forward on trays by endless chains to the front of the furnace, where the bottom of the chamber slopes downward, and is provided with valved apertures, through which the charred refuse descends, passing into the incinerating chamber, whence the ash is delivered into a closed ash pit. The incinerating chamber is supplied with air, in such quantity, that whilst ensuring combustion, excess of oxygen is avoided, and the reducing gases resulting are led through a series of chambers in which the greater part of the heat is withdrawn for utilisation, so that they may pass into the distilling chamber at a temperature not exceeding 650° C., the temperature of the incinerating chamber varying between 1,000° and 1,500° C. The gaseous products of distillation are withdrawn by a fan into ammonia-absorbing apparatus.—E. S.

*Sewage, Impts. in and relating to Material for Use in the Treatment and Purification of, and other Impure Waters.* W. B. Bottomley, London. Eng. Pat. 29,288, Dec. 21, 1896.

NATIVE aluminous and ferruginous calcium phosphate is ground, and treated with sulphuric or hydrochloric acid, in sufficient proportion to form soluble aluminium and iron salts with the phosphate. The mixture is used in precipitating sewage, from 8 to 10 grains per gallon of sewage being recommended in ordinary cases.—E. S.

*Sewage and the like, Impts. in or relating to the Filtration of.* J. Guthrie, Hawick, Roxburghshire, N.B. Eng. Pat. 18,974, Aug. 17, 1897.

THE invention is a mechanical device for automatically controlling the operation of two or more filters working in rotation. As each filter becomes full of liquid, a float rises which, by tilting the inlet trough, diverts the influent to another filter, and at the same time opens a valve which discharges the first filter.—L. A.

### (C.)—DISINFECTANTS.

#### PATENT.

*Formic Aldehyde Vapours, Impts. in the Production of.* G. B. Ellis, London. From La Société Chimique des Usines du Rhône, formerly Gilliard P. Monnet et Cartier, Lyons, France. Eng. Pat. 27,656, Dec. 4, 1896.

THE method claimed consists in mixing a solid polymer of formic aldehyde (for instance, trioxymethylene) with water and then heating the mixture to 130°–135° C. in an autoclave capable of resisting a pressure of 5–6 atmospheres. It is found preferable to mix 100 parts of the solid polymer with 40 parts of sea salt (or other normal salt) and to press this mixture into cakes, for convenience in transport.

—W. P. S.

## XIX.—PAPER, PASTEBOARD, Etc.

*Observations [and Analytical Methods used] in the case of some of the Chemical Substances in the Trunks of Trees.* F. H. Storer. Bull. Bassey Inst. 1897, 2, 386.

See under XXIII., page 1019.

*Filter Papers, The Reaction of.* L. Magnier de la Source. Rev. Intern. falsific. 10, 163; Chem. Centr. 1897, 2, [17], 909.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

*Oxygen, Industrial Preparation of.* Dutremblay and Lagan. J. Pharm. et de Chim. 1897, 6, [9], 392–396.

TESTÉ du Motay's well-known manganate process is carried out best under a slight pressure, it is said, and so that th

entry of air or furnace gases is impossible. The oxygen is forced to the gas-holder by the steam pressure, thus avoiding impurities arising from a lubricated pump. The purifier consists of a horizontal cylinder, divided by screens carrying the purifying mixture over which the air passes. The furnace consists of a generator, combustion chamber, and two heating chambers, each containing ten vertical retorts. These retorts are connected with systems of pipes for leading in air and steam, and for conveying away nitrogen or oxygen. The distribution of the gas, to or from the retorts, is effected by ten counterpoised valves worked by compressed air. A distributor, worked electrically, sends the compressed air to the piston moving each valve. The gas-holder is provided with a condenser. Up to the present, two serious defects have prevented the success of the Tessie du Motay process—the settling of the mixture and the evaporation of the soda. The use of horizontal retorts with a thin layer of manganate in small lumps had avoided the first defect, but this disposition of the material led to the formation of channels. The patents of Lawson (1890), Bowmann (1891), Parkinson (1891), Fanta (1891), Webb (1892), &c., endeavoured to overcome the settling by the use of various admixtures with the manganate. The authors have found the solution of the problem “in mechanical arrangements applicable to vertical retorts.”

The compressor is of the compound type, the pistons lubricated by an injection of water, which is extracted from the gas before it reaches the cylinders, by passage through a refrigerator. A furnace containing 20 vertical retorts, 140 mm. in diameter and 2·4 m. high, will make in 24 hours 100 c.m. of oxygen free from carbon, and containing 94–96 per cent. of pure oxygen.—A. C. W.

**Cerium.** O. Boudouard. *Comptes Rend.* 1897, **125**, [20], 772–774.

Cerium sulphate, free from thorium, was precipitated by lead acetate and excess of lead removed as sulphide. In the cerium acetate solution on standing, a precipitate formed, which was converted into the sulphate, and the sulphate was analysed by ignition. The atomic weight  $Ce = 137·85$  was deduced from the results of this process. In the same way, the recrystallised sulphate gave  $Ce = 137·35$ , and the salt obtained from the mother liquors  $Ce = 135·1$ . The mother liquors of the basic acetate were separated into four fractions; these gave figures ranging from 136·05 to 139·1.

Hydrogen peroxide partially precipitates cerium from solutions of its acetate; the precipitated oxide was converted into sulphate and this salt fractionally crystallised. The fractions gave atomic weights between 137·15 and 137·6. The cerium precipitated as oxalate from the residual hydrogen peroxide liquor, gave results from 137·85 to 139·9.

Cerium sulphate was fractionally precipitated by potassium sulphate. From the fractions results ranging between 133·0 and 138·75 were obtained. The author concludes that oxide of cerium is accompanied by small quantities of the oxide of a metal of lower atomic weight, which metal can form a dioxide and an insoluble double sulphate with potassium sulphate.—A. C. W.

**Silver, Colloidal.** A. Lottermoser and E. von Meyer. *J. Prakt. Chem.* 1897, **56**, [17–18], 241–247.

Few quantitative observations on the conversion of colloidal into common silver have been made. The use of “soluble silver” as an ointment in septic diseases gave surprising effects; and it was found that the silver passed into the fluids of the body, in spite of the fact that they all contain small quantities of sodium chloride, which ordinarily precipitates silver from the aqueous colloid solution. This behaviour was explained by the discovery that albumin partially or wholly prevents the precipitation of colloidal silver by sodium or hydrogen chlorides.

The conversion of silver from the colloidal to the insoluble form was observed by the following titration method:—5 c.c. of a 0·5 per cent. aqueous solution of colloidal silver was diluted with a known volume of water, and standardised solution of an acid or salt was run in from a burette. At one point a sharp change from the original

coffee-brown colour to green could be detected, but the completion of precipitation was proved when a drop of the liquid brought on filter paper appeared colourless, except for the fine particles of silver present. The colloidal solution used, was free from insoluble silver, but contained traces of ammonium citrate. With regard to acids, it was found that the quantity needed to precipitate the colloidal silver was inversely proportional to the co-efficient of affinity of the acid, but that it increased with the degree of dilution of the silver solution, and decreased with a prolongation of the time allowed for the reaction. The following gives the volume (in c.c.) of normal solutions of certain acids, which precipitates the silver from 25 c.c. of 0·1 per cent. colloidal solution:—formic 4·75, monochloroacetic 0·93, trichloroacetic 0·25, cyanoacetic 0·8, oxalic 1·2, malonic 2·41, succinic 16·25, and tartaric 3·75. The volume for  $\frac{1}{2}$ N. sulphuric acid is 2·13 c.c.

The action of salts on the silver solution varies according to their nature. Small quantities of the alkali salts of acids which form silver salts soluble with difficulty, precipitate the silver, but alkali salts of acids which form readily-soluble silver salts do not throw down all the silver in the insoluble form, even when present in much larger amount. Very small quantities of salts of the heavy and earth metals effect the change. The halogens readily convert colloidal silver into salts, which also behave as colloids; thus when 3 per cent. alcoholic solution of iodine is added to dilute colloidal silver, a milky and yellowish-white liquid results. The whole of the silver iodide, however, is thrown down by a small addition of mineral acid.

Colloidal silver is a very feeble conductor of the electric current, which, however, causes a migration of the particles. Grey, spongy silver accumulates at the cathode; and at the anode there collects a brown mud of silver only, which yields a green aqueous solution. When dried in the exsiccator this modification changes to golden-yellow, and is insoluble in water.—J. A. B.

**Sodium Iodide.** J. C. Umney. *Pharm. J.* 1897, **59**, [1424], 312.

See under XXIV., page 1651.

**Protargol [Albumin containing Silver].** *Note on.* O. Loew. *Chem. Zeit.* **21**, [84], 876.

PROTARGOL is the name given by Eichengrün to a compound of albumin containing silver, in which the silver (8·3 per cent.) is present, not as a salt, but in molecular combination. The compound, on account of its bactericidal action, has found application in therapeutics. Loew states that he prepared such compounds in 1883, by the continued heating of albumin with ammoniacal silver solution. The silver, which can neither be precipitated by sulphuretted hydrogen nor hydrochloric acid, varies in amount with the quantity of silver nitrate used. Addition of caustic potash causes a marked enrichment in silver, and preparations containing from 32 to 82 per cent. of silver may be obtained.

—J. T. C.

**Chloroform, Bromoform, and Chloral; Decomposition of, by Aqueous Potash.** A. Desgrez. *Comptes Rend.* 1897, **125**, [20], 780–782.

ALUMINOTIC potash decomposes chloroform to form potassium chloride and formate. Frenier has shown that at temperatures below 30° C., traces of formate are produced, but chiefly carbon oxychloride, and a little hydrogen. The author finds that chloroform is decomposed by aqueous potash in the cold, with the production of carbon monoxide.  $CHCl_3 + KOH = KCl + 2HCl + CO$ . This is the principal reaction when 10 grms. of chloroform, 400 grms. of water, and 50 grms. of potash are mixed. Light accelerates the reaction. Bromoform is decomposed more slowly by reason of its lower solubility; insoluble iodoform shows no decomposition. Chloral is more rapidly decomposed than chloroform, the heat generated by its first decomposition accelerating the second. Ammonia and the alkaline bicarbonates do not produce this reaction, but André has shown that it takes place with water alone, in sealed tubes at 200°–225°.—A. C. W.

*Anæsthetic Aqueous Solution of Tertiary Trichlorobutyl Alcohol*]. A new Anæsthetic. Apoth. Zeit. 1897, 12, 608.

A new synthetic body has been introduced, which is stated to be an aqueous solution of tertiary trichlorobutyl alcohol, having marked anæsthetic and hypnotic properties.

—J. O. B.

*Strophanthus Seeds, Adulteration of.* P. Siedler. Ber. Pharm. Ges. 1897, 7, 222.

STROPHANTHUS seeds are often adulterated with those of the African plant *Kicksia Africana*. With the aid of a simple lens they can be distinguished, the *Kicksia* seeds being smooth, spiral, or S-shape, not flat, and with base and tip about equally pointed, while the *Strophanthus* seeds always show traces of hairs, are flatter, rounded at the base and sharp at the tip. The cross section shows the cotyledons much folded in the *Kicksia* seeds, but parallel in the others. Treated with strong sulphuric acid, the cross section of the *Kicksia* seeds turns first brown, then red, whilst that of the *Strophanthus* seeds turns green.—J. T. D.

*Pine Oils, American.* Semi-Annual Report of Schimmel and Co., Oct. 1897, 47.

*Oil of Fir Needles.*—Distilled from the leaves of *Pinus sylvestris*, this oil had a sp. gr. of 0.884, and a rotation of  $-24^{\circ} 8'$ . This levo-rotation is noteworthy, since it agrees with that of the English distilled oil; the German and Swedish oil is dextrogyrate. The American oil contained bornyl acetate, which, from the acid number, 34.8, is present to the extent of 12.1 per cent. The oil was soluble in 8 vols. and more of 90 per cent. alcohol.

*Oil of Hemlock Needles.*—Distilled from the leaves of *Abies canadensis*, the specific gravity was 0.911 and the rotation  $-25^{\circ} 22'$ , at  $16^{\circ} \text{C}$ . The oil contains 38 per cent. of bornyl acetate, and is soluble in one or more parts of 90 per cent. alcohol.

*Oil of Spruce.*—Distilled from needles of *Picea nigra*. The specific gravity was 0.930 and the rotation  $-23^{\circ} 50'$ , at  $18^{\circ} \text{C}$ . The oil contained 31.8 per cent. of bornyl acetate, and was soluble in  $\frac{1}{2}$  vol. of 90 per cent. alcohol; on further addition of  $4\frac{1}{2}$  vols. the solution becomes opalescent.—J. O. B.

*Larch Needle Oil.* Semi-Annual Report of Schimmel and Co., Oct. 1897, 61.

THE needles of *Larix europæa* yielded only 0.22 per cent. of oil on distillation. This had the sp. gr. 0.878, and was dextrogyrate  $+0^{\circ} 22'$ , at  $18^{\circ} \text{C}$ . It was soluble in 90 per cent. alcohol, and its acid number was 23.3, which, after acetylation, was increased to 46.

Presnning the ester of larch oil to be bornyl acetate, as is the case with most coniferous essential oils, the first figures would indicate 8.9 per cent. of bornyl acetate, equivalent to 6.5 per cent. of combined borneol, while the latter figures indicate 6.14 per cent. of free borneol; the total borneol being therefore 12.76 per cent.

Submitted to fractional distillation, the following results were obtained:—

From  $160^{\circ}$  to  $165^{\circ} \text{C}$ , 30 per cent.; from  $165^{\circ}$  to  $170^{\circ} \text{C}$ , 24 per cent.; from  $170^{\circ}$  to  $180^{\circ} \text{C}$ , 16 per cent.; from  $180^{\circ}$  to  $190^{\circ} \text{C}$ , 8 per cent.; from  $190^{\circ}$  to  $200^{\circ} \text{C}$ , 4 per cent.; from  $200^{\circ}$  to  $230^{\circ} \text{C}$ , 9 per cent. Residue, 9 per cent.

The oil had a pleasant larch needle fragrance; the small yield and the difficulty in obtaining large quantities of raw material are, however, drawbacks to its considerable commercial use.—J. O. B.

*Star Anise, Cultivation of, in China, and Method of Distilling the Oil from.* "Decennial Reports, 1882 to 1891, of Trade, &c., of the Ports open to Foreign Commerce in China and Corea." Published by order of Inspector-General of Customs, Shanghai, 1893; through Semi-Annual Report of Schimmel and Co., Oct. 1897, 57.

THE Lungchow star anise is considered better than that produced in the Po-sé district, and yields more oil. The trees, originally wild, but now frequently cultivated, grow on hill sides, where the sloping ground prevents water from standing around the roots, yet retains enough moisture

as the rain runs down from the higher ground above. The trees are very liable to injury from smoke, and as the common habit in clearing fields is to burn the grass and debris, the neighbourhood of villages is avoided in selecting a place to plant, and the dry grass beneath the trees is cut and carried off yearly to prevent the spread of accidental fires. Young trees bear fruit suitable for commercial purposes after 10 years, and trees 100 years old still bear. The yield of the same tree varies much from year to year, and trees that produce every year are rare. They flower at the beginning of February, and the anise fruit is gathered in August and September. Fresh anise fruit is worth ordinarily 5.50 dols. per picul.

The oil is extracted from fresh anise fruit by distillation. Steam passes through a wooden cylinder containing the anise, placed over the boiler, into an earthenware jar, where it is condensed by cold water placed in a pan on the top. The condensed mixture of water and oil flows through a pipe into a tin-lined box of two compartments, in the partition between which is a hole near the top. The oil floating on the top of the water is drawn off through this hole into the other compartment. The process takes several days.

Fresh anise fruit yields 3 per cent. of oil, and a picul of oil is worth from 180 dols. to 190 dols. For transport it is packed in tins of 32 to 35 catties weight, and sent overland to Hong Kong.—J. O. B.

*Cardamom Oil (from Various Species of Cardamoms).* Semi-Annual Report of Schimmel and Co., Oct. 1897, 10.

*Oil of Malabar Cardamoms.*—The fruits of *Elettaria cardamomum* gave 2.14 per cent. of light yellow oil closely resembling in odour the commercial oil derived from Ceylon cardamoms. The specific gravity was 0.943, and optical rotation  $+34^{\circ} 25'$  at  $19^{\circ} \text{C}$ . It was soluble in four or more volumes of 70 per cent. alcohol. The saponification factor (acid number) was 132, indicating a high percentage of ester. The acid constituent of this ester was found to be acetic acid. On fractional distillation, cineol and a small amount of an optically active terpeneol were obtained. The latter was strongly dextrogyrate, the figure being  $+83^{\circ} 31'$  at  $21^{\circ} \text{C}$ . It further differed from the terpeneol of cajaput, which is optically inactive, in giving a nitrochloride melting at  $151^{\circ}$ – $152^{\circ} \text{C}$ . instead of  $159^{\circ}$ – $160^{\circ} \text{C}$ ., the melting point of that compound from inactive terpeneol.

*Oil of Siam Cardamoms.*—The fruits of *Amomum cardamomum*, which occasionally appear in the London drug market, where, from their camphoraceous odour, they are known as "camphor seeds," yielded 2.4 per cent. of oil, which was semi-solid at ordinary temperatures, liquefying at  $42^{\circ} \text{C}$ ., when it had a specific gravity of 0.905 and a rotation of  $+38^{\circ} 4'$ . The odour of camphor or borneol was very marked in this oil. Its saponification factor (acid number) was 18.8. On acetylation, this was increased to 77.2, corresponding to the presence of 22.5 per cent. of borneol. By centrifugation, the stearoptene was eliminated, and subsequently separated by crystallisation from petroleum spirit into dextrogyrate borneol and dextrogyrate camphor in approximately equal proportions.

*Oil of Cameroon Cardamoms.*—The fruits from which this oil was distilled were identical with those of Madagascar cardamoms, and are derived from *Amomum daniellii*. The yield was 2.33 per cent. The specific gravity was 0.907, and the rotation  $-20^{\circ} 4'$ . The odour is similar to that of cineol, which body was detected in the oil by the iodol reaction.

*Oil of Grains of Paradise.*—The seeds of *Amomum melegueta* gave 0.75 per cent. of oil, which had a specific gravity of 0.894 and a rotation  $-3^{\circ} 58'$ , and was soluble in 10 to 11 volumes of 90 per cent. alcohol.—J. O. B.

*Harmine and Harmaline.*—III. O. Fischer. Ber. 1897, 30, [16], 2481–2489.

THE earlier researches (Ber. 18, 400; and 22, 637) on the alkaloids obtained from the seeds of *Peganum harmala* had shown that harmaline,  $\text{C}_{13}\text{H}_{14}\text{N}_2\text{O}$ , is dihydroharmine, and that both alkaloids gave on oxidation the base  $\text{C}_8\text{H}_8\text{N}_2$ , apoharmine. Harmine and harmaline are optically inactive. The former may be obtained from the latter by oxidation

with nitric acid, or better, potassium permanganate in acid solution. Both alkaloids form addition compounds with methyl iodide, which, decomposed by alkali, yield methyl harmine and methyl harmaline. The tertiary bases so obtained combine with methyl iodide. From the harmine compound, dimethylharmine was obtained.

By reduction of harmaline by sodium in amyl alcohol solution, dihydroharmaline (tetrahydroharmine) is formed. This substance, as also dihydro-apoharmine, had already been shown to be a secondary base. Harmine acid is obtained by the oxidation of harmine or harmaline with chromic acid in acetic acid solution. Methylharmine acid,  $C_{10}H_{12}N_2O_4(CH_3)$ , is produced by the oxidation of methylharmine, or by the methylation of harmine acid.

Apharmine,  $C_8H_8N_2$ , yields the nitro compound  $C_8H_7N_2(NO_2)$  by the action of concentrated nitric acid, and methylapoharmine,  $C_{11}H_{12}(CH_3)$ , on the decomposition of its methyl iodide compound with potash.—A. C. W.

#### Concrete Flower Oils (So-called). Semi-Annual Report of Schimmel and Co., Oct. 1897, 86.

On account of its solubility in strong alcohol, myristic acid has lately been used for the preparation of "concrete flower oils." When submitted to distillation, or exposed to a temperature of 100° C., the following non-volatile residues were left with various samples of "concrete flower oils":—Jasmine, about 50 per cent.; Lilac, about 49 per cent.; Acacia about 69 per cent.; Rose, about 73.8 per cent.; Mignonette about 85 per cent.; Violet, about 86 per cent.—J. O. B.

#### Rosemary Oil. Semi-Annual Report of Schimmel and Co., Oct. 1897, 52.

In order to determine if the presence of pinene, previously noted in rosemary oil, was due to the addition of turpentine, or if that terpene was a natural constituent of the oil, a collection of rosemary leaves from several Dalmatian islands has been distilled in Leipzig and the oil examined. This oil was found to contain dextrogyrate pinene and camphene, and the same constituents were present in a good Italian sample of the oil. The mere presence of pinene cannot, therefore, alone, be regarded as evidence of adulteration.

Simple fractionation was found to be of little value in determining the quality of the oil, since the same oil gave different results according to the method of distillation, or the form of the retort employed. The variations of atmospheric pressure also greatly interfered with the result. Large additions of turpentine can, however, be detected in this manner, since when more than 20 per cent. of the oil distils below 170° C., it can safely be regarded as adulterated.

Small additions of French oil of turpentine can be detected by the rotation of the first fraction. This should always be dextrogyrate.

A pure rosemary oil should therefore possess the following characters:—Specific gravity should not fall below 0.900. The oil should be dextrogyrate. One volume of the oil should give a bright solution with  $\frac{1}{2}$  or more volumes of 90 per cent. alcohol; also with 10 parts of 80 per cent. alcohol.

The first fraction of 10 per cent. obtained by distillation should be dextrogyrate. The following figures were obtained from various specimens of oil distilled in Leipzig:—

—	Yield, per Cent.	Specific Gravity.	Rotation.	Rotation, First 10 per Cent. of Distillate.	Solubility in 80 per Cent. Alcohol.
1	1.40	0.913	+ 4 16	+ 1 30	1 in 1.2
2	1.70	0.909	+ 3 40	+ 1 22	1 „ 5.5
3	1.50	0.910	+ 5 56	+ 6 26	1 „ 5.0
4	1.73	0.904	+ 6 54	+ 7 49	1 „ 9.0
5	1.75	0.906	+ 8 52	+ 8 24	1 „ 0.7

The oils numbered 1 and 2 were found to contain 5.1 and 5.8 per cent. respectively, of bornyl acetate, with 16 and 18 per cent. of borneol.—J. O. B.

#### Cassia Oil, Note on Analysis of. J. O. Braithwaite. Pharm. Jour. 1897, 59, 1428, 397.

Attention is directed to the importance of carefully sampling this oil before submitting it to analysis for the aldehydic value, since it is well known that a wide variation in quality may occur in different bottles in the same consignment. Notwithstanding this, the practice appears to exist of giving analytical certificates on samples drawn from a limited number of bottles, which are erroneously taken to represent the aldehydic value of a large quantity of the oil. An original case of cassia oil, sold upon analysis as assaying from 80 to 85 per cent. of cinnamic aldehyde, was found to give 66, 78, 77, and 77 to 78 per cent. of that body respectively, from the four bottles it contained. The mean aldehydic value of this particular case of oil fell therefore just below 75 per cent.

Purchasers of this oil should stipulate, when buying on the basis of analytical results, that the oil actually purchased should have been examined, or else the whole consignment should be "worked" previous to analysis or should be efficiently sampled.—J. O. B.

#### Capsicum, Active Principle of. J. Morbitz. Pharm. Zeits. für Russ. 1897; through Pharm. Wochenschr. 1897, 14, [33], 525.

CAPSIUM fruits and powder were first freed from fat with petroleum spirit and then extracted with ether. The residue obtained on distilling off the ether was saponified with just sufficient solution of KHO, then again extracted with ether, and the solvent removed. The ethereal residues thus obtained were repeatedly extracted with hot petroleum spirit, from which, on cooling, small crystals separated, which the author regards as the active principle of the fruit, and which he terms capsacutin. The yield is only between 0.05 and 0.07 per cent. on the powdered drug. Capsacutin is neither glucoside, acid, nor alkaloid. It is extremely acid, the taste being still detected in a dilution of 1 in 11,000,000.—J. O. B.

#### Toxicodendrol: The Active Principle of *Rhus toxicodon* and *Rhus venenata*. F. Pfaff. Jour. Exper. Med., March 1897; through Med. Chron., Aug. 1897, New Ser. 7, 377.

THE author isolated the active principle, toxicodendrol, by extracting the plant with alcohol, distilling off the solvent, and treating the residue with ether, after washing it with water. On evaporating the ether, an oily residue was obtained, which was freed from resin by means of alcohol. By precipitating the alcoholic solution thus obtained, with an alcoholic solution of lead acetate, a compound of lead with the active oil was obtained. This, when decomposed with ammonium sulphide, liberated toxicodendrol as an oily substance possessing intensely irritating properties. It was found in all parts of the plant, the fruits giving 3.6, the leaves 3.3, and the stem 1.6 per cent. The degree of activity varied in the case of different persons; in some cases 1 mgrm. of the oil produced hundreds of vesicles, and even  $\frac{1}{1000}$  of a mgrm. proved active in one case. The vesicant action was not immediate, a period of 24 hours to 7 or 9 days elapsing before the eruption appeared.—J. O. B.

#### Dioscorine: Toxic Alkaloid from *Dioscorea hirsuta*. H. W. Schnette. Chem. Centr. 1897, 2, 130; through Pharm. Zeits. für Russl. 1897, 36, 379.

THE author has extracted this alkaloid, which was first isolated by Boorsma in 1839, by the following process:—

The dried tubercles were extracted by alcohol acidulated with HCl, fatty matter being precipitated by the addition of water, and the clear filtrate so obtained was evaporated to a syrup. This was made alkaline with KOH, and the liberated alkaloid shaken out with  $CHCl_3$ . On distilling off the solvent, the residue was neutralised with HCl, evaporated to dryness, dissolved in alcohol, and the hydro-

chloride purified by repeated crystallisation from that solvent. The base liberated from this salt was obtained as a greenish fluorescent syrup, which slowly crystallised in well-formed yellowish crystals, which melted at  $43.5^{\circ}\text{C}$ . These crystals were very hygroscopic, readily soluble in most solvents, except ether, benzene, and petroleum ether, and were insoluble in  $\text{CCl}_4$ . Dioscorine was found to be a powerful base, liberating ammonia from its salts; it reacted with litmus, and was slightly volatile. It was precipitated by most of the alkaloidal reagents. With  $\text{H}_2\text{SO}_4$  and  $\text{KIO}_3$  (pure) it gave a reddish-brown colour, quickly turning to purple; with sodium nitroprusside and an alkali it gave a reddish-violet colour. The hydrochloride  $\text{C}_{13}\text{H}_{19}\text{NO}_2\text{HCl} + 2\text{H}_2\text{O}$  crystallised in two forms—either in needles or tablets. It lost its water of crystallisation at  $37.7^{\circ}\text{C}$ ., and the anhydrous salt melted at  $95.5^{\circ}\text{C}$ . The specific rotation of the aqueous solution was  $[\alpha]_D^{20} = +4.40^{\circ}$ , and the refractive index of a 1.75 per cent. solution  $N_D^{20} = 1.3376$ . Dioscorine platinum hydrochloride,  $(\text{C}_{13}\text{H}_{19}\text{NO}_2)_2\text{H}_2\text{PtCl}_6$ , formed orange tablets, and melted at  $92-93^{\circ}\text{C}$ . The aurochloride  $\text{C}_{13}\text{H}_{19}\text{NO}_2\text{H}_2\text{AuCl}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$  occurred in yellow arborescent crystals, melting at  $77.2^{\circ}\text{C}$ .

The action of dioscorine on the animal organism was found to resemble that of picrotoxin. In toxicological examination it may be met with in the benzene solution from an alkaline medium, and by Stas-Otto's process is extracted by the alcohol.

Dioscorine, described by Boersma as accompanying dioscorine, is stated by the author to be identical with that alkaloid.—J. O. B.

*Cosaprine: A New Antipyretic.* Z. von Vámosy and B. Fenyvessy. *Therap. Monatsh.* 1897, **11**, [8], 428.

COSAPRINE is a sulphonic derivative of—

and occurs as a greyish-white amorphous powder, readily soluble in water, having a slight saline taste and an acid reaction. As an antipyretic, it is more active than antifebrine, and at the same time the toxicity is very materially reduced.—J. O. B.

*Phesine: A New Antipyretic.* Z. von Vámosy and B. Fenyvessy. *Therap. Monatsh.* 1897, **11**, [8], 428.

This newly introduced antipyretic is a sulpho-derivative of phenacetin. The constitution is given as—

It is a light reddish-brown, amorphous, odourless powder, with a slight acid and saline taste. It is very readily soluble in water, giving a Bismarck brown solution with a slight acid reaction.—J. O. B.

## PATENTS.

[*Ionone.*] *New Chemical Substance suitable for Perfumery, Confectionery, and the like; Manufacture of.* J. C. W. F. Tiemann, Berlin, Germany. Eng. Pat. 8736 (2nd Edition), May 1, 1893. (See also this Journal, 1891, 272, 417, 903, 972.)

By shaking together for several days a mixture of citral, acetone, and baryta water, extracting with ether, distilling off the solvent, fractionating the residue, collecting the part

boiling at  $138^{\circ}-155^{\circ}\text{C}$ . under 12 mm. pressure, and distilling off in a current of steam any unchanged citral and acetone, a substance is obtained which, after purification by distillation *in vacuo*, consists of "pseudo-ionone," a ketone boiling at  $143^{\circ}-145^{\circ}$  under 12 mm. pressure, and having the density 0.904. If pseudo-ionone be heated on an oil-bath with sulphuric acid, glycerin, and water, it is converted into ionone, which may be separated from the reaction mixture by extraction with ether and fractionation of the extracted portion, and further purified by conversion into its phenylhydrazine compound. Ionone,  $\text{C}_{13}\text{H}_{20}\text{O}$ , boils at  $128^{\circ}$  under 12 mm. pressure, and has the density 0.935. The patentee claims pseudo-ionone and ionone as new products of manufacture, and the processes for their preparation as described.—A. C. W.

*Violets, Artificial Essence or Essential Oil of; A New or Improved Process for the Manufacture of.* F. Fritzsche and Co., Hamburg-Ohlenhorst, Germany. Eng. Pat. 26,350, Nov. 21, 1896.

An essential oil, smelling of violets, boiling at  $142^{\circ}-150^{\circ}\text{C}$ . under 12 mm. pressure, and of density 0.948—0.952, is claimed as a new article of manufacture. This oil differs in physical properties from ionone (see preceding abstract). The patentee claims the process for the manufacture of artificial essence of violets, which consists in heating together lemon-grass oil, alcohol, acetone, and solutions of hypochlorites (bleaching powder not containing free lime), with or without the addition of cobalt nitrate, and the conversion of the oil so obtained, which boils at  $155^{\circ}-175^{\circ}$  under 12 mm., into an oil of violet-like odour by heating with sodium bisulphate.—A. C. W.

*Menthol, Impts. in the Preparation and Application of.* H. Helbing, London. Eng. Pat. 25,778, Nov. 16, 1896.

ACCORDING to this invention, the menthol is dissolved in ethyl chloride or methyl chloride, with the addition of alcohol, in the proportion of one part of menthol, one part of alcohol, and 18 parts of ethyl chloride. This solution is kept in glass or metal vessels, provided with a small orifice, which is closed with a tightly fitting cap. On removing the cap, the solution of menthol is ejected in the form of a fine spray.—W. P. S.

*Coating and Insulating Materials for Medical and Other Purposes, Impts. in the Preparation and Application of.* H. Helbing, London, and G. Pertsch, Lyons, France. Eng. Pat. 25,779, Nov. 16, 1896.

THIS invention relates to the preparation and application of coating solutions (adhesive plasters and collodions). For this purpose, solutions of various gums, fatty matters, wax, gutta-percha, or nitro-cellulose are dissolved in a large excess of methyl or ethyl chloride (with or without the addition of alcohol or ether). These solutions are placed in glass or metal receivers, having small orifices, which are closed with tightly fitting caps. If necessary, iodoform or other soluble antiseptics may be incorporated in the solutions.—W. P. S.

*Acetonalkamines, The Manufacture of Isomeric Unsymmetrical, and Acidyl Derivatives therefrom.* Chemische Fabrik auf Actien vormalis E. Schering, Berlin, Germany. Eng. Pat. 26,666, Nov. 24, 1896. (See this Journal, 1897, 758, 822.)

THE production of isomeric unsymmetrical bases of the acetonalkamine series by separating by crystallisation the mixture of unstable and stable alkamines formed by reduction of the unsymmetrical acetonamine bases, the conversion of these alkamines into the stable form by the action of alkylates, and the production of acidyl derivatives from the stable and unstable forms by replacing the hydroxyl hydrogen by acid radicals (benzoyl, toluyl, mandelic acid, &c.), are claimed, together with the compounds mentioned, as new chemical products.—A. C. W.

*Guaiacol and Creosote, Impts. in the Manufacture of Preparations of.* G. B. Ellis, London. From La Société Chimique des Usines du Rhône, formerly G. P. Monnet

et Cartier, Lyons, France. Eng. Pat. 27,527, Dec. 3, 1896.

The substances claimed are the phosphites of guaiacol and creosote, prepared by either of the following methods:—

(1.) Three molecular equivalents of guaiacol or creosote are dissolved in an alcoholic solution of caustic soda or potash, containing a sufficient amount of alkali to form the salts of guaiacol or creosote. To this mixture is slowly added one molecular equivalent of phosphorus trichloride, keeping the solution cool during addition. The mixture is then heated to boiling, and when all the alcohol has evaporated, any uncombined guaiacol or creosote may be removed by washing with aqueous alkali. The residual phosphorous acid ester is then purified by recrystallisation.

(2.) 372 parts of guaiacol are mixed with 137 parts of phosphorus trichloride and heated to 200° C., until no more hydrochloric acid fumes are given off. After cooling, the residue is treated with caustic soda, extracted with ether, and, finally recrystallised from alcohol. The yield by this method is not as large as by the former one.

The guaiacol phosphite obtained forms a white crystalline powder, with a faint odour of creosote. It is readily soluble in alcohol, ether, chloroform, and fatty oils; soluble with difficulty in water, glycerin, benzene, and acetone. Melts at 77.5° C.

Creosote phosphite is a yellow syrupy liquid with a faint odour of creosote.—W. P. S.

[Saccharine.] *Benzoic Sulphinide, Impts. in the Manufacture of.* La Société Chimique des Usines du Rhône, Lyons, France. Eng. Pat. 27,655, Dec. 1, 1896.

THE process for the manufacture of saccharine and its stages are claimed, which consist in heating *o*-benzaldehyde sulphonic acid with phosphorus pentachloride and oxychloride, distilling off the oxychloride, heating the chlorinated compound with ammonia under high pressure after recrystallisation, acidifying the contents of the autoclave and extracting with ether.—A. C. W.

*Toluene, Chlorine Derivatives of; Impts. in the Manufacture of.* La Société Chimique des Usines du Rhône, Lyons, France. Eng. Pat. 29,717, Dec. 24, 1896.

WHEN *o*- or *p*-toluenesulphonic chloride is distilled alone at the ordinary pressure, sulphur dioxide and *o*- or *p*-chlorotoluene are obtained. The decomposition takes place more easily and at a lower temperature if chlorine be passed through the sulphonic chloride. The patentee claims the process for preparing chlorotoluenes, which consists in passing chlorine through heated *o*- or *p*-toluenesulphonic chlorides; the manufacture of *o*-chlorobenzaldehyde,  $C_6H_4Cl \cdot CHCl_2$ , by passing the current of chlorine at 150–200° until 2 mols. of chlorine are absorbed, distilling the product, and collecting the fraction 225°–235° C.; the manufacture of *p*-chlorobenzaldehyde or *p*-chlorobenzoehloride by the similar action of chlorine on the *p*-sulphonic chloride, followed by fractionation.—A. C. W.

*Orthotoluene Sulphonic Acid and Thio-orthobenzoic Acid [for Saccharine], a Process for the Preparation of, by Oxidation of Thio-ortho cresol.* J. Hauff, Stuttgart, Germany. Eng. Pat. 10,810, April 30, 1897.

THE above acids forming the raw materials used for the preparation of the pure benzoyl orthosulphonic imide have not hitherto been obtained on a large scale in a direct manner and pure form. It has been found that on treating thio-ortho cresol, prepared according to the methods described by Leuckart (J. Prakt. Chem. 1890 [2], 41, 186) and Lustig (Gazzetta, 21, 213), with suitable oxidising agents, preferably potassium permanganate, orthotoluene sulphonic acid is formed in the first place, whilst on further oxidation, the methyl group is transformed into the carboxyl group with formation of thio-orthobenzoic acid.

For the preparation of orthotoluenesulphonic acid, 12 kilos. of thio-ortho cresol are mixed with 13 kilos. of caustic soda (40 per cent. NaHO), 32 kilos. of potassium permanganate, and about 100 litres of water. The solution is heated until the red colour has disappeared; it is then

filtered, neutralised, and evaporated to dryness. For the manufacture of thio-orthobenzoic acid, the following proportions are used: 12 kilos. of the thio cresol, 13 kilos. of caustic soda (40 per cent.), 64 kilos. of potassium permanganate, and 2000 litres of water. The treatment of the solution is the same as in the previous case.

It is obvious that this synthesis can be applied to the halogen-sulpho- and nitro-substitution products of the thio-ortho cresol substituted in the benzene nucleus, whereby the corresponding substitution products of ortho-toluenesulphonic and thio-orthobenzoic acids are obtained.—H. B.

*Iron for Medicinal Purposes, and Solvent Thereof; the Manufacture of Improved Preparations of.* A. D. Brenen, Bremen, Germany. Eng. Pat. 15,178, June 24, 1897.

THE iron specific forming the subject of this invention contains iron pyrophosphate in a suspended state, which is obtained by the addition of a solution of sodium pyrophosphate to a solution of diluted ferric chloride, the sodium chloride being removed as it forms. As this preparation of iron is insoluble and is only dissolved in the stomach at the expense of the gastric juice, a solvent is provided consisting of a mixture of sodium pyrophosphate, sodium bicarbonate, and tartaric or citric acid, with sugar or saccharine, and a flavouring material, as citron oil. The iron preparation may be flavoured with suitable extracts. The solvent is, of course, taken into the stomach after taking the iron milk. Molasses and alcohol, when added, serve to hold the iron precipitate in suspension, and to enhance the "keeping" properties of the preparation.

—W. P. S.

*Hexamethylouetetramine and its Chloral, Bromal, and Butylchloral Derivatives, Impts. in the Process for the Preparation of.* L. Lederer, Munich, Germany. Eng. Pat. 17,693, July 28, 1897.

FORMALDEHYDE and ammonia unite to produce hexamethylenetetramine. The patentee finds, in contradiction to Wohl (Ber. 19, 1842) that the solution obtained is not decomposed by evaporation under diminished pressure. He therefore claims the process which consists in heating under diminished pressure aqueous solutions of formaldehyde and ammonia or ammonium carbonate, the purification of the product by extraction with alcohol, the process for preparing the chloral, bromal, or butylchloral derivatives, which consists in bringing formaldehyde, ammonia, or ammonium carbonate, and the chlorinated aldehyde into reaction, and the processes for separating these derivatives from their solutions, which consist in evaporation in a partial vacuum or in saturation by a neutral salt.—A. C. W.

## XXII.—EXPLOSIVES, MATCHES, Etc.

### PATENTS.

*Signals, Charges of Detonating Railway Eng; Impts. in the.* T. Jenkins, Birmingham. Eng. Pat. 26,819, Nov. 28, 1896.

THE object of this invention is to dispense with the use of percussion caps and anvils or like ignition devices, and also to wholly or partly replace the ordinary powder charges by explosive charges capable of being exploded when struck or crushed.

The explosive mixtures suggested are potassium chlorate, sulphur and fine sand, or chlorate, red phosphorus, sodium bicarbonate and glue, or other chlorate mixtures.

The details of arranging the signals are given in the specification, which is accompanied with drawings.—W. M.

*Explosives, Impts. in.* G. Kynoch and Co., Ltd., and A. T. Cocking, Wotton, Warwickshire. Eng. Pat. 28,889, Dec. 16, 1896.

THE object is to produce a "safety" explosive, and the claim is for the "combination with nitroglycerin of barium nitrate or other similar nitrate, wood meal, and ammonium oxalate, or other similar oxalate, with or without the admixture of sodium carbonate."—W. M.

*Sulphuric Acid "Spent Acid in Nitroglycerin Making," Impts. in Purifying and Concentrating, in part applicable to the Manufacture of Nitric Acid.* G. Kynoch and Co., Ltd., and A. T. Cocking, Witton, Warwick. Eng. Pat. 28,891, Dec. 16, 1896.

Thin weak sulphuric acid resulting from the manufacture of nitroglycerin is placed in a strong cast-iron still, set over a fire, and connected to a cooling coil, communicating with a series of Woulff's bottles, the last of which is connected with an exhaust pump. By the aid of heat and the partial vacuum obtained, nitrous fumes are disengaged from the acid and collected in the bottles. The process is continued until the acid is concentrated, when sodium or potassium nitrate may be added, if it be desired to obtain nitric acid, and the process is recommenced, thus avoiding the removal of the sulphuric acid from one vessel to another.

—E. S.

*Powder Gases at various Points in the Lengths of Gun-barrels, Improved Apparatus for Measuring the Pressures of.* J. Polain, Liège, Belgium. Eng. Pat. 12,792, Jan. 2, 1897.

See third abstract below.

## XXIII.—ANALYTICAL CHEMISTRY.

### APPARATUS, ETC.

*Filter Papers, The Reaction of.* L. Magnier de la Source. Rev. Intern. falsific. 10, 165; Chem. Centr. 1897, [2], 909.

THE author confirms the observation of Gans (Zeits. für angew. Chem. 1889, 669), that if, in the course of analysis, a boiling solution of potassium bitartrate be filtered through ordinary filter paper, the results of the estimation of the former will be too high. In order to account for this fact, the reactions of several kinds of filter paper were tested, and it was found that some were of an acid and some of a basic character. In the case of the latter, a certain quantity of acid is retained by the filter paper and cannot be removed by washing. A compound of the acid with cellulose is formed and has been separated by the author. In the estimation of acid tartrate of potassium, it is recommended to use a filter paper which has been well washed with boiling water.—A. S.

### PATENTS.

*Firedamp in the Atmosphere of Mines and other Places ["Gas Battery"]; Improved Method of and Apparatus for Detecting and Indicating the Presence of.* E. L. Mayer, London. Eng. Pat. 23,822, Oct. 26, 1896.

"1. THE . . . method of detecting and indicating the presence of firedamp in the atmosphere of mines and other places by causing such firedamp to generate an electric current, by means of a gas battery or gas cell [platinum electrodes preferably coated with black or spongy platinum, dipping in electrolyte of dilute sulphuric acid, '4 parts of water to 1 of acid'], and utilising such electric current by means of a galvanometer or equivalent apparatus, capable of being actuated by a weak electric current, to produce a signal, or to control, either directly or indirectly, another electric circuit by which a signal will be produced. . . . Other six claims relate to apparatus and methods of employment. Eng. Pat. 18,188 of 1895 is referred to (this Journal, 1897, 162).—J. C. R.

*Powder Gases at Various Points in the Lengths of Gun-barrels, Improved Apparatus for Measuring the Pressures of.* J. Polain, Liège, Belgium. Eng. Pat. 12,792, Jan. 6, 1897.

THIS specification is accompanied by drawings. The apparatus "consists of a gun barrel having a series of holes bored through the side thereof at right angles to the axis, a sleeve or casing, wholly or partially enclosing the said gun barrel, and having a series of holes formed therethrough, the axes of which are in line with the axes of the holes in the gun barrel, and a device applied to each of the said

holes in the sleeve or casing and gun barrel adapted to hold a copper cylinder in place, on the head of a piston or plunger subjected to the pressure of the powder gases."

The "device" consists of a perforated plug, a set-screw, and a piston or plunger.—W. M.

*Test Papers and Receptacles for same, Impts. in.* S. S. Bromhead, 97, Newgate Street, London. From The Chemische Fabrik and E. Dieterich, Helfenberg, Germany. Eng. Pat. 18,096, Aug. 3, 1897.

THE test papers are made in ribbon or tape form, either plain or perforated transversely at intervals, and are enclosed in a cylindrical case or box formed with a slot through which the paper can be withdrawn as required.—R. A.

## INORGANIC CHEMISTRY.— QUANTITATIVE.

*Potassium, Estimation of, by Reduction of the Potassium Platinic Chloride with Sodium Formate.* B. Sjollem. Chem. Zeit. 1897, 21, [74], 739–740.

AFTER describing the inaccuracies and difficulties met with in applying the usual methods for determining potassium, the author gives a method based on that of Corenwinder and Contamine (Bull. de la Soc. Ind. du Nord, 1879). A portion of the solution to be examined, containing 0.5 gm. of substance, is faintly acidified with hydrochloric acid, mixed with platinic chloride solution without previous precipitation of sulphuric acid, and evaporated to a syrup over the water-bath. When the mass is completely cooled, a mixture of 9 parts of a 95 per cent. alcohol and 1 part of ether is poured over it; it is then allowed to stand for some hours, is washed with the same mixture, and transferred to a filter. The double potassium platinic chloride is then dissolved by pouring boiling water over it, and the hot solution is reduced in a porcelain basin with the aid of sodium formate, or, better, the hot chloride solution is gradually poured into the boiling solution of the formate. A glass beaker is to be preferred, however, to a porcelain dish, because, if covered with a watch glass, there is no fear of spitting, and because there are no cracks in the glaze which can retain reduced platinum. With sufficient formate the solution speedily becomes decolorised; it is heated for some time to cause the agglomeration of the platinum and to enable the precipitate to be washed readily. The reduced metal is thrown on to a filter, the beaker being rinsed with dilute acid; the precipitate is finally washed with boiling water, dried, ignited, and weighed. The method is free from most of the usual faults, and is more rapid than those commonly employed, whilst it affords good results. The author prefers to use 90 per cent. alcohol in place of the alcohol and ether recommended by Corenwinder and Contamine.—W. G. M.

*Sulphur Chloride, Analysis of.* G. A. Le Roy. Rev. de Chim. Indust. 1897, 8, [94], 294–295.

SULPHUR chloride ( $\text{S}_2\text{Cl}_2$ ) contains normally 47 per cent. of sulphur, and 52 per cent. of chlorine, but commercial samples often differ widely from this proportion, containing an excess of one or the other element in solution without the physical properties of the substance being sensibly altered. It is, however, essential, in the industries which make use of sulphur chloride (Vulcanisation of rubber; Manufacture of artificial india-rubber; Treatment of ores containing gold, &c.), that its composition should be as normal and constant as possible. The only method of analysing it to be found in the text books is that of Rose, in which the sulphur is estimated by oxidation with fuming nitric acid and precipitation as barium sulphate and the chlorine determined by difference, but the author agrees with Rose in considering this tedious, and liable to error. In place of it he recommends a modification of his volumetric process (Bull. Soc. Indust. Rouen, 1890, 374). From 1 to 2 grms. of the sulphur chloride are pipetted into a weighed quantity of pure benzene, which is again weighed after the addition to obtain the amount of sulphur chloride taken. The mixture is then made up to a definite volume with benzene, and an aliquot portion taken

for the determination. This is shaken with a known volume of soda solution containing 19.37 grms. of  $\text{Na}_2\text{O}$  per litre (1 c.c. = 0.01 grm. sulphur), and the sulphur chloride is gradually decomposed into sulphide, sulphite, hyposulphite, sulphate, and chloride of sodium, with the separation of some free sulphur. This is dissolved by warming the flask on a sand-bath, on which the benzene is subsequently evaporated off. When the sulphur has completely disappeared, an excess of hydrogen peroxide (neutral and free from substances precipitated by silver nitrate) is added, and the liquid warmed, in order to convert the various sulphur compounds of sodium into sulphate. After removing the excess of hydrogen peroxide by boiling, with the addition, if necessary, of a few drops of permanganate, the liquid is cooled, and titrated with normal nitric or sulphuric acid. The amount of soda found free plus that belonging to the sodium chloride subsequently determined, deducted from the original quantity taken, gives the amount of soda converted into sulphate, and this multiplied by 0.01 gives the amount of sulphur. The chlorine is then determined in the neutralised solution by titration with silver nitrate.—C. A. M.

*Sodium Sulphide used in Leather-Dressing. Note on the Analysis of the.* F. Jean. Ann. de Chim. Analyt. 2, [18], 341–342. Analyst 1897, [260], 306.

Two samples of sodium sulphide were examined, one which had produced spots (recognised as due to iron) on doe-skin during the cleansing and plumping processes—giving a green aqueous solution, depositing a sediment of iron sulphide, and the other giving a yellow solution and no deposit of iron sulphide. The method of analysis was as follows:—10 grms. were dissolved in water, and the iron sulphide filtered off. The filtrate was made up to a litre, and the total sulphur determined in 10 c.c. by titrating with  $\frac{1}{100}\text{N}$  iodine solution and starch paste. A second 10 c.c. are mixed with 30 c.c. of water and a quantity of ammonium sulphate solution (6.7 grms. of  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  per litre) equal to the volume of iodine used in the first test and the mixture distilled, the distillate being collected in a receiver containing 2 c.c. of  $\frac{1}{100}\text{N}$  acid. The operation is suspended when the distillate coming over ceases to have an alkaline reaction. The excess of acid in the receiver, after boiling to expel hydrogen sulphide, is titrated with  $\frac{1}{100}\text{N}$  alkali, and each c.c. of acid neutralised by the distilled ammonia, corresponds to 0.0039 grm. of sodium sulphide. The residual liquor in the retort is cooled and titrated with  $\frac{1}{100}\text{N}$  iodine solution (1 c.c. = 0.0079 grm. of sodium thiosulphate). The difference between this and the former iodine titration is calculated as sodium sulphide. If this amount be larger than the amount of sulphide found by the acid titration, the difference represents, in terms of  $\text{Na}_2\text{S}$ , the excess of sulphur present as polysulphide, and may be calculated to sulphur (100  $\text{Na}_2\text{S}$  = 41.8). The composition of the two samples examined was:—

Green Sulphide. Yellow Sulphide.

Water .....	63.24	60.32
Sodium sulphide .....	31.20	28.08
Sulphur in excess .....	0.53	1.20
Sodium thiosulphate .....	4.70	10.60
Iron sulphide .....	0.33	0.40

It was noted in the course of the investigation that (1) when a solution of an alkaline monosulphide is boiled with excess of ammonia, part of the sulphur is volatilised as ammonium sulphide; (2) when sodium thiosulphate is boiled with excess of ammonium sulphate, ammonium sulphide is liberated and sulphur deposited: this decomposition does not take place in presence of alkalis.—A. S.

*Sulphuric Acid, Volumetric Determination of Combined.* F. Marboutin and M. Molinik. Bull. Soc. Chim. (3), 17, [22], 950–952 and 953–955.

The authors have determined the corrections to be applied to Windisch's method when, instead of using exactly equivalent solutions of barium chloride and potassium chromate, a slightly stronger solution of the latter is

employed. The results obtained by means of this modification agree closely with those obtained by Windisch's method, which has been abandoned, however, on account of the difficulty of accurately titrating arsenious acid with iodine in presence of chromium salts, in favour of the method described in the abstract which follows below:—

To 100 c.c. of the water to be tested, after acidulating with hydrochloric acid and boiling to expel carbonic acid, 30 c.c. of barium chloride solution are added drop by drop. After allowing the precipitate to settle at 40° the acid is neutralised with a few drops of ammonia, the liquid gently warmed, and 30 c.c. of potassium chromate solution added. The volume is made up to 300 c.c., and to 100 c.c. of the clear supernatant liquid, 2 c.c. of sulphuric acid (1 part acid to 3 parts water), and 5 c.c. of arsenious acid solution are added, and the mixture gently warmed and stirred until decolorised. The excess of acid is then neutralised with potassium carbonate and the arsenious acid titrated with iodine. If  $n$  represent the volume of iodine solution used for 100 c.c. of diluted water,  $n'$  the volume for 100 c.c. of the water to be tested,  $t$  the amount of iodine in 1 c.c. of iodine solution, then the quantity of  $\text{SO}_4$  per litre,  $x$ , =  $10(n - n') \frac{3}{4} \cdot \frac{6 \times 127}{1 \times 80}$ . A blank experiment is made with distilled water.

The solutions employed contain respectively 4.8 grms. of crystalline barium chloride, 3.9 of crystalline potassium chromate, 4.95 of arsenious acid dissolved in potash and then made slightly acid with sulphuric acid, and 2.54 of iodine per litre. The last is the only one which requires accurate standardisation. The method involves neither filtration nor washing, and impurities in the reagents are said not to affect its accuracy.—E. W. W.

*Crucibles, Ground Graphite; Notes on the Assay of.* A. F. Crosse. Chem. and Metall. Soc. of South Africa. Proc. at Meeting of Sept. 18, 1897, 11–12.

The common method of roasting the graphite with nitre is unsatisfactory, because of the amount of nitrate required and because a trial assay is necessary. The author prefers to use manganese peroxide, which leaves a residue that is neither reducing nor oxidising in its action. 10 grms. of the finely-crushed crucible are mixed with 35 grms. of the powdered binocide, and heated to a bright-red heat in a Hessian crucible. The manganese becomes converted into  $\text{Mn}_2\text{O}_3$ , and a solid cake is formed at the bottom of the crucible. The temperature is reduced, and a mixture of 160 grms. of flux (2 of potassium carbonate with 1 of borax and 1 of salt), 50 of litharge, and 2 of flour, and 20 of silica are added. The mass fuses quietly, and when ready, the crucible is cooled and broken up. The lead contains all the gold, and the slag is clean and brown in colour. The average of four such assays should be reported, a single sample being insufficiently representative. Simple roasting of the powdered graphite sometimes suffices for its removal, but the operation is very slow and the results are often lower than those obtained with the aid of manganese peroxide, probably on account of volatilisation in the muffle. Experiments in extraction with aqua regia (even in excess) failed to extract more than two-thirds of the gold. Treatment with bromine water containing liquid bromine led to a solution of the gold in the upper part of the glass vessel used, but reprecipitation occurred lower down, and a colourless solution free from gold was obtained on filtration.—W. G. M.

*Iron Ores, Method for Estimating the Reducibility of.* J. Wilborth. Chem. Zeit. 1897, 21, [75], 750–752.

The reduction apparatus used, consisted of a gas-producer of circular section, 0.25 m. in diameter and 1.2 m. high, in which was suspended centrally an iron tube of 50 mm. diameter; through this the producer gases were passed over the samples to be tested for any required length of time. Wood charcoal was thus burnt with the aid of natural draught, and provision was made for the combustion of the excess gas. The ore to be examined was crushed to pass a sieve of 19 meshes per sq. cm., and was suspended in the reduction tube in baskets of iron wire gauze by means of iron wire. At first 30–40 grms.

of ore were used for each experiment, but subsequently three baskets of kidney shape in section were used, each containing 8–10 grms. of ore, and placed with the others within a larger basket, but separated from one another by thin plates, to prevent any chemical interaction. In this way two different ores might be compared with a standard sample. The temperature was determined by means of metallic alloys and by a thermophone. (This Journal, 1896, 741.) At a distance of 500 mm. from the upper end, the temperature was  $400^{\circ}\text{C}$ ., at 900 mm. it was  $525^{\circ}$ , at 1,200 mm. it was  $700^{\circ}$ , and at 1,500 mm.  $800^{\circ}$ – $880^{\circ}\text{C}$ . A bent glass tube was introduced through an opening to remove samples of gas for analysis, which showed that the  $\text{CO}_2$  in the gases ranged from 3.2 to 3.6 per cent., and the  $\text{CO}$  from 30 to 32 per cent. The ore could be gradually or suddenly introduced into the hottest part of the tube, but the former method was preferred, since at  $400^{\circ}\text{C}$ . a separation of carbon was likely to occur, but the same effect could be obtained by retaining the ore at  $400^{\circ}$  for an hour, and then plunging it direct into the hottest part for another hour. At the end of the experiment, the baskets were cooled in a current of carbonic oxide, to prevent re-oxidation of metallic iron; the ore was then removed and at once tested. But at these high temperatures the ore is so reduced as to contain ultimately, metallic iron and carbon as well as oxide, and therefore requires very careful analysis. The amount of oxygen present after reduction may be taken to indicate the grade of oxidation of the iron. The various tests are thus made:—

(a) *Determination of Carbon*.—Särnström's apparatus is used, the carbon being burnt by chromic-sulphuric acid to  $\text{CO}_2$ .

(b) *Estimation of Metallic Iron*.—The reduced ore is treated with dilute sulphuric acid, and the evolved hydrogen is collected to serve as a measure of the iron left. From 0.2 to 1.0 gm., according to the degree of reduction, is placed in a test tube and covered with a few c.c. of water; the tube is then closed with a caoutchouc stopper, through which is passed a bent tube and a funnel having a stop cock. The bent tube is connected with the neck of a 200 c.c. bottle, communicating in turn by an india-rubber tube (leading from a tubulure at the bottom) with the bottom of a burette. This bottle contains about 160 c.c. of an alkaline solution to absorb any  $\text{CO}_2$  that might be present in the gas, and is immersed throughout in water of constant temperature. When the ore has been placed in the test tube, the apparatus is closed, and the tube is immersed in water at  $20^{\circ}\text{C}$ .; the liquid in the burette is then brought to the same level as that in the bottle, and the reading is taken. The burette is next alternately raised, lowered, and levelled to test the soundness of all the joints. In c.c. of dilute (1:8) sulphuric acid is then run from the stop-cock funnel into the test tube, and is allowed to act for an hour at the ordinary temperature, after which the mixture is carefully raised to the boiling-point, the burette being lowered to prevent the pressure becoming excessive. When no more gas is evolved, the tube is cooled first in air and then in a beaker of water at  $20^{\circ}\text{C}$ ., and the reading of the burette is taken as before. In this way the difference in volume of gas in the apparatus represents the hydrogen evolved, of which 39.8 c.c. at  $0^{\circ}$ , or 42.7 c.c. at  $20^{\circ}\text{C}$ ., correspond to 0.1 gm. of metallic iron. When much combined carbon is present in iron, the amount of hydrogen corresponding to the iron taken is much reduced, owing to the formation of hydrocarbons, but in these experiments the amount of iron carbide formed is negligible. A small volume of hydrogen, however, might possibly be produced by the reduction of some of the oxide by its agency.

(c) *Determination of Total Iron* was effected by solution in  $\text{HCl}$ , evaporation with  $\text{H}_2\text{SO}_4$ , reduction with zinc, and titration with permanganate.

(d) *Determination of Oxidation Grade*.—0.4 gm. is weighed into a test tube provided with a glass stopper having only a minute opening. Here it is treated with 5 c.c. of dilute (1:10)  $\text{H}_2\text{SO}_4$ , with frequent shaking for  $\frac{1}{2}$ –1 hour until dissolved. When gas evolution has ceased,  $\frac{1}{2}$  c.c. of strong (sp. gr. 1.23) acid is added, and the whole is warmed until the iron is completely dissolved,

when it is titrated in a beaker with permanganate. With ores difficult of solution, the clear liquid is poured off from any insoluble residue, which is then treated again with strong acid, the two filtrates being mixed before titrating. Thus the total iron in the test is found, but the metallic iron and ferrous oxide are already known, so that the oxidation grade is readily found. Thus, if the total iron be  $n$ , the metallic iron  $r$ , the ferrous oxide  $m$ , the oxidation grade is calculated from the following equation:—

$$\frac{3(n-r)}{2} : (m-r) + 3 \left[ \frac{(n-r) - (m-r)}{2} \right] = 100 : x$$

$$x = \text{oxidation grade} = 100 \times \left[ 1 - \frac{(m-r)}{3(n-r)} \right]$$

In this way the oxidation grade of  $\text{Fe}_2\text{O}_3$  is 100, of  $\text{Fe}_3\text{O}_4$  is 88.9, and of  $\text{FeO}$  is 66.7.

(e) *Determination of Reduction Grade*.—As a measure of reducibility (or reduction grade) the quantity of iron reduced is taken, expressed as a percentage of the total iron present in the ore.

From the experiments made it may be concluded that: In proportion as the oxidation grade 77.8 is attained at low temperatures, the ore is easily reducible, i.e., may be reduced by producer gas to metallic iron. This oxidation grade forms a point of equilibrium during the reduction, and metallic iron is not produced until this point is attained. But when reduction has proceeded so far, it progresses rapidly, and metallic iron is formed, while the number representing the oxidation grade gradually falls, without the ferrous oxide forming a second and more marked point of equilibrium as some metallurgists have assumed.—W. G. M.

*Ferro-Silicon, Commercial*. E. Donath and M. Haissig. *Stabl. u. Eisen*, 1897, 17, 670; *Chem. Zeit. Rep.* 1897, 26, 205.

FIG-IRON, when it contains more than 5 per cent. of silicon, is termed ferro-silicon; commercial samples of this material rarely contain more than 15–16 per cent. of silicon. The analysis of the substance is troublesome, especially in regard to the estimation of the total carbon. Silicon causes the separation of carbon as graphite, but both amorphous and combined carbon are present in the ferro-silicon. Hydrochloric and nitric acids and aqua regia are almost without action upon this material, which, for analytical purposes, must be fused with sodium carbonate and nitre, after which all the constituents, excepting carbon, may be determined. Dilute hydrofluoric acid is a good solvent and leaves the graphitic carbon in such form that it contains 0.36 per cent. of hydrogen and 4.7 per cent. of ash, but gaseous hydrocarbons escape at the same time. A sample containing 14.32 per cent. of Si thus showed 1.43 per cent. of C. Combustion with a boiling mixture of sulphuric and chromic acids, with or without previous treatment in sodium-copper chloride solution, gave numbers agreeing with those obtained by the hydrofluoric method for graphitic carbon. Direct combustion (after finely crushing) with lead chromate, as in elementary analysis, showed 2.79 per cent. of C; and the same result was obtained by the combustion of the residue from chlorine treatment in chromic and sulphuric acids. That the excess of 1.36 per cent. of C thus obtained cannot be present in the form of temper, carbide, or hardening-carbon is shown by its behaviour towards various oxidising agents, whilst its solubility in hydrofluoric acid points to its not being present as a carbide of silicon. The authors believe it exists as an unknown iron-silicon carbide.—W. G. M.

*Separation of Metals, Studies on the Electrolytic*. A. Waller. *Zeits. f. Elektrochem.* 1897, 4, [10], 241–247.

I.—*Separation of Cadmium and Zinc*.—Neumann by determining the potentials exhibited by these two metals in equivalent normal solutions of their salts has shown that a difference of about 0.345 volt exists. Le Blanc's experimentally determined decomposing values are 2.35 and 2.03 volts for the zinc and cadmium sulphate salts respectively. These confirm Neumann's figures and prove that a separation of the metals is possible by maintenance of the E.M.F.

between these two limits. The following methods are based upon this principle:—

(a.) *Deposition from Acid Solutions.*—Heidenreich has recommended the addition of sulphuric and acetic acids, while Smith and Luckow have recommended solutions prepared with acetic acid and sodium acetate. This method yields very correct results, as a comparatively high E.M.F. is requisite to bring any of the zinc down with the cadmium deposit in acid solutions, but it suffers from the disadvantage that the remaining solution must be neutralised before deposition of the zinc is possible.

(b.) *Deposition from Solutions of the Double Cyanides.*—This method, proposed by Beilstein and Jawein, has yielded good results in the hands of Freudenberg, but it demands much time and the deposit has a tendency to assume a spongy character.

(c.) *Deposition from Solutions of the Double Oxalates.*—This method, first proposed by Classen, has been independently examined by Eliasberg and by the author. Varying proportions of the two metals in the form of oxides were used in these tests (0.08 to 1.2 grms.), and, after conversion into chlorides, 8 grms. of potassium oxalate and 2 grms. of ammonium oxalate were added, and the solution was made up to 120 c.c. for electrolysis. The best deposits of cadmium were obtained at a temperature of 80–85° C. The E.M.F. at the terminals of the cell must not exceed by more than 0.30 volt the E.M.F. requisite to produce decomposition of the cadmium salt. As the mean resistance of the cell in the author's experiments was = 10 ohms, it follows that a current intensity of 0.03 ampère was the maximum possible, and one of 0.02 ampère was usually employed. The author's results confirmed those of Eliasberg, both the deposits of cadmium and zinc being perfectly satisfactory in character and completeness. The latter metal is deposited from a tartaric acid solution as recommended by Classen after removal of the cadmium. The oxalate method for separating cadmium and zinc is therefore recommended.

II. *Separation of Zinc and Cobalt.*—Neumann has determined the potentials of these two metals when immersed in their salt solutions, and has shown that the difference varies between 0.518 and 0.551 volt. Le Blanc has shown that the decomposing values for the sulphates are 2.35 and 1.92 volts. The differences are sufficiently great to permit the separation to be effected by a method similar in principle to that described for cadmium and zinc. The following methods have been proposed:—

(a.) *Deposition from an Ammoniacal Solution.*—This method is recommended by Fresenius and Bergmann. The deposition of the cobalt is satisfactory, but that of the zinc is only possible after the solution has been neutralised and has been made feebly acid.

(b.) *Deposition from a Double Oxalate Solution.*—This method is satisfactory for the determination of cobalt alone, but as it is necessary to raise the current intensity in order to separate the last traces of the cobalt, there is great danger of obtaining a deposition of zinc with the cobalt, and the method cannot be recommended.

(c.) *Deposition from Solutions containing Tartrates.*—This method has been recommended by Vortmann, but it suffers from the disadvantage that cobalt sesquioxide separates at the anode. The addition of potassium iodide and sodium hydrate, as recommended by Vortmann, does not entirely avoid this evil, but experiments made by Dr. Burekhardt, have shown that the addition of hydroxylamine and sodium hydrate effect what is desired. The author has repeated Vortmann's experiments, and has shown, that if the deposit of oxide upon the anode be weighed, and the weight be included with that of the metal found upon the cathode, the results are satisfactory. The method is therefore recommended.

III. *Separation of Antimony and Tin.*—Neumann has determined the potential of these metals when immersed in acid solutions of their chlorides, and has found a difference of 0.291 volt; but no accurate forecast of the difference in the case of alkaline solutions is possible from these figures. Classen has shown that antimony alone is deposited from the sodium sulpho salt solutions of these metals, and that the tin can be deposited from the remaining solution on

conversion into the ammonium sulpho salt. Classen has stated that either strong or weak currents may be used to effect the deposition of the antimony, whereas Ost has stated that tin is deposited with the antimony when the current intensity exceeds 0.30 amp. re. The author has calculated the decomposing value of the antimony sulpho salt of sodium from some of Ost's experimental data, and shows that this is about 0.26 volt in the solution at 15° C. and about 0.76 volt at 70° C.

The author has repeated Ost's experiments. In order to obtain good deposits of antimony from the sulpho salt solution, it is necessary to use pure sodium sulphide, prepared according to Classen's method. The weighed portions of the antimony and tin salts were dissolved in 80 c.c. of this solution, from 2 to 3 grms. of pure sodium hydrate in solution were added, and the solution of the mixed salts was diluted to 120 c.c. The electrolysis was carried out at 60° C. with E.M.F.'s varying from 0.65 to 1.60 volts, and with currents ranging from 0.30 to 1.5 ampères in intensity. The results of 16 determinations proved that the decomposition value of the tin sulpho salt of sodium was about 0.75 volt, or 0.40 volt lower than it was assumed to be from Ost's experiments. The author points out that varying amounts of free alkali may be the cause of this difference. In the author's series of experiments it was found that tin was deposited with the antimony at the cathode when the E.M.F. at the terminals exceeded 0.75 volt, and the error caused by this admixture increased with the voltage employed. It is, therefore, necessary, when using this method to effect the separation of antimony and tin, to pay attention, not to the current strength, but to the E.M.F. at the cell terminals. This, when using a solution at a temperature of 65° C., must never be allowed to exceed 0.75 volt.—J. B. C. K.

*Copper, Quantitative Analysis of Commercial.* Hampe. Berg. u. Huttenm. Zeit. 1897, 56, 201 and 297.

*Estimation of Oxygen.*—In reply to Murnan (this Journal, 1897, 359) it is remarked that grease is best removed from copper shavings free from iron, by treatment, for a few moments, with boiling dilute caustic potash; there is then practically no oxidation. It is absolutely necessary to test the bulb-tubes at a high temperature, to ascertain whether their weight remains constant. The cuprous oxide is not at all evenly distributed in copper, and it is necessary to use 80–100 grms. of the metal taken from different parts of the bars, &c. The reduction of varieties of copper containing oxides of other metals besides cuprous oxide, offers no difficulty.

*Estimation of Cuprous Oxide.*—Thinly rolled, or finely filed copper is treated with cold dilute silver nitrate free from acid. The solution must not contain more than 60 per cent. of silver nitrate, and must be cooled to 0°, when the copper is added, and while the reaction is going on. It is filtered after 24–36 hours. There is no evolution of gas, the process being as follows:—

If the conditions are altered, there is an evolution of gas (nitric oxide):—

Dewey's equation is incorrect, since no nitrous acid could be detected in the solution.

*Estimation of Copper.*—With regard to the cuprous sulphide method, it is suggested that most of the copper should be precipitated electrolytically, and only the remainder determined as cuprous sulphide.—N. H. J. M.

*Mercuric Salts, Determination of Mercury in.* L. Vanino and F. Treubert. Ber. 30, [14], 1599–1601.

If hypophosphorous acid be added to a solution of mercuric chloride in sufficient quantity, the whole of the mercury is rapidly precipitated as calomel. If the acid be in excess, metallic mercury is precipitated; but this can be prevented by the previous addition of hydrogen peroxide.

To 10 c.c. of, say, a 6 per cent. solution of mercuric chloride, an equal bulk of hydrogen peroxide is added, and then hypophosphorous acid till precipitation is complete. The liquid is filtered through a weighed filter and the precipitate washed thoroughly, and dried at 100° C. In the case of mercuric nitrate, a much greater amount of hydrogen peroxide is requisite. This method is accurate, and possesses the great advantage over the precipitation as phosphate, of economy of time to the extent of several hours.—J. T. D.

*Colloidal Silver.* A. Lottermoser and E. von Meyer.

J. Prakt. Chem. 1897, 56, [17. 18], 2111.

See under XX., page 1035.

*Phosphoric Acid, Estimation of, by Titration of the Ammonium Phosphomolybdate Precipitate with Standard Alkali.* B. W. Kilgore. J. Amer. Chem. Soc. 1897, 19, 703—711.

THE principal objections raised against this method are, that it has not been tried on a sufficient variety of fertilisers and fertiliser materials; and secondly, the difficulty of washing the acid from the precipitates; it has also been noticed that a portion of the precipitate enters into solution. The first objection is disposed of by a series of results obtained by the author with the gravimetric and volumetric methods, which closely agree. A quantity of from 150 to 200 c.c. of water is generally enough to free the precipitates from acid, and it is when large volumes of water are used, that the molybdate precipitate passes through the filter mechanically.

The method was somewhat modified at the last meeting of the Association of Agricultural Chemists in order to avoid the excessive washing above referred to. The substance is, if necessary, incinerated to destroy organic matter, and 2 grms. are dissolved in nitro-hydrochloric acid and the volume made up to 200 c.c. For amounts of phosphate below 5, between 5 and 20, and above 20 per cent., 40, 20, and 10 c.c. respectively of this solution are taken, and 5 to 10 c.c. of strong nitric acid added. The solution is then nearly neutralised with ammonia, heated on the water-bath at 60°—65° C., 50 c.c. of freshly filtered molybdic solution added for each 0.1 gram of phosphorus pentoxide present, and then digested in a water-bath for 10 to 15 minutes. The clear liquid is quickly decanted into a Hirsch funnel and filtered with or without diminished pressure. The precipitate is washed by decanting twice with about 50 c.c. of nitric acid of 60 per cent., agitating, allowing to settle, and treating once with 50 c.c. of ammonium or potassium nitrate solution. The whole is then thrown on to the filter and washed with 150 to 250 c.c. of water. The filter and its contents are introduced into a beaker, excess of standard alkali and a few drops of phenolphthalein added, and the solution is titrated back with standard nitric acid.—J. L. B.

*Phosphates, Valuation of, according to the Amount of Citrate-soluble Phosphoric Acid in them.* P. Wagner. Chem. Zeit. 1897, 21, 905—911.

WHEN a freshly prepared citrate extract is stirred with alkaline citrate and magnesia mixture, the precipitate is quite free from silica, even in the case of highly silicious slags, and it is immaterial whether filtration is proceeded with at once, or after an interval of two hours.

The citrate extract of basic slag changes very slightly in appearance, if at all. When kept for a long time in a covered beaker, the extract does, however, undergo an important change, and solutions which have been kept for three hours, have a tendency to separate silica when alkaline citrate is added. An extract which had been kept for 24 hours, immediately yielded a gelatinous precipitate on addition of alkaline citrate. The separation of silica is much diminished by precipitating the phosphoric acid. When a citrate extract, three hours old, was treated with alkaline citrate, and stirred for half an hour, silica was precipitated. A similar solution, the same age, yielded, with alkaline citrate and magnesia mixture, a precipitate free from silica, and there was no separation of silica in the filtrate when kept for 24 hours.

The phosphoric acid in citrate solutions should therefore, be precipitated as soon as possible, but need not be filtered

immediately. Separation of silica from extracts which have been kept, may be avoided by adding the alkaline citrate and magnesia mixture simultaneously, instead of separately.

The citrate-magnesia mixture is prepared by dissolving citric acid (200 grms.) in 20 per cent. ammonia, and diluting to 1 litre with the same ammonia. The solution is then mixed with an equal bulk of magnesia mixture.

To estimate phosphoric acid, 50 c.c. of the extract (which should not have been kept for more than one hour) are treated with 50 c.c. of the citrate-magnesia mixture, stirred for half an hour and filtered at once, or, at any rate, within an hour. The analysis is then finished in the usual manner.

—N. H. J. M.

## ORGANIC CHEMISTRY.—QUALITATIVE.

*Sumac, Adulteration of.* W. Eitner. Der Gerber, 1897, 161.

THE examination of sumac as to purity is best carried out by means of the microscope. The leaves of *Rhus coriaria*, from which Sicilian sumac is obtained, are covered on both sides, but more particularly the obverse one, with a dense growth of very fine hair, of such a characteristic type as to render the detection of adulteration, even with any of the many other kinds of sumac, an easy matter.—C. O. W.

*Carbohydrates, the Identification of.* R. Sjöllema. Chem. Zeit. 1897, 21, [74], 739.

IT was previously known that, under certain circumstances glucose mixed with solutions of copper salts formed insoluble compounds on the addition of potassium or sodium hydroxide. Glucose gives such a compound with ammoniacal copper sulphate or copper acetate solutions; levulose, on the contrary, gives the precipitate only with the latter. In practice, a 10 per cent.  $\text{CuSO}_4$  solution is mixed with just sufficient ammonia to re-dissolve the cupric hydroxide, an excess being avoided because of its tendency to re-dissolve the expected sugar precipitate. About 30 c.c. of a 10 per cent. ammonia solution usually suffice for 100 c.c. of the copper liquor. Similarly, a 5 per cent. copper acetate solution is mixed with the exact quantity of ammonia required; in this case the presence of basic or even normal copper acetate necessitates the use of a little acetic acid. Neither of the solutions must smell very perceptibly of ammonia; and either must give a precipitate on dilution or on standing (a condition that is essential to success). The reagent is most satisfactory when it remains clear on the addition of five times, but becomes turbid with ten times its volume of water; and the exact limit of dilution permissible without turbidity, should be known, in order to guard against over-dilution by the sugar solution itself. On the other hand, the use of an excess of the reagent is to be avoided. With very dilute solutions the precipitate may not appear for several minutes or even for an hour, and in this case it is well to make a blank experiment with distilled water in equal volume and in lieu of sugar solution.

With a  $\frac{1}{2}$  per cent. solution of glucose, 2 c.c. mixed with  $\frac{1}{2}$  c.c. of the ammoniacal copper solution should become turbid at once, and should give a voluminous precipitate within a few minutes. In a mixture of glucose and levulose, the former is recognised by means of the ammoniacal copper sulphate, but the solutions must not be too concentrated. Experiments have not yet been tried to ascertain whether levulose may be detected in the solution from which the glucose precipitate had been obtained and filtered, or whether it would be possible to estimate or separate other carbohydrates by means of copper solutions. Small quantities (even 1 per cent.) of glucose may be detected in cane sugar with the aid of the ammoniacal copper sulphate, and levulose may be similarly detected by the acetate solution. Here, again, concentrated solutions hinder the reaction.

Milk sugar and galactose may give precipitates with copper solutions, the latter showing good results with the acetate, but not with the sulphate solution. Milk sugar gives no result with the sulphate, and not a good one with the acetate. An excess of ammonia is even more fatal to the detection of milk sugar than to that of the hexoses. An acetate and sulphate solution that gave good results with

glucose and levulose, was without effect on milk sugar solutions until 1 per cent. of acetic acid had been added, when it was rendered very suitable, enabling this sugar to be detected even in the presence of much cane sugar. Such a solution is an equally good reagent for glucose and levulose, but it is inconvenient owing to its tendency to become turbid on standing.—W. G. M.

*Linseed Oil, Amsel's "Water-Reaction" for.* W. Lippert. *Zeits. angew. Chem.* 1897, 655.

In this article the author gives fuller details of the experiments on which he has based his previous condemnation of Amsel's water reaction. He finds that the aqueous solution of a linseed soap is, and will remain, absolutely clear even in the presence of large amounts (5 or 6 per cent.) of lead, whether the metal has been added to the oil as oxide or as resinates; but that manganese in either form and in far smaller quantities (0.5 per cent. and upwards) causes a distinct opalescence, which appears, if not immediately, at least after a few minutes' standing, and which is proportionate in its intensity to the amount of manganese originally introduced. This turbidity is due to the precipitation of the metallic hydrate; and it does not occur in the case of lead, simply because lead hydrate is soluble in the excess of caustic alkali which is always present after saponification.

Turning to the possibility of detecting rosin, rosin oil, and mineral oil by means of this test, the author finds that a 2.5 per cent. litharge-varnish mixed with as much as 50 per cent. of rosin still gives a clear "water reaction;" and that, as might be expected from Coreil's work (this Journal 1892, 550), rosin oil can only be recognised with certainty when it forms some 15 per cent. of the total varnish. It is curious to note that, in presence of 20 per cent. of either pale or dark rosin oil, the soap solution is at first milky, but becomes clear after five minutes, and finally turns cloudy again in a few hours' time. Mineral oil also only causes a distinct turbidity when it amounts to about 30 per cent. of the oil under examination.—F. H. L.

*Cotton-Seed Oil, A Characteristic Reaction of.* G. Halphen. *J. Pharm. et de Chim.* 1897, 6, [9], 390—392.

COTTON-SEED oil, warmed with carbon bisulphide, gives a reddish coloration after some time. To adapt the reaction to analytical purposes, equal volumes of the oil under examination, of amyl alcohol, and of carbon bisulphide containing 1 per cent. of sulphur, are placed in a test tube heated on a boiling brine bath. If in 10—15 minutes a red or orange coloration appear, the presence of cotton-seed oil is proved. Should there be no coloration, i.e., of the same carbon bisulphide is added and the tube again warmed, and if the result be negative this is repeated. The coloration is not equally intense with all varieties of cotton-seed oil, but appears to depend to some extent on the process of refining to which the oil has been subjected. The reaction serves for the detection of 5 per cent. of the oil.—A. C. W.

*Formalin in Milk, Detection of, by means of Phloroglucinol.* M. Jorissen. *Bull. Soc. Chim.* 1897, 167; *Analyst*, 1897, [260], 282.

TEX c.c. of the milk are shaken with several drops of a 10 per cent. aqueous solution of phloroglucinol, and then a few drops of caustic soda or potash are added. A red coloration is produced with milk containing as little as 1 part of formalin in 20,000, whilst normal milk gives no reaction.—A. S.

*Oil of Star Anise, Adulterated with Petroleum.* J. C. Umney. *Chemist and Druggist*, 1897, 51, (913), 623.

In a recent importation of about 600 lb. of star anise oil, five cases were found to contain oil adulterated with petroleum. These had different specific gravities, ranging from 0.894 to 0.939, and the melting point, after congelation, varied from 5.7° C. to 11.5° C., the figures for the specific gravity of the genuine oil being not below 0.980, and the melting point not below 15° C. The petroleum was separated by charring the oil with strong sulphuric acid, when the undecomposed residue had a specific gravity of 0.835 at 15° C. The probable amount of petroleum present in the

oils would appear to vary from 47 to 56 per cent. In view of the advance in price of the oil and the active demand prevalent, importers should be on their guard against this form of adulteration.—J. O. B.

*Sesam. Oil, Some Substances in; and their Relation to the Characteristic Colour Reaction of the Oil.* V. Valla-vecchia and G. Fabris. *Ann. del Lab. Chim. centr. delle Gabelle*, 3, 13—26; *Chem. Centr.* 1897, [14], 772. (See also this Journal 1894, 69.)

The authors confirm the supposition that Baudouin's reaction for sesamé oil with hydrochloric acid and sugar is due to the furfural yielded by the latter; and they state that an intense red coloration is produced with sesamé oil by employing a 1 per cent. solution of furfural in 95 per cent. alcohol and hydrochloric acid. The substance in sesamé oil which is responsible for this colour reaction was isolated in the following manner:—A quantity of the oil was saponified with alcoholic potash, the alcohol evaporated off, and the soap dissolved in warm water and precipitated with barium chloride. The baryta soap was dried, exhausted with boiling alcohol, the alcoholic solution evaporated to dryness, and from the residue the following three substances were isolated:—(1.) Sesamin,  $(C_{18}H_{32}O_2)$ , which yields on treatment with nitric acid, two crystallisable compounds melting at 235° C. and 115° C. (2.) Higher alcohol  $(C_{27}H_{56}O + H_2O)$  crystallises from alcohol; melting point, 137.5° C.; does not give the furfural reaction, but forms an acetyl compound (melting point, 130—131°) insoluble in water, easily soluble in benzene. (3.) A thick odourless oil; easily soluble in alcohol, ether, chloroform, and acetic acid; slightly soluble in alkalis; insoluble in water and mineral acids. This compound is actually the cause of the furfural action.—A. S.

## ORGANIC CHEMISTRY.—QUANTITATIVE.

*Nitrogen Determination, Kjeldahl's; A Source of Error in.* B. Sjöllema. *Chem. Zeit.* 1897, 21, 740—741.

To prevent bumping in the distillation of the ammonia from the alkaline solution in the Kjeldahl process, it is generally recommended that some fragments of zinc should be placed in the solution. This is very advantageous; and in applying Jodlbauer's modification it is especially so, as it is ordinarily by no means certain that the ammonia will have been completely distilled over by the time that the bumping of the heavy saline solution commences. The author finds that there is a distinct amount of caustic soda or potash carried over mechanically during the distillation when zinc is employed, and hydrogen is, therefore, evolved if the ordinary bulb-tube (Fig. 1) be employed. This may

cause a variation in the result of 0.15—0.3 per cent. of N on 1 gram. of substance. By adopting a tube shaped as in Fig. 2, in which the inner tube is bent completely over, or as in Fig. 3, where the lower tube, outside, is bent into a Z-shape, the difficulty is avoided, and accurate results are obtained.—W. G. M.

*Fehling's Solution, False Results obtained with.* M. Z. Jovitschitsch. Ber. 30, [16], 2431—2432.

THE author's attention was called to the fact that Fehling's solution is frequently reduced by sulphuric, nitric, and hydrochloric acids, as well as by grape sugar, phenylhydrazine, hydroxylamine, &c., even although the reaction of the solution is so alkaline that litmus paper is coloured distinctly blue. The acids used were found to be chemically pure. If just sufficient of one of these mineral acids is added to 2—3 c.c. of freshly prepared Fehling's solution, so that red litmus paper is still coloured distinctly blue, then, on gentle warming, cuprous oxide is precipitated. The reduction may also take place in the cold, as the following experiment shows:—

A few drops of one of these mineral acids (not too strong) are added to 1—2 c.c. of strongly alkaline Fehling's solution until only a faint blue colour remains, i.e., until the solution becomes only faintly alkaline. On now adding a few more drops of the original Fehling's solution, an immediate turbidity sets in, and the reduction may then be completed by gentle warming.

The author concludes that mistakes may often arise with Fehling's solution, and emphasises the fact that it can only give trustworthy results in strongly alkaline solution.

According to the author, the above reduction, which often takes place spontaneously in Fehling's solution preserved in well-closed bottles, is due to a decomposition of the tartaric acid, even in alkaline solution.—J. S.

*Gases, Method of Collecting and Analysing the, in Canned Goods.* C. A. Doremus. J. Amer. Chem. Soc. 1897, 19, 733—735.

THE essential part of this apparatus consists of a bevelled hollow steel needle attached to the upper arm of an adjustable clamp. The point and lower part of the shaft are covered by a rubber stopper, which serves as a soft pad. The lower arm is moved along the body of the clamp until the can to be pierced, is held between the rubber stopper and the head of the screw, as shown in the figure. The upper portion of the needle is connected, by means of a capillary tube filled with water or mercury, with a receiver containing

either of these liquids. When the can is fixed within the apparatus, a few turns of the screw clamps it tightly between the rubber pad at the top and the screw below. The rubber yields to the pressure, making a tight joint around the needle. When the latter pierces the tin, the gases escape gently into the endiometer.—J. L. B.

*Calcium Carbide and Acetylene, Analysis of Commercial, and the Purification of the latter.* G. Lunge and E. Cedererentz. Zeits. angew. Chem. 1897, 651.

OWING to the irregularity in composition of all commercial

calcium carbide and the circumstance that it cannot be ground to powder in air without suffering some decomposition, in order to determine the amount of acetylene the carbide will evolve on treatment with water, it is necessary to operate on 50 (or better 100) grms. at a time. This involves the use of a gas-holder having a capacity of at least 40 litres; and the liquid employed as the "seal" should be a saturated solution of common salt, which, in very exact work, must be previously treated with acetylene to prevent any deficiency in the gas measured. If this is done, in reducing the volume of the gas to normal temperature and pressure, it is unnecessary for technical purposes to make any allowance for the vapour tension of the liquid; but if plain water has been used in the tank of the gas-holder, this correction must be carried out. The acetylene is most conveniently generated in an apparatus designed in such a manner as to cause the carbide to fall into the liquid (salt solution) by degrees; but the reverse process may be employed if desired.

The most serious impurity in commercial acetylene is phosphuretted hydrogen, which, like ammonia, appears to favour the formation of the explosive copper acetylide, and which also, if present in sufficient quantity, may render the gas spontaneously inflammable. The phosphuretted hydrogen is best determined by passing the gas as it is given off from the carbide through a solution of sodium hypochlorite, precipitating the phosphoric acid with magnesia mixture. If care be taken that all reagents are free from sulphuric acid, any sulphuretted hydrogen in the acetylene may be simultaneously estimated by acidifying the filtrate from the magnesia precipitate and then adding barium chloride. It should be observed, however, that the amount of sulphuretted hydrogen in different specimens of acetylene yielded by the same carbide, varies considerably according to the conditions obtaining at the time of preparation; and, moreover, the whole of the sulphur in the gas does not exist as hydrogen sulphide. Examined for phosphorus in this manner, two different samples of carbide evolved, as the mean of several tests, 0.1435 grm. (94.1 c.c.) and 0.338 grm. (222 c.c.) of phosphuretted hydrogen per kilo. respectively.

With suitable modifications the process becomes available for the purification of commercial acetylene. The hypochlorite is used in its original form of bleaching-powder, and it is preferably moistened with only sufficient water to make it cohere into balls. In this case the gas must be well cooled before it passes into the purifier, in order that it may not carry too much moisture with it; or it may be dried and freed from ammonia by treatment with sulphuric acid of sp. gr. 1.6 to 1.7, which does not act on the hydrocarbon itself. After the chloride of lime purifier, a vessel containing lime should be employed, so that any solid or gaseous chlorine compounds may be retained.—F. H. L.

*Oils and Fats, Animal and Vegetable; Purity of Commercial.* D. Holde. Chem. Rev. Fett- u. Harz-Ind. 4, [20], 271—276.

IN determining the iodine number it has been found advisable at the Charlottenburg Versuchsanstalt to allow the iodine solution to act on the liquid fats for 24 hours, with exclusion of light, the results being more uniform than can be obtained by the ordinary two hours' reaction. By this means the differences between the values given by the Hübl and the Waller solution are in most cases reduced to about three units. In the case of Japanese wood oil, however, the difference amounts to 17 units, and consequently it is considered that the use of Waller's reagent should be restricted to such oils as are found, by sufficiently comprehensive experience, to give concordant results with both methods.

Out of 25 samples of fats and oils examined, four were found to be adulterated, three of them seriously.

A so-called "linseed-oil varnish," found in practical use to be deficient in drying properties, proved to be merely raw linseed oil, requiring four days to dry properly. A "spermaceti oil" consisted almost entirely of porpoise oil, and a specimen of "fuller's grease" was found to contain 88 per cent. of unsaponifiable bituminous oil.—C. S.

**Unsaponifiable Oil in Greases with a Lime Base, Determination of.** H. Bailey. Chem. News, 1897, 76, 171.

The author failed to obtain satisfactory results with the ordinary method—complete saponification with caustic alkali and extracting the unsaponified oil from the dried soap with a suitable solvent—of determining unsaponifiable oil in greases with a lime base, as prolonged drying was necessary to free the soap from water, and it was difficult to completely extract the unsaponified oil from the pulpy mass.

The following method is recommended as giving accurate results and requiring less time than the ordinary process:—10 grms. of the sample are boiled, with constant stirring, with dilute hydrochloric acid, until the grease is completely decomposed and free from lumps. The oils and fatty acids are filtered off, and the residue is thoroughly washed with boiling water. The filter paper is now broken, the liquid oil washed through by a jet of boiling water, and a concentrated solution of 2 grms. of caustic potash added, together with a little alcohol, after which the solution is heated, with constant stirring, until saponification is complete, preferably with the addition of a little more alcohol to replace that lost by evaporation. Most of the alcohol is evaporated off, about 100 c.c. of water added, and the mixture warmed until clear. Then, after cooling, 30 c.c. of methylated ether or petroleum spirit are added, and the mixture well shaken and allowed to stand. The soap solution is drawn off, and the ethereal layer washed two or three times with water, the washings being added to the soap solution. The soap solution is then shaken with 20 c.c. of ether to remove any traces of oil, and the washed ethereal solution transferred, together with the first ethereal solution, to a small, tared flask with wide mouth. The ether

is evaporated off and the residue of oil dried in a air-bath at a temperature of a little over 100° C. until of constant weight.—A. S.

**Proteid and Gelatinoid Substances, Improved Method of Determining.** A. B. Allen and A. B. Searle. Analyst, 1897, [259], 258–263. (See also Analyst, 1897, 228.)

A quantity of the solution containing about 1 gram of the albuminoid matter, is made up to about 100 c.c. with water, and acidified with hydrochloric acid. Bromine is then added in considerable excess, and the liquid stirred vigorously for some time. The whole is allowed to stand for half an hour, or until the precipitate has settled, and the liquid is then decanted through an asbestos filter (a cylindrical funnel containing a little glass wool covered with a pad of pulped asbestos). The precipitate adhering to the beaker is washed several times with cold water, and the washings poured through the filter. When most of the free bromine has been washed out of the precipitate, the liquid may not run clear, and it is therefore advisable to keep the washings separate from the filtrate, and, if necessary, to wash with sodium sulphate solution or with bromine water. The contents of the filter tube are returned to the beaker in which the precipitation was effected, and the nitrogen in the precipitate estimated by the Gunning-Kjeldahl process. It was found that the precipitates produced by bromine in solutions of the proteids are insoluble in water and in dilute hydrochloric acid; but that the extractive matters of meat are only precipitated in concentrated solutions, the precipitates formed being in great part dissolved on dilution, especially in presence of a little hydrochloric acid. The following table gives the results obtained by this method with various proteid and gelatinoid bodies:—

Substance.	Nitrogen per Cent.		Nitrogen multiplied by Factor.		Factor.
	Total in Original Substance.	Precipitated by Bromine.	Total in Original Substance.	Precipitated by Bromine.	
Commercial gelatin .....	11.10	14.00	77.50	77.00	5.5
Gelatin-peptone .....	11.10	13.90	77.50	76.5	
Commercial seale albumin .....	8.80	8.72	55.80	55.2	
Syntonin from seale albumin .....	9.86	(9.76) (9.69) (9.60)	62.41	(61.78) (61.34) (60.77)	6.33
Digested seale albumin .....	8.80	8.81	55.30	55.80	
Fresh white of egg .....	1.80	1.88	11.26	11.20	
Syntonin from white of egg .....	1.80	1.80	11.26	11.26	
Peptone from white of egg .....	0.70	0.60	4.37	4.37	
Beef extractives .....	0.33	0.004	2.11	0.03	

It is suggested that, by saturating the liquid with zinc sulphate and treating the filtrate with bromine, the real peptone formed in digestion experiments might probably be determined with accuracy. It was found, on applying this method, that Liebig Company's meat extract does not contain any considerable quantities of real peptones.—A. S.

**Beeswax, Examination of.** K. Dieterich. Chem. Rev. Fett-u. Harz-Ind. 4, [19], 259–263.

In comparing the hot and cold methods for determining the acid number, the ester number, and saponification value, and the ratio number, the author obtained the following average figures in a number of samples of pure yellow wax:—

—	Acid Number.	Ester Number.	Saponification Value.	Ratio.
Hot method .....	20.07	76.30	95.00	1:3.3
Cold " .....	19.37	70.07	90.80	1:3.6

and concludes that the lower values yielded by the cold method are the more reliable of the two, since the lower temperature employed, precludes the possibility of error arising from the formation of decomposition products. The cold method is said to be equally efficient with the hot method

in the detection of adulteration, and the results of the examination of several adulterated samples are supplied in the paper.

In a note, Henriques states that he has never noticed the above-mentioned differences yielded by the two methods when applied to beeswax, and only found decompositions occur in the case of bodies (e.g., wool-fat, Chinese insect wax) containing a large proportion of unsaturated alcohols.—C. S.

**Ethyl Alcohol, Highly Diluted [1 in 3,000 to 1 in 10,000]: Distillation of.** Nieloux and Baudner. Analyst, 1897, [259], 263; Ann. de Chim. Anal. 2, [11], 202–204.

It has been found that on distilling dilute solutions of alcohol, the percentage of alcohol coming over is in inverse ratio to the concentration of the solution. Thus, with mixtures of alcohol and water from 1 in 500 up to 1 in 1,000, the whole of the alcohol is not over when one-third of the solution has been distilled off, but when the concentration is below 1 in 3,000, the whole of the alcohol is obtained in the distillate, when the latter amounts to one-fourth of the original volume of the solution. The alcohol may be estimated by the Nieloux bichromate method by adding a solution of potassium bichromate (19 grms. per litre) and 4–5 c.c. of pure concentrated sulphuric acid, and then comparing the colour with standard samples containing known quantities of alcohol.—A. S.

*Spirits, Estimation of the Higher Alcohols in.* X. Roques. *Analyst*, 1897, **22**, [259], 263; *Ann. de Chim. Analyt.* **2**, [8], 141—146.

THE author has improved the ordinary method of heating the alcohol with sulphuric acid and determining the amount of coloration produced, in that he first fixes the aldehydes by means of an amine. 100 c.c. of the sample, previously distilled and adjusted so as to contain 50 per cent. of alcohol, are boiled gently for an hour with 2 grms. of *m*-phenylenediamine chloride and a few granules of pumice in a flask fitted with a reflux condenser. The mixture is cooled and then distilled, care being taken that no spray passes over during distillation. The operation should be completed in 40 minutes, and the condenser must be long enough (40 ins.) to cool the distillate to the ordinary temperature. 75 c.c. of distillate are collected; this volume contains the whole of the alcohol, and is consequently of 66·7 per cent. strength. 10 c.c. of the distillate are taken, 10 c.c. of pure, colourless sulphuric acid monohydrate added, the mixture shaken, heated for an hour in a brine-bath boiling at 120° C., and compared with a standard solution of 0·667 gm. of isobutyl alcohol per litre, of 66·7 per cent. alcohol (corresponding to 0·5 gm. per litre of 50 per cent. alcohol), prepared and treated in a similar manner. The comparison is made on the cooled liquids in a Dubose colorimeter, the amount of higher alcohols (per litre of 50 per cent. alcohol) being found and expressed as isobutyl alcohol by means of the formula  $\frac{500 \times H}{H_1}$ , where

$H$  = the stratum of the standard liquid, and  $H_1$  that of the sample. The depth of colour is not exactly proportional to the quantity of the higher alcohols present, the variation between the apparent and actual amounts being as follows:—

Apparent.	Actual.	Apparent.	Actual.	Apparent.	Actual.
1·125	1·000	0·760	0·700	0·379	0·400
1·009	0·900	0·640	0·600	0·255	0·300
0·886	0·800	0·500	0·500	0·150	0·200
..	..	..	..	0·060	0·100
..	..	..	..	0·019	0·050

The delicacy of the reaction is nearly twice as great with the above method, employing 66·7 per cent. alcohol, as in the ordinary method with 50 per cent. alcohol. Several readings should be made in the colorimetric estimation—two with a 10 mm. and two with a 20 mm. stratum—and the mean of the results taken. If the amount of higher alcohols be more than 1 gm. per litre of 50 per cent. alcohol, the sample should be suitably diluted with pure 66·7 per cent. alcohol after, or with 50 per cent. before, being distilled. The method is stated to give constant though not absolute results.—A. S.

*Alcohols, Analysis of.* E. Barbet. *Bull. Assoc. Chim.* 1897, **15**, [3], 250—252.

PHENOL and sulphuric acid in presence of aldehydes, give a violet coloration; thymol and sulphuric acid give a greenish coloration and coloured compounds with higher alcohols. In view of the fact that quantitative methods based on these reactions have been proposed, the author has experimented, and finds that the phenols act only on the aldehydes, and that this action is so variable, according to the nature of the aldehyde, that no quantitative estimation can be based on it. A mixture of 1 per cent. of pure amyl alcohol and pure isobutyl alcohol in ethyl alcohol, equally pure, although of bad flavour, gave no indication with either thymol, naphthol, or hydroquinone.—L. J. de W.

*Wine, Determination of Glycerin in.* C. Boettinger. *Chem. Zeit.* 1897, **21**, [67], 658—659.

THE method proposed depends upon the conversion of the glycerin into its acetyl derivative, which can then be weighed. The operation is carried out as follows:—About 1 gm. of hydrogen potassium sulphate is put into a small stoppered bottle, and this, with contents, is carefully weighed; the substance to be treated is next introduced,

and the whole again weighed; pure acetic anhydride (1—1·5 c.c.) is then added, the bottle is closed, gently shaken, and heated in a water-oven for two hours. The product is treated, when cold, with a few drops of alcohol, and extracted with ether, the ethereal extract being afterwards evaporated in a weighed beaker, and the residue dried at 105°. The author does not regard this method as finally settling the difficult question of the determination of glycerin in wine, but he believes it to be a step in the right direction, and suggests that possibly the formation of some other ethereal derivative of glycerin may prove still more simple.

—A. K. M.

*Gutta-Percha.* J. A. Montpellier. *Rev. de Chim. Indust.* 1897, **8**, [94], 300—302.

THE author here concludes his account (this Journal, 1897, 925) of gutta-percha, and gives the following scheme for its analysis:—

*Estimation of Gutta and Resins.*—From 0·5 to 1 gm. of the finely divided sample is placed in a weighed filter-paper, supported by a perforated platinum cone, which is suspended (its point in the liquid) in a flask connected with a Soxhlet apparatus. Here it is extracted with boiling alcohol for five or six hours, after which the cone is transferred to the Soxhlet extractor, and the extraction continued for the same period. The resins (fluavile and albane) dissolve in the boiling alcohol, whilst the gutta and impurities remain in the filter-paper, and are dried at 100° C. in a current of carbon dioxide, and weighed. The impurities are determined in a separate estimation and deducted.

*Separation of Albane and Fluavile.*—This can only be done incompletely, but an approximate determination of the amount of each may be made by extracting 5 grms. of the sample with alcohol, as above, and evaporating the alcoholic extract until the albane begins to separate out. On cooling, the fluavile remains in solution, and the albane, which has crystallised out, is collected on a weighed filter, dried at a low temperature, and weighed.

*Estimation of Water.*—One gm. of the gutta-percha is dried at 100°—110° in a current of carbon dioxide for six or seven hours.

*Estimation of Impurities.*—A weighed quantity (not exceeding 1 gm.) is extracted with boiling chloroform in the same way as in the determination of the gutta with alcohol. This dissolves both gutta and resins, and the impurities left behind are dried in a current of carbon dioxide and weighed.

*Ash.*—This is determined in the usual manner. Its amount never exceeds 0·5 per cent.

With regard to the water in gutta-percha, the author finds that although at first it lowers the insulating power of the latter, this is only temporary, and the greater the amount of water, the sooner the gutta-percha oxidises on exposure to the air.—C. A. M.

*Starch Products, The Exact Estimation of Total Carbohydrates in Acid-hydrolysed.* G. W. Rolfe and W. A. Faxon. *J. Amer. Chem. Soc.* 1897, **19**, 698—703.

AN attempt has previously been made by one of the authors (this Journal, 1897, 167) to ascertain the factor to be employed for deducing the solid matter from the specific gravity of any starch product hydrolysed by means of acid. The authors have now endeavoured to confirm these calculated factors by the actual determination of the total solids in a number of representative acid-hydrolysed starch products. For this purpose an apparatus has been devised, which permits of the major bulk of water being removed before coming into contact with the drying agent, and avoiding evaporation on a water-bath.

The tared beaker containing the solution to be evaporated is slipped on the end of the adapter, an air-tight joint being made with "bill-tie" tubing. By the three-way stop cock, communication can be made with the vacuum pump, and with a 250 c.c. flask containing phosphorus pentoxide; or either can be shut off.

The method of drying is as follows:—The cock is opened to the pump only, and the air exhausted to 680—690 mm.,

the beaker being then lowered into an oil-bath and heated to about 100° C. until most of the water is evaporated.

Communication is made with the pentoxide flask, and the residue dried to constant weight at 120° C.

The results were tabulated and plotted. They form a straight line, which is very slightly higher than the line calculated by using the revised carbohydrate values of Brown, Morris, and Millar (this Journal, 1897, 165). Within the specific gravities 1.035 and 1.045, the authors can calculate the absolute specific gravity influence of any acid hydrolysed starch solution by the equation  $\Sigma = 0.001023 - 0.00001329(195 - [\alpha]_D)$  when the specific rotatory power (obtained by the factor 0.00386) is known. For commercial glucoses, the factor 0.00393 is sufficiently exact for most determinations.—J. L. B.

#### Formaldehyde, Vaporised, for Disinfecting Purposes; Estimation of. P. Strüver. Zeits. Hyg. 1897, 25, 357.

THE gases evolved by the lamp, or aliquot portions of the air of the chamber, in which formaldehyde is being volatilised, are passed through two washing flasks containing water, and a third vessel filled with ammonia to act as a check. At the end of the test the latter is treated with silver nitrate, in order to see if any formaldehyde has escaped the water, and, if not, excess of standard ammonia is added to the contents of the first two flasks, and the liquid allowed to rest for 24 hours. It is then titrated with decinormal oxalic acid, or evaporated to dryness and the hexamethylene-amine weighed. The reaction is as follows:  $-6\text{CH}_2\text{O} + 4\text{NH}_3 = (\text{CH}_2)_6\text{N}_4 + 6\text{H}_2\text{O}$ .—F. H. L.

#### Observations [and Analytical Methods used] in the case of some of the Chemical Substances in the Trunks of Trees. E. H. Storck. Bull. Bussey Inst. 1897, 2, 386.

THE author, after a brief discussion of the broad physiological problem, passes to the record of experimental results, with critical notes upon the analytical methods employed. The main value of the paper is as a contribution to the methods of the agricultural laboratory.

The following are the more important experimental numbers obtained:—

#### Percentage of Pentosans (= Furfural $\times 1.84$ ) present in the Wood of Grey Birch (*Betula populifolia*) at different Seasons.

	Inner Wood.	Outer Wood.	Bark.
May .....	39.2	36.1	30.8
July .....	(1) 30.5 (2) 30.6	34.7	21.1
October .....	29.8	30.0	22.7

#### Percentage of Starch in same Wood and at the same Periods.

May .....	4.9	5.4	7.7
July .....	3.8	3.9	7.5
October .....	3.8	3.5	4.2

The above determinations were made by the "maltng" process recommended by Wiley (Agricultural Analysis, v. 3, 1900), and include any (small) proportion of readily formed sugars present in the wood. Methods based upon acid hydrolysis followed by estimation of empic reduction were critically investigated, the numbers obtained showing the hemicelluloses and pentosans to be considerably attacked. In the following tables the empic reduction is calculated to pentosan in the case of the woods and to hexosans for the substances poor in pentosans.

#### Hydrolysis by the Acid of 2.5 per Cent. HCl, 5 hours' Digestion at 90°—100° (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> Production calculated as stated.)

	Inner Wood.	Outer Wood.	Bark.
Grey birch—May .....	22.0	27.2	23.0
" July .....	22.7	22.2	21.5
" Oct. ....	21.9	(1) 24.5 (2) 23.8	28.0
Alder (Jan.) .....	25.1	25.6	26.1
Sugar maple Oct. ....	19.6	20.5	..
White pine .....	..	12.2	..
Apricot stones .....	..	23.5	..
Peach .....	..	20.8	..
Ivory nut .....	..	22.3	..
Date stones .....	..	25.0	..

The same series of specimens were then treated under less severe conditions, *viz.* boiled with an acid of 1 per cent. HCl strength for one hour, and the soluble products similarly estimated. The proportions converted were approximately one-half of those of the above table.

It will be seen, by comparing the numbers in the above table for grey birch with the preceding table giving total pentosans in the same wood, that the hydrolysis of the pentosans, even with the stronger acid, is still only partial. A number of determinations of furfural in the residues from the hydrolytic treatments, confirmed these figures, showing a considerable proportion of "furfuroils" remaining, *i.e.*, resisting the hydrolysis. The subjoined table comprises a typical selection of results:—

#### Percentage of Furfural calculated to Original Dry Substance.

	Original.	From Residues of Action of	
		HCl, 2.5 per Cent.	HCl, 1 per Cent.
Grey birch-bark, cut in May .....	16.7	6.5	..
" " July .....	14.4	6.1	..
" outer wood (July) ....	18.8	8.6	12.9
" inner wood " ....	16.6	8.0	..
Sugar maple, outer wood (Oct.) .....	18.2	4.9	..
" inner wood .....	20.9	6.4	..
Alder, outer wood .....	16.9	..	6.7
Date stones .....	9.6	4.3	3.4
Apricot " .....	18.4	6.9	12.8
Peach " .....	15.0	7.6	8.7

The author next endeavoured to estimate the proportion of wood-gum obtainable from a selection of the specimens above investigated, using the process of solution in cold alkaline lye, and precipitation by acids in presence of alcohol. The following percentages were obtained:—

	Inner Wood.	Outer Wood.	Bark.
Grey birch—May .....	14.3	14.4	..
" Oct. ....	13.1	13.5	..
Sugar maple .....	..	..	4.5
Alder Jan. ....	10.4	15.0	11.8

But little value is attached to these numbers by the author as the substances so isolated are undoubtedly mixtures.

In conclusion, the paper contains the results of determination of "crude fibre" (Weende method) and cellulose by the method of "fusion" with alkaline hydrate (Lange's method). The imperfections of both methods are discussed and admitted.—C. F. C.

*Menthol in Peppermint Oil, A Rapid Method of Approximately Estimating.* C. Kleber. Pharm. Review, 1897, 15, 135; through Semi-Annual Rep. of Schimmel and Co., Oct. 1897, 45.

ABOUT 5 grms. of the oil, accurately weighed, are mixed in a flask, furnished with an accurately fitting condenser, with about 5 c.c., carefully measured, of acetic anhydride, and boiled for 30 minutes. In the meanwhile, an equal quantity of the same acetic anhydride is titrated with normal soda solution and phenolphthalein. After cooling the boiled liquid, water is added, and the condenser carefully washed; the whole aqueous solution is then titrated with normal soda. The difference in the number of c.c.'s in the two titrations, multiplied by 0.156, gives the amount of menthol in the oil taken. The disadvantages of this method are the relatively large volume of normal solution used in the titration, and the fact that the required number has to be found by difference in two experiments, which necessarily makes the method less exact; it has the advantage that all the operations can be performed in 50 minutes.

—J. O. B.

*Clove Oil.* E. Erdmann. J. Prakt. Chem. 1897, 56, 143—156.

On treating clove oil with warm or cold potash, an oily residue is left, which contains oxygen. The boiling point of this substance, freed from eugenol, varies as much as that of clove oil itself, but its specific gravity is lower. The addition of concentrated potash causes a partial crystalline solidification. If the treatment of the residue with potash be repeated, the specific gravity falls further, and approaches that of pure caryophyllene, but, even after continued shaking with concentrated aqueous potash, the oil still contains oxygen, though the substance containing it is removed after a short treatment with alcoholic potash. Clove-stalk oil on treatment with cold aqueous potash leaves only sesquiterpenes. The author found the oxygen-containing substance to be eugenol, and proved that for the most part it was contained in the higher boiling fractions of the clove oil.

The terpene obtained on saponifying clove oil with alcoholic potash, diluting with water, and extracting the phenol with ether, consists of pure caryophyllene, but the great variation in the boiling point of the oily residue from the clove oil, referred to above, is due, not to caryophyllene, but to the acetegenol.

In Thom's method of valuing clove oil (Verband. der Gesell. deutsch. Naturf. u. Aerzte, 1891, 184) by determining the amount of eugenol, the latter is converted into benzoyl eugenol, and estimated as such. The author points out that this method is based on the assumption that only free eugenol is present, and shows that none, or only a trifling amount, of the acetegenol is determined, and that higher results are obtained by previously saponifying the oil completely. After the free eugenol has been determined in the usual way, 5 grms. of the clove oil are saponified by heating over the naked flame for three minutes with 11 grms. of soda-lye (29 per cent. NaOH), after which 10 c.c. of water are added, and the estimation finished as in Thom's method. (Alcoholic potash must not be used in the saponification, or esters will be formed.) In this way, the following results were obtained:—

	Thom's Method.	Total Eugenol.
Clove oil A. ....	83.96	85.68
" " B. ....	82.97	84.84
" " C. ....	82.77	
" " D. ....	80.29	81.90

The difference in these figures corresponds to a percentage of acetegenol in the oil of from 2.1 to 2.6 per cent.

Specimens of clove stalk oil were found to contain no acetegenol, and this appears to be a point of difference between the two oils.

On saponifying clove oil with alcoholic potash and titrating the free acid, the result shows a greater amount than corresponds to the acetegenol as determined above. This difference and the fact that in Thom's method a certain amount of saponification takes place, shows that other compounds must be present. Of these the author detected salicylic acid, but in much smaller quantity than the acetic acid. He considers it probable that the hydroxyl group of the salicylic acid is replaced by acetyl, and that the acetylsalicylic acid forms an ester with the eugenol.

These constituents have but little influence on the odour of clove oil, which is derived from substances in the fractions of lower boiling point. Acet-salicylic-aldehyde was not detected, but furfural was extracted and also identified by the xylydine reaction, the vapour from the oil giving an intense red when brought into contact with filter paper moistened with a mixture of *m*-xylydine and glacial acetic acid, or with aniline acetate. (See Schimmel, this Journal, 1897, 557.) A still more sensitive reaction for furfural is given by a solution of 5 grms. of  $\beta$ -naphthylamine in 20 c.c. of glacial acetic acid, the test being applied by placing several drops on filter paper and adding a drop of the liquid to be tested. Strong furfural solutions give an intense purple colour. Dilute aqueous solutions (1:10,000) give the reaction strongly, and it is still recognisable in solutions of 1 in 100,000. By means of this reaction furfural can be detected in cigar smoke. Both clove oil and clove-stalk oil give an intense purple colour.

Characteristic colours are also given by other aldehydes. Citral turns a reddish yellow; salicylic aldehyde and anisaldehyde, a yellow; formaldehyde, propylaldehyde, and valeric aldehyde, extremely faint yellow; acetaldehyde and crotonaldehyde, a somewhat stronger brownish yellow. A yellow colour is also obtained with eugenol.

With regard to the presence of other bodies in clove oil, it is probable that eugenol is not the only phenol in the higher boiling fractions, for the variation in the boiling point of crude eugenol shows that it is not a simple substance, and on distilling crude eugenol with steam, the author obtained a residue of a phenol-like character.

—C. A. M.

## XXIV.—SCIENTIFIC & TECHNICAL NOTES.

*Phosphorescent Strontium Sulphides, Stability of.* J. R. Mourelo. Comptes Rend. 125, 462—464. (See also this Journal, 1897, 642.)

By exposing samples of phosphorescent strontium sulphide, prepared by various methods, to the combined influence of air and sunlight at 45° C. for three hours, the author found that all undergo more or less decomposition with liberation of hydrogen sulphide and partial oxidation. Impurities, and especially those of an alkaline nature, increase the intensity of the phosphorescence and also, by retarding oxidation, greatly affect the stability of the sulphide. The phosphorescent monosulphide, like the sulphides of the alkalis and alkaline earths, is unstable owing to its tendency to form polysulphides, sulphate, and hydrosulphides. Such decomposition diminishes the phosphorescence only in proportion to the amount of sulphide destroyed and the production of non-phosphorescent compounds.—E. W. W.

*Strontium Sulphide, Production of, by the Action of Sulphuretted Hydrogen on Strontium Oxide or Carbonate.* J. R. Mourelo. Comptes Rend. 1897, 125, [20], 775—777.

When sulphuretted hydrogen is passed over strontia or strontium carbonate heated to bright redness in a porcelain tube, strontium sulphide, SrS, is left as a white granular mass, without smell, but decomposed by moisture. If the temperature be not high enough, water condenses in the

porcelain tube, the inverse reaction takes place, and strontium hydrosulphide and hydrate are obtained as secondary products. The sulphide produced according to this method is not phosphorescent, but becomes so on oxidation at a high temperature.—A. C. W.

*Sulphuric Acid, Action of Hydrogen on.* Berthelot.

Comptes Rend. 1897, 125, [20], 743-746.

SULPHURIC acid is constantly employed for drying hydrogen gas, several atomic weight determinations depend on the results of reducing oxides in hydrogen thus dried. If 0.5 gram. of sulphuric acid (boiled), be heated in a sealed tube at 250° C. for six hours with 11 c.c. of hydrogen, all the gas is absorbed.  $\text{H}_2\text{SO}_4 + \text{H}_2 = \text{SO}_2 + 2\text{H}_2\text{O}$ . A slow current of hydrogen may be passed through the acid for an hour at the ordinary temperature, without the production of an appreciable quantity of sulphur dioxide, but if the contact be prolonged, as for example, in a sealed tube for two months, 75 per cent. of the hydrogen is absorbed. Light has no noticeable effect on the reaction.

If oxygen be also present, the same volume of hydrogen is absorbed, and also some oxygen, but the oxidation of the sulphur dioxide by oxygen appears to proceed more slowly than the reduction of the acid by hydrogen. This is the case at the ordinary temperature or at 250° C. The sulphur dioxide acted upon, is that dissolved in the acid, rather than the gaseous part, for a mixture of hydrogen, oxygen, and sulphur dioxide heated to 100° C. for 24 hours suffered no diminution in volume, though at 250° C., some of the oxygen had combined. Hydrated nitric acid,  $\text{HNO}_3 + 2\text{H}_2\text{O}$ , is not attacked by hydrogen at the ordinary temperature or at 100° C.—A. C. W.

*Sodium Iodide.* J. C. Umney. Pharm. Journ. 1897, 59, [1424], 312.

THE requirements of the official test for sodium iodide in the British Pharmacopœia require that the substance shall contain 99 per cent. of anhydrous salt, while the directions for its preparation are considered by the author to favour the formation of both the anhydrous salt, crystallising out above 20° C. and the hydrated crystals containing 2 mols.  $\text{H}_2\text{O}$ , which form below that temperature. The German and United States Pharmacopœias recognise this difficulty by requiring the official salt to contain at least 95 per cent. NaI.

A recent examination of commercial samples shows that none approach the official requirements: the amount of NaI present in them ranging from 81 to 91 per cent. It is suggested that, if it be impossible to obtain the anhydrous salt on the commercial scale, a definite statement to that effect should be made, with a view to modifying the requirements of the official test.—J. O. B.

*Evolution of Oxygen during Processes of Reduction.* K. Frenzel, S. Fritz, and V. Meyer. Ber. 30, [16], 2515-2519.

IN former communications (Ber. 29, 2549 and 2828; also 30, 1935) it was shown that hydrogen and carbon monoxide were slowly but completely absorbed by neutral or alkaline solutions of potassium permanganate. On agitating the gas, however, with acidified permanganate solution, the oxidation was also found to be complete, but there was at the same time a considerable quantity of free oxygen evolved.

It has been suggested by Erdmann (Annalen, 294, 68) that the liberation of oxygen was due to the transitory formation of hydrogen peroxide.

The authors have therefore tried the action of air, hydrogen, carbon monoxide, and carbon dioxide on the following oxidising agents in the dry state, and when necessary at a high temperature:—Potassium permanganate, silver oxide, potassium peroxide, lead peroxide, and barium peroxide. In this way the possible intermediate formation of hydrogen peroxide is excluded. In nearly all cases free oxygen was obtained although the oxidising agent was not heated up to the temperature at which it decomposes.

The apparatus used and the results obtained are given in tabular form.

Potassium peroxide which does not evolve oxygen at the melting point of glass, gives off oxygen when treated with carbon monoxide, carbon dioxide and hydrogen, at the temperature of boiling sulphur.

The formation of the oxygen is explained by the following equations:—

Silver peroxide and potassium permanganate when heated below their decomposition temperatures also liberate oxygen.

During the reaction a rise of temperature, and occasionally ignition, take place, and the heat developed in this case is sufficient to evolve oxygen by heating the substance above its ordinary temperature of decomposition.—J. S.

*Mercury, Direct Action of Sulphuric Acid upon, at the Ordinary Temperature.* Berthelot. Comptes Rend. 1897, 125, [20], 749-750.

SULPHURIC acid brought to its maximum concentration point by boiling, attacks mercury at the ordinary temperature, but without any visible escape of gas. The acid contains mercuric sulphate, and gives up sulphurous acid to a stream of carbon dioxide. A trace of black mercuric sulphide is also formed. The reaction is not to be attributed to foreign metals. The mercury used was very pure, and the phenomenon was repeated when three successive quantities of acid were used with the same sample of mercury. A small percentage of water prevents the reaction.

—A. C. W.

*Phosphorus, A Plant Constituent containing, which on Decomposition yields Inositol.* L. Winterstein. Ber. 1897, 30, 2299-2302.

E. SCHULZE and the author (Zeits. J. Physiol. Chem., 22, 90) have described a constituent of plant seeds containing phosphorus, which was extracted by a 10 per cent. solution of sodium chloride; the compound could be regarded as a calcium-magnesium salt of combined phosphoric acid. The author has investigated the nature of the organic compound in combination with the phosphoric acid, and for that purpose he treated the powdered seeds of *Sinapis alba* (previously freed from fat) with dilute acetic acid. The extract was carefully purified and isolated as a white amorphous mass. To study its decomposition, the calcium was removed by oxalic acid and the magnesium salt decomposed with fuming hydrogen chloride in a sealed tube at 130-140° C. From this product, inositol was separated.—J. L. B.

*Fermentation of Green Grass, Chemical and Bacteriological Investigation of.* O. Emmertling. Ber. 1897, 30, [14], 1869-1870.

THE moist grass was pressed into an earthenware jar the tightly fitting lid of which carried a thermometer and tube to convey the gases evolved. The composition of the grass calculated on the dry substance, is given in the following table:—

	Fresh Grass.	After Four Weeks.
	Per Cent.	Per Cent.
Wood fibre .....	26.40	31.36
Ether extract .....	1.86	3.24
Protein .....	11.80	9.13
Ash .....	7.62	8.14
Nitrogen extract .....	32.32	48.13

The temperature rose after 24 hours, through 26° C., remained constant for some time, and then slowly fell to the temperature of the room. A small but steady evolution of gas took place, this contained 64 per cent. of carbonic acid and 36 per cent. of nitrogen. No methane was found.

The figures given, show that the nitrogen free extract (carbohydrates chiefly), and the protein, decreased, whilst the cellulose, contrary to general opinion, was not attacked. The increase in ether extract is caused by the formation of

organic acids. A small quantity of quinone was isolated from the fermented grass, this was probably formed by the oxidising action of the oxygen enclosed with the grass. In a second experiment, where air was replaced by carbonic acid, no quinone was detected, and much less fermentation took place.

Bacteriological investigation revealed the presence of traces of moulds, chiefly *mucor*; among bacteria, besides *L. bacilli* mostly as spores, *granulobacteria*, several coccii, and in abundance *B. mycoides*. This last is known to energetically decompose albumin, the author also finds that it produces appreciable quantities of lactic acid from glucose, and forms acids from arabinose and xylose, it hydrolyses starch by means of an enzyme. Other lactic acid bacteria could not be found, thus the albumin decomposition and acid formation, must at least in part be attributed to *B. mycoides*.—A. C. W.

*Sugar, On the Speed of Reduction of Ferric Alum by.* J. H. Long. J. Amer. Chem. Soc. 1897, 19, 683—698.

THE author has previously found (this Journal, 1896, 550 and 663) that certain salts invert cane sugar with simultaneous reduction or other change. When a solution consisting of ferric alum and cane sugar was exposed to the light for six months, the former substance was completely reduced. Attempts were made to measure the rate of reduction of the ferric salt by the change of colour during the reaction, without, however, satisfactory results. If a direct reduction of the ferric salt is brought about by the sugar, the change is one that should easily be followed by a series of electrical conductivity measurements, and experimental evidence is brought forward to demonstrate the correctness of this supposition. The resistances, moreover, obtained in ohms corresponded very closely with those of solutions prepared with sugar, ferrous sulphate, ammonium sulphate, and sulphuric acid, in the proportions which would result from the reduction of the original amount of ferric alum, the resistance of the sugar being not greatly changed by inversion or partial oxidation.

The results of the experiments indicate that the speed of reduction increases regularly from beginning to end, the cause of this acceleration being accounted for by the production of sulphuric acid during the reaction. The speed of the reduction varies also with the amount of sugar in solution.—J. L. B.

## New Books.

MANUEL D'ANALYSE CHIMIQUE. Appliquée à L'Examen des Produits Industriels et Commerciaux. Par EMIL FLEURENT, DÉS. SC., Professeur remplaçant du Cours de Chimie Industrielle au Conservatoire Nat. des Arts et Métiers. Georges Carre et C. Naud, 3, rue Racine, Paris. 1898. Price 12 frs. H. Grevel and Co., 33, King Street, Covent Garden, W.C.

THIS 8vo volume, bound in cloth, and containing 582 pages of subject-matter, is devoted to the subject of Chemical Analysis applied to technical products. The work is illustrated with 101 beautifully executed engravings, and for index, a carefully classified table of contents is given at the end of the book. The following subjects are treated of:—Introductory Observations.—I. Laboratory Organisation. II. The Reagents: Preparation and Use. III. Taking Samples. IV. Interpretation of the Analytical Results. Part I. Mineral Substances.—Qualitative. I. Bases. II. Acids, &c. Chap. II. Quantitative Analysis of Mineral Substances. Quantitative Analysis of Metallic Products and their Derivatives. Methods of Analysing certain Alloys. Methods of Analysing certain Inorganic Colours. Limes, Mortars, and Cements. Manure Analysis. Part II. Organic Substances. Chap. I.—I. Elementary Organic Analysis. II. Kjeldahl's Method. III. Dumas' Method of Determining Nitrogen. Chap. II.—Study of Soils. III. Complete Analysis of a Manure. IV. Analyses of Vegetable and Animal Products. V. Analytical Study of Fermented Liquors. VI. Analysis of Textiles. VII. Volumetric Determination of Acetone in Denatured Alcohols. VIII. Flash Point of Petroleum, &c.

SUBJECT-MATTER INDEX OF TECHNICAL AND SCIENTIFIC PERIODICALS. Compiled by the Order of the (German) Imperial Patent Office. Year 1896. Carl Heymann's Verlag, Mauerstrasse 44, Berlin. Price M. 18. Williams and Norgate, 14, Henrietta Street, Covent Garden, London, W.C. Gustav E. Stechert, 9, East 16th Street, New York.

This important work, of quarto size, is written in German, English, and French. It commences with an Index of cited periodicals, and of the abbreviations of titles afterwards to be used, which fills eight columns. There are 506 pages of subject-matter, i.e., index matter, and these are followed by a specially detailed alphabetical index of the subjects treated of therein. But the index matter itself is also in a certain sense treated alphabetically. The general or principal subjects are alphabetically arranged, whilst the subsidiary titles or subjects known by authors' or patentees' names, follow in due order under these. When, however, a Chemical Substance (such, e.g., as Acetylene) is indexed, its name appears at the head of its class, and then a special classification follows, with headings suited to a Chemical Substance. Thus: "(1) Properties," and then grouped below, the references to the names of investigators with literary sources appended; "(2) Production or Preparation"; "(3) Applications," and "(4) Explosions and Sundries." Thus, a person desiring information on Acetylene generally (for he might find it under "*Calcium Carbide*" as well as under "*Acetylene*"), may turn it up first in the alphabetical index at the end. If he be specially anxious for information on the narrower issue of "Explosions in the use of Acetylene," he will find all such reference information in sub-group 4, under "*Acetylene*," and with the authors' or investigators' names alphabetically arranged. This example will serve generally.

DIE CHEMISCH-TROCKENE REINIGUNG VON KLEIDUNGSSTÜCKEN, U.S.W., MITTELST BENZIN, TETRACHLORKOHLENSTOFFE, U.S.W. Ein Hilfs- und Lehrbuch für Chemische Waschanstalten und Kleiderfärbereien. Von L. ABEL. Gustav Weigel, Leipzig. Price 1s. 8d. H. Grevel and Co., 33, King Street, Covent Garden, London, W.C.

8vo volume in pamphlet form, containing 58 pages of subject matter illustrated with numerous woodcuts representing apparatus and machinery used in the processes of "Dry-cleaning of Articles of Clothing." The text of the work is subdivided into the following sections:—I. The Sorting and Arrangement of the Goods. II. The Reservoir. III. The Cleansing Agents: Petroleum Benzine, Benzol, Toluol, and Xylol. IV. Carbon Tetrachloride. V. The Washing Machines, with single and double covers. VI. The Wet Cleansing. VII. Cleansing of Glacé, Kid, and Leather Gloves. VIII. Processes for Cleaning and Restoring ordinary Carpets. IX. English Process for ditto.

## Trade Report.

### EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

#### VENEZUELA.

*Bd. of Trade J., Dec. 1897, 704.*

#### *Regulations for the Importation of Butter and other Fats.*

The *Journal Oficial* of the 4th November publishes a notice stating that the Government of Venezuela has recently decreed that the Customs authorities are to disregard all certificates of analysis as to the nature of imported lard or butter which are made by foreign chemists. Importers of the above products must furnish a certificate made out by a Venezuelan chemist, and affixed to the manifest. In places where there is no chemist, a similar certificate must be procured from some competent person appointed by the Customs officials.

The above decree is the result of the importation of various kinds of fat or margarine, subject to a duty of 1·25 francs per kilo., under the name of pure fat and

butter (0.25 per kilo.). It applies especially to fats and butters of American origin, which occupy a preponderating place in the Venezuelan market.

#### PETROLEUM IN THE DUTCH EAST INDIES.

*Bd. of Trade J., Dec. 1897, 726.*

The French Consul at Batavia reports that the production of petroleum in the Dutch East Indies increased from 3,770,200 litres in 1890 to 17,680,100 litres in 1894, to 39,604,600 in 1895, and to 64,104,300 in 1896.

Thus, it is seen the production in 1896 is 18 times as large as in 1890, and since 1894 it may be said that it has almost doubled each year.

Not content with checking the current of foreign importation and with causing Russian and American importations to withdraw in a large measure, the owners of the deposits in the Malay Archipelago, and especially those of Sumatra, have commenced to export to the neighbouring territory. The following figures show the exports in question:—

Year.	Litres.
1890	56,356
1891	65,492
1892	3,912,555
1893	11,037,132
1894	26,587,884
1895	36,330,411

Never before the year 1892 did the foreign sales reach the importance which they attained in that year, with a figure of almost four million litres, and in a period of four years it has increased in a proportion of nine to one. Further information, which the newspapers of Batavia give, is to the effect that new sources, richer still than those of Sumatra, have recently been discovered in Balangan, in the district of Amoenai, on the Island of Borneo.

#### THE WOOD-PULP AND CELLULOSE INDUSTRY OF NORWAY.

*Foreign Office Annual Series, 20, 13.*

In a report to the Foreign Office by Mr. Dundas, H.M. Consul-General at Christiania, it is stated that wood-pulp and cellulose is one of the most important export industries of Norway, and though of comparatively recent development, it has advanced with marvellous rapidity. For Norwegian wood-grinding factories 1896 was about an average year, and for cellulose the demand all through the year was in excess of the supply. The total exportation of this article in 1896 was 314,280 tons (of which 34,803 tons were Swedish production), of the estimated value of \$54,560*l.*, against 276,047 tons (of which 29,822 tons were of Swedish production) and 748,222*l.* in 1895.

The bulk of the production of this article goes to Great Britain, the next most important customers being France, Belgium, Denmark, and Spain.

Some idea of the share taken by Great Britain in this trade may be formed when it is mentioned that during 1896 she imported pulp to the value of 616,210*l.* out of the total estimated value given above. The following ports were the chief centres for the export of wood-pulp and cellulose in 1896:—

Port.	Quantity.
Christiania.....	7,084
Skien.....	20,062
Fredrikshald.....	12,107
Drammen.....	150,243
Arendal.....	2,773
Larvik.....	5,142

The number of factories engaged in the production of wood-pulp at the end of 1896 was 62, and two more were in course of construction.

#### GENERAL TRADE NOTES.

##### THE AMERICAN BEET-SUGAR INDUSTRY.

*Scient. Amer., Nov. 20, 1897, 323.*

This autumn, there will be in operation nine beet-sugar plants whose daily capacities in tons of beets per day of 24 hours each are approximately as follows:—

Watsonville, Cal.....	1,000
Chico, Cal.....	800
Alvarado, Cal.....	400
Los Alamos, Cal.....	300
Eden, Utah.....	100
Grand Island, Neb.....	200
N. A. 60k, Neb.....	300
Eden, N. M.....	200
Reno, N. Y.....	200
Total.....	4,200

Last year the seven of these plants that were then in operation produced about 40,000 tons of sugar. What the output of this season will be can only be estimated roughly at this date, but it ought to be between 45,000 and 50,000 tons.

#### DAINGER OF EXPLOSION AND FIRE IN THE MANUFACTURE AND STORAGE OF ALUMINIUM BRONZE COLOURS.

*Zeits. Oeffentl. Chem.; through Sc. Amer.,*

*Dec. 4, 1897, 18293.*

The author observed repeatedly that aluminium bronze colours oxidized in the settling vessels to aluminium hydrate with evolution of hydrogen. The decomposition by water only took place if the temperature of the rooms in which were the settling vessels rose above 25° C. The evolution of hydrogen begins slowly, but in consequence of the heat of the reaction, becomes very vigorous. As there may be present in a settling vessel 6 kilos. or more of the bronze colour capable of evolving at least 7 cb. m. of hydrogen, there is the possibility of a dangerous explosion by the formation of considerable quantities of inflammable gas in the rooms. By the admission of moisture and heat to packed aluminium bronze, evolution of hydrogen may take place, and if the packing material be inflammable, may lead to fire. Spontaneous combustion of aluminium bronze colours was also caused by friction or blows, due probably to small quantities of fat adhering to the powder. These phenomena were not observed with bronze colours made from copper-zinc or copper-tin alloys.

#### THE PRESENT PRODUCTION OF PETROLEUM.

*Dingler's Polyt. J., 1897, 306, [6], 143; through Oester. Zeits. f. Berg- u. Hüttenw.*

The present production of petroleum is estimated at more than 1,100,000,000 hectolitres, of which the United States furnish 101,000,000; Russia, 73,000,000; Austro-Hungary, 27,000,000; Canada, 1,530,000; India, 570,000; and Java, 560,000 hectolitres; the remainder comes from Peru, Roumania, Germany, Japan, Italy, &c. In the great Appalachian coal fields, which furnish 59,000,000 hectolitres out of the total production of the United States, 20–25 springs were recently opened, two of which yield 270 hectolitres daily; a considerable increase in production has also occurred in South California and Wyoming. The greatest increase of production, however, is anticipated from Peru, where the principal occurrence is situated in the district of Pucallpa and extends over more than 180 square myriameters. Of 49 springs which have been sunk since 1892, 14 have proved profitable, some of them yielding 130–140 hectolitres per day.

In Russia, 269 new springs were opened in 1895, at an average depth of 163 metres; 1,371 springs have been bored during the last six years. Of the year's production of 73,000,000 hectolitres, 23,000,000 hectolitres were obtained by simple running off, and the remainder by means of windlass and buckets.—A. S.

## FRAUDULENT PRACTICE IN OLIVE-OIL TRADE.

*Chem. Zeit.* 1897, 21, 749.

The head of a firm in the olive-oil trade has recently been condemned before the Hamburger Landgericht, and received a very heavy sentence, consisting of imprisonment, loss of civic rights, and a fine, for repeated and extensive frauds. The fraud consisted in having sold for many years as pure, olive oil adulterated with from one third to one-half of cotton-seed oil, and olefin mixed with mineral oil in similar proportion, the former for use in the textile industries, the latter for the treatment of wool. The mixtures were effected in free ports and passed through the Customs office as pure olive oil (or olein respectively), which, when denatured, is exempt from duty. During the tariff war with Spain, Spanish oil was imported as Italian, in order to escape the extra duty. In order to persuade inland purchasers to the belief that it was practically pure olive oil, and to account for its low price, the said firm had also a house in Trieste, through which the purchases were made.—W. G. M.

## QUICKSILVER PRODUCTION IN THE UNITED STATES.

*Eng. and Mining J.*, Nov. 20, 1897, 601.

The quicksilver receipts at San Francisco this year have unusually light; for the ten months ending October 31st they were 14,372 flasks (of 76 lb. each), against 22,709 flasks for the corresponding time last year. This does not imply a corresponding fall in production, however, since it is understood that shipments direct from the mines, not consigned to or through San Francisco, have been larger this year than in 1896. It is well known, however, that there is a falling off in the production of quicksilver this year, as we pointed out previously in giving the statistics of the first six months. The Sulphur Banks Mine in Lake County has closed down, it is said permanently, and the Altoona Mine in Trinity County has been idle on account of the flooding of the workings. An attempt to unwater toom is now being made, but considerable doubt is expressed as to the success of this.

Outside of California there has been no quicksilver production in the United States this year. The Oregon discoveries, which were reported some time ago, have not been developed, and nothing has been heard from the supposed deposits in Texas. Nor have the new mines in British Columbia proved yet to be of any special consequence. In Mexico, however, there have been some new discoveries of quicksilver, which appear to be of much importance, and we are likely to see a large increase in the production of that country on account of them. In view of the large amount of quicksilver which is used in the metallurgical practice in Mexico, proportionately much more than in the United States, it is a matter of a good deal of interest to the citizens of that republic to obtain the necessary supply from domestic sources; heretofore, notwithstanding the exploitation of three important mines, it has been necessary to import quicksilver from the United States.

The demand for quicksilver in the United States is good, and the price at present is higher than it has been for nearly two years past.

## CALCINING ORES BEFORE TREATMENT WITH CYANIDE.

*Eng. and Mining J.*, April 12, 1897, 669.

Hitherto, all the ores of the Mercur district in Utah, where the cyanide treatment had the first marked success in the United States, were leached raw. For a considerable period it has been known that in many instances a portion of the gold was lost, but owners were apparently satisfied, so long as operations paid a profit. The model De La Mar plant, now being built, is arranged to calcine all ore and roast the arsenical products. Experiments recently made on clayey La Cigale ore, on the West Dip portion of Mercur camp, show that, by calcining, the ore leaches better in 24 hours than in five days without calcining; and calcining furnaces are to be immediately put in. Like results were had on Sacramento, Sun-shine, and other ores. Even the Mercur management now admits that this innovation can be adopted to advantage, though the ores of this mine are

more cherty and freer from slimy material than any of their neighbours. In all likelihood, within a year, every cyanide mill of that camp will be equipped with calcining furnaces. By this means also, it is believed that most of the mill tailing dumps can be made to afford a profit, and they will probably be some day reworked. (See also this Journal, 1897, 803.)

## ENGLISH COAL AND ITS COMPETITION WITH FOREIGN COAL.

*Archiv. für Post und Telegraphie*, 1897, 414; *Proc. Inst. Civil Eng.* 1897, 130, [4], 54.

It is stated that anxiety is being caused in German commercial circles, owing to the fact that the export of coke and coal from England to Germany is increasing more rapidly than the gross English exports of these materials. The gross export in 1895 was 33,112,000 tons, an increase of 38,000 tons over that of 1894, whilst the export to Germany in 1895 was 4,141,000 tons, an increase of 25,000 tons over that of 1894. For the nine months, January to October 1896, the increase in the gross export was only 4 per cent., whilst the increase in the export to Germany during that period was 14 per cent.

The annual consumption of coal and coke per head of population in Great Britain increased 660 lb. between the years 1875 and 1895; the corresponding increase in Germany amounted to 1,980 lb. The production of coal the colonies and foreign possessions of Great Britain is increasing, the total in 1894 amounting to 11,368,000 tons. India produced only 1,320,000 tons in 1883, but in 1895 a total of 4,396,000 tons; the small output of coal in South Africa is also increasing.

It is pointed out that Japan is becoming a serious competitor for the coal trade of East Asia, her output already amounting to 1,400,000 tons. It is stated that the Germans have begun to work the coal fields in Amoy, and the Chinese the Nankin fields. The bulk of the Russian output of 8,667,000 tons, is produced by the Don fields.

England supplies almost all the coal used in Italy, 50 per cent. of that used in Spain, and 11—12 per cent. of that used in France; but English coal cannot now be delivered and sold at a profit in the Black Sea. The Scandinavian peninsula obtains 90 per cent. of its coal from Great Britain. Coal can be delivered to the German coast more cheaply from Great Britain than from the German coal fields, and the output of the German pits does not keep pace with the home demand. The author considers that the only way of enabling Germany to compete with England in the coal trade is to lower German freights.

—A. S.

## BOARD OF TRADE RETURNS.

## SUMMARY OF IMPORTS.

Alizarin..... Value £	..	..	24,965	26,688
Indigo and other ..	..	..	46,744	48,826
Indigo..... Cwt.	..	712	10,661	13,116
Nitrate of potash ..	18,780	16,547	15,541	8,787
Valonia..... Tons	762	1,528	8,925	15,139
Other articles... Value £	..	..	96,456	74,777
Total value of chemicals	..	..	374,377	372,699

## IMPORTS OF OILS FOR MONTH ENDING 30TH NOVEMBER.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Cocoa-nut..... Cwt.	27,816	8,887	32,623	12,757
Olive..... Tons	919	583	31,151	20,831
Palm..... Cwt.	86,183	76,812	100,556	80,526
Petroleum..... Gall.	18,914,067	16,680,091	381,767	283,434
Seed..... Tons	3,657	3,190	77,810	66,764
Train, &c., .. Tons	2,167	1,220	39,230	19,434
Turpentine..... Cwt.	41,823	56,816	40,428	63,457
Other articles .. Value £	..	..	104,193	97,877
Total value of oils...	..	..	867,822	645,080

EXPORTS OF METALS (OTHER THAN MACHINERY) FOR  
MONTH ENDING 30TH NOVEMBER.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Brass..... Cwt.	10,769	10,454	44,859	62,864
Copper:—			£	£
Unwrought.....	25,396	42,069	644,655	197,844
Wrought.....	22,262	26,525	70,092	82,812
Mixed metal.....	21,021	22,277	19,505	52,425
Hardware..... Value £	..	..	178,929	181,190
Implement.....	..	..	116,084	128,533
Iron and steel... Tons	29,462	34,426	127,706	219,513
Lead.....	2,549	2,427	33,481	35,449
Plated wares... Value £	..	..	43,177	49,725
Telegraph wires ..	..	..	48,671	34,341
Pin..... Cwt.	12,453	8,767	39,018	28,010
Zinc.....	12,150	16,717	9,262	12,551
Other articles .. Value £	..	..	65,138	193,295
Total value .....	..	..	2,729,569	3,026,532

IMPORTS OF RAW MATERIAL FOR NON-TEXTILE  
INDUSTRIES FOR MONTH ENDING 30TH NOVEMBER.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Bark, Peruvian .. Cwt.	3,568	1,115	6,361	2,652
Bristles..... Lb.	398,951	322,369	19,784	38,166
Caoutchouc..... Cwt.	37,421	34,341	95,490	355,447
Gum:—				
Arabic.....	4,392	3,695	11,453	8,587
Lac, &c., ..	10,467	11,267	52,565	35,796
Gutta-percha.....	3,162	1,780	52,330	15,288
Hides, raw:—				
Dry.....	27,399	44,495	62,749	116,875
Wet.....	77,636	60,060	165,966	124,613
Ivory.....	825	708	33,723	32,565
Manure:—				
Gaano..... Tons	687	2,468	2,065	14,120
Bones.....	2,722	3,478	9,122	12,268
Nitrate of soda... ..	8,106	4,460	64,157	32,852
Phosphate of lime ..	16,126	20,749	24,620	32,368
Paraffin..... Cwt.	77,104	83,340	76,481	72,122
Linen rags..... Tons	1,565	2,176	16,637	26,849
Esparto.....	13,364	12,720	51,134	54,775
Pulp of wood.....	25,851	39,403	145,183	164,266
Rosin..... Cwt.	150,605	69,632	40,897	13,688
Tallow and stearin ..	147,976	153,330	153,419	152,737
Tar..... Barrels	10,219	15,088	8,974	11,192
Wood:—				
Hewn..... Loads	155,049	204,762	308,494	433,657
Sawn.....	502,982	555,464	1,084,776	1,285,431
Staves.....	10,222	38,463	39,660	..
Mahogany..... Tons	3,860	7,050	35,489	64,163
Other articles... Value £	..	..	945,808	914,511
Total value .....	..	..	3,914,085	4,973,889

EXPORTS OF MISCELLANEOUS ARTICLES FOR MONTH  
ENDING 30TH NOVEMBER.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Gumpowder..... Lb.	543,800	339,600	12,442	8,291
Military stores... Value £	..	..	92,225	136,897
Candles..... Lb.	1,921,000	2,415,000	27,781	34,420
Caoutchouc..... Value £	..	..	105,237	128,551
Gun cotton..... Tons	24,845	26,325	40,426	43,638
Products of coal Value £	..	..	109,440	145,192
Hardware.....	..	..	13,451	15,461
Stoneware.....	..	..	13,448	15,201
Glasses:—				
Plate..... Sq. Ft.	119,628	126,111	6,724	7,288
Flint..... Cwt.	7,218	8,475	18,694	20,489
Buttons.....	64,769	74,419	20,384	33,845
Other kinds.....	29,514	29,618	16,000	19,866
Leather:—				
Unwrought .. Value £	11,952	13,325	194,758	104,887
Wrought..... Value £	..	..	34,279	36,765
Seed oil..... Tons	5,424	8,826	37,657	58,825
Flourcloth..... Sq. Yds.	1,118,000	1,206,700	29,840	81,961
Painters' materials Val. £	..	..	126,434	142,141
Paper..... Cwt.	81,965	75,341	127,078	117,827
Ropes..... Tons	32,845	46,421	12,224	24,451
Soap..... Cwt.	9,228	61,351	45,262	64,200
Total value .....	..	..	2,682,539	2,848,311

Besides the above, drugs to the value of 98,620*l.* were imported, as against 85,821*l.* in November 1896.

EXPORTS OF DRUGS AND CHEMICALS FOR MONTH  
ENDING 30TH NOVEMBER.

Articles.	Quantities.		Values.	
	1896.	1897.	1896.	1897.
Alkali..... Cwt.	414,789	472,170	107,161	121,837
Bleaching materials ..	111,174	131,368	37,428	41,116
Chemical manures .. Tons	17,857	25,305	101,406	150,898
Medicines..... Value £	..	..	85,379	102,821
Other articles.... "	..	..	200,024	337,065
Total value .....	..	..	501,908	753,840

## Monthly Patent List.

\* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

## I.—PLANT, APPARATUS, AND MACHINERY.

## APPLICATIONS.

26,635. J. Weck. Improvement in sterilising apparatus. Nov. 15.

26,664. F. W. Lord. Improvements in apparatus for cooling and drying air to be used in storage chambers containing perishable produce. Complete Specification. Nov. 15.

27,061. J. E. Thornton and J. P. Lea. Improvements in generators, and apparatus in connection therewith. Nov. 19.

27,374. C. E. Müller and R. F. Hurran. A new or improved flask for bacteriological cultivations. Nov. 22.

27,458. J. McLaren and H. McLaren. Apparatus for separating oil and water or other liquids of different specific gravities. Nov. 23.

27,711. J. H. Carpenter. Improved apparatus for purifying air and gases, also for heating and cooling of the same. Nov. 25.

28,006. G. C. Foncher. — From C. A. Garrioli fils, France. Improvements in vaporising or atomising apparatus. Nov. 27.

28,113. J. Bock. Process and apparatus for obtaining large, well-formed crystals from solution. Nov. 29.

28,368. J. Leich and S. Delporte. An improved apparatus for compressing and mixing gas and air, more particularly for lighting purposes; also applicable for air compressing. Complete Specification. Dec. 1.

28,747. J. McNeil and J. Lewkowsitch. Improvements in evaporating or concentrating apparatus. Dec. 6.

28,998. H. H. Lake. — From The Manhattan Concentrator Company, United States. Improvements in machines for separating substances of different specific gravities. Dec. 7.

29,178. J. G. Lorrain. — From C. S. Rueck-stahl, United States. A new or improved thermometer. Dec. 9.

29,286. T. H. P. Heriot. Apparatus for separating suspended solids from liquids, for separating soluble from insoluble solid matters, and for partially separating insoluble solid matters of different specific gravities. Dec. 10.

29,326. J. Godfrey and H. J. Hayes. Improvements in the construction of mechanical calcining furnaces. Dec. 11.

## COMPLETE SPECIFICATIONS ACCEPTED.\*

1896.

29,757. R. H. Yeomans. Furnaces for evaporating pans and other purposes. Dec. 15.

29,884. T. G. Webb. Improvements in and connected with apparatus for concentrating sulphuric acid and other liquids. Dec. 8.

1897.

5588. W. L. Wise. — From F. J. Brischar. Closing device for bottles and the like designed to contain gas or other fluid under high pressure. Nov. 24.

5589. W. L. Wise. — From F. J. Brischar. Closing device for bottles and the like, designed to contain gas or other fluid under high pressure. Nov. 24.

18,816. L. Fremy. Apparatus for sterilising liquids and for use as a receptacle for containing the same. Nov. 24.

21,989. W. D. Cliff and the Leeds Fireclay Company, Ltd. Improvements in inclined retorts. Nov. 24.

24,698. M. Deville. Centrifugal apparatus for sorting or separating ores. Dec. 15.

## II.—FUEL, GAS, AND LIGHT.

## APPLICATIONS.

23,887A. B. J. Atterbury. Improvements in apparatus for the production of acetylene gas. Nov. 20. Date claimed under Patents Rule 19, Oct. 16, 1897.

26,566. J. Gore. Improved burner for acetylene and like gases. Nov. 15.

26,567. F. G. Bartlett. An improvement relating to incandescent gas-lighting burners. Nov. 15.

26,588. W. S. Sargeant. Improved method of employing liquid fuel. Nov. 15.

26,591. A. Wartenweiler. New or improved acetylene gas lantern. Nov. 15.

26,594. E. Helvig. A new apparatus for producing acetylene gas. Nov. 15.

26,633. G. W. Chalmers. Improvements in or connected with incandescent gas burners wherein fragile mantles are used. Nov. 15.

26,745. G. Brogden. Improvements in incandescent mantle supports. Nov. 16.

26,776. J. Kremer. Improvements in acetylene gas generators. Nov. 16.

26,842. E. S. Bond. Improvements in means for selectively using acetylene or the like gas with ordinary lamp apparatus. Nov. 17.

26,843. E. S. Bond. Improvements in means for storing and using calcium carbide or the like for acetylene and the like gas-generating apparatus. Nov. 17.

27,016. A. C. Fraser. Improvements in methods of and apparatus for burning acetylene and other rich gases. Nov. 18. Date applied for April 19, 1897, being date of Application in United States.

27,029. R. von Maiti. Improvements in acetylene lamps. Nov. 18.

27,065. J. Benjamin. An improved gasometer for generating acetylene gas. Nov. 19.

27,240. A. Forcher. Improved acetylene gas generator for illuminating railway carriages. Complete Specification. Nov. 20.

27,288. J. Reibel. Improvements in apparatus for generating acetylene gas. Nov. 20. Date applied for May 14, 1897, being date of application in France.

27,300. J. Reibel. Improvements in devices for feeding the carburet in acetylene gas generating apparatus. Nov. 20.

27,317. S. McNamee. Improvements in preparing peat for sanitary fuel and other purposes. Nov. 22.

27,360. J. Hopwood and C. Cummins. An improved fuel. Nov. 22.

27,379. B. Talbot and W. B. Hughes. Certain improvements in the construction of gas producers. Complete Specification. Nov. 22.

27,405. R. Farrington, M. H. Hawes, and W. H. Hand. Improvements in or relating to incandescent lighting. Nov. 22.

27,416. A. A. Dickson. Improved process and apparatus for forming cold peat into blocks for fuel. Nov. 23.

- 27,128. H. S. Biant. Improvements in and connected with electric furnaces for the production of calcium carbide and other substances. Nov. 23.
- 27,178. R. Fleming and F. Smith. Improved means for mixing air and gas for heating and lighting purposes. Nov. 23.
- 27,536. O. Falbe and E. Borchardt. Improvements in or relating to burners for acetylene gas. Nov. 23.
- 27,593. J. Jameson. Improvements in the production of light and radiant heat by combustion of gas or inflammable vapour. Nov. 24.
- 27,639. W. J. H. Lazarus. Improvements in and connected with the production of acetylene gas. Nov. 24.
- 27,650. A. J. Boulton.—From E. J. Armand-Machin, France. Improvements in or relating to the construction of acetylene gas generators. Nov. 24.
- 27,652. M. Bernstein, Proprietor of the Firm of J. F. Wallmann and Co. Process for the manufacture of automatic igniters for illuminating gas. Complete Specification. Nov. 24.
- 27,703. G. Fincken and J. Rollins. An improved saturating appliance for lime-lighting. Nov. 25.
- 27,767. J. H. Schülke. Improved acetylene gas generator. Complete Specification. Nov. 25.
- 27,869. J. Bowing. Improvements in the manufacture of coke, and in apparatus therefor. Nov. 26.
- 27,876. The Liver Acetylene Gas Company, Ltd., and E. Evans. Improvements in apparatus for generating acetylene or other gas generated by the addition of a liquid to a solid. Nov. 26.
- 27,886. J. Skar. Process for the manufacture of fuel blocks. Nov. 26. Date applied for, May 4, 1897, being date of application in Norway. Complete Specification.
- 28,001. H. Winekler.—From H. Freudenthal, Germany. Improved means and ingredients for effecting an increase in the lighting properties of gas and oil flames. Nov. 27.
- 28,003. J. S. Billwiller. Method of and means or apparatus for purifying the products of combustion of acetylene gas flames. Nov. 27.
- 28,012. H. H. Lake.—From W. A. Shearer, South African Republic. Improved apparatus for the production of acetylene gas from calcium carbide. Nov. 27.
- 28,031. E. A. Wood. Improvements relating to incandescent gas-burners. Nov. 29.
- 28,094. W. Tyree. An improved acetylene gas generator. Complete Specification. Nov. 29.
- 28,102. M. Wagner. Improvements in apparatus for generating acetylene gas. Complete Specification. Nov. 29.
- 28,106. A. J. Evans. An improved gas producer. Nov. 29.
- 28,226. H. L. Hartenstein. See Class VII.
- 28,258. L. J. Keek. Improved lamp for generating and burning acetylene gas. Nov. 30.
- 28,264. Sir H. Grubb, Kt. Improvements in apparatus for the generation of acetylene gas. Nov. 30.
- 28,368. J. Leich and S. Delporte. See Class I.
- 28,399. E. G. Gearing. Improvements in or relating to acetylene generating and storing apparatus. Dec. 1.
- 28,439. V. Sockeel, A. Lamb, C. H. Drisse, and Suck. Novel apparatus for the production of acetylene gas, also called "Lumière Soleil." Dec. 2.
- 28,448. G. Tripel. A new or improved apparatus for use in burning liquid fuel. Dec. 2.
- 28,477. T. H. Gittins and J. Marshall. Improvements in the manufacture of fuel. Dec. 2.
- 28,496. H. Gardner. Improvements in the manufacture of artificial fuel and fire lighters. Dec. 2.
- 28,504. W. E. Koehs. Improvements in coke ovens and in machinery in connection therewith. Complete Specification. Dec. 3.
- 28,526. J. B. Wigham. A method of increasing the illuminating power of gas made from coal or other material. Dec. 3.
- 28,698. R. Kirk. Improvements in and relating to lamps for generating and using acetylene gas. Dec. 4.
- 28,706. J. Moeller. An improvement in incandescence mantles. Dec. 4.
- 28,778. J. B. Melhuish, M. Guthrie, and J. H. Hughes. A new gas. Complete Specification. Dec. 6.
- 28,798. B. Richard. Improvements in and relating to apparatus for generating and purifying acetylene. Complete Specification. Dec. 6.
- 28,824. H. Bryant. Improvements in apparatus for making illuminating gas. Dec. 6.
- 28,836. J. B. Melhuish. An apparatus for the generation of ethine gas from a carbide of a metal of the alkaline earths. Dec. 7.
- 28,909. G. A. Bröder. Improvements in machinery for discharging gas retorts. Complete Specification. Dec. 7.
- 29,054. J. O. O'Brien.—From E. M. Boule, France. Improvements in apparatus for generating acetylene gas. Complete Specification. Dec. 8.
- 29,096. J. A. Drake and J. S. Marsland. Improvements relating to inclined gas retorts. Dec. 9.
- 29,103. R. Farrington. Improvements in and relating to a preparation for cleaning and strengthening incandescent mantles. Dec. 9.
- 29,114. C. J. Shears. A process for treating incandescent mantles for illuminating purposes. Dec. 9.
- 29,201. E. V. Prevost, O. Raus, and A. Cerkel. Improvements in apparatus for the production of acetylene. Dec. 9.
- 29,234. W. H. Russell and G. E. Russell. Improvements in and relating to the manufacture of gas. Complete Specification. Dec. 10.
- 29,277. E. Evans. Improvements in holding or storing carbide of calcium and other like chemical, and in regulating the evolution of acetylene or other gas therefrom. Dec. 10.
- 29,304. M. H. Hawes, R. Farrington, and W. H. Hand. Improvements in or relating to gas and oil lighting. Dec. 10.
- 29,393. A. M. G. Sabillot. Apparatus for generating acetylene gas. Dec. 11.
- 29,405. V. Maréchal and A. Morvan. Improvements relating to acetylene generators. Complete Specification. Filed Dec. 11. Date applied for June 11, 1897, being date of application in France.
- 29,421. D. Kempe. Improvements in apparatus for burning vaporised petroleum and the like for heating and illuminating purposes. Complete Specification. Dec. 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

19,741. J. Steiger. Manufacture of artificial fuel. Dec. 15.

27,194. A. J. de Pimental Hargreaves. Manufacture of acetylene gas, and apparatus therefor. Dec. 8.

27,744. A. Kiesewalter. Manufacture of a carbide which, by its decomposition by water, produces acetylene gas. Dec. 15.

28,265. E. Barker. The incandescent fire ball. Dec. 8.

28,588. L. Mond. Production of a mixture of air and water-vapour for gas producers. Dec. 1.

28,721. R. G. Leventhorpe. Production of hydrogen gas, and apparatus therefor. Dec. 15.

1897.

658. L. Tédé. Apparatus for the production of acetylene. Nov. 24.

1254. R. J. Moss. Apparatus for generating and purifying acetylene gas. Nov. 24.

1370. F. G. Bartlett. Improvements relating to incandescent gas lighting. Dec. 8.

1784. W. P. Thompson.—From A. Gobron. Portable apparatus for generating and burning acetylene gas. Nov. 24.

1929. T. Thorp and T. G. Marsh. Apparatus for the production of acetylene from calcium carbide. Dec. 1.

1952. J. C. Mewburn.—From A. M. Scott. Apparatus for generating gas by the reaction of solid substances with water or other liquid, especially applicable to the generation of acetylene gas by contact of water with metallic carbides. Dec. 1.

2129. W. L. Wise.—From A. Piatti and Co. Manufacture of gas. Nov. 24.

6132. W. Clinie and A. Watson, jun. Gas producers. Nov. 24.

9294. A. H. Barthez. Improved portable and automatic apparatus for the production of acetylene gas for lighting purposes. Dec. 1.

15,813. E. Andreoli. Manufacture or production of ozone, and apparatus therefor. Dec. 1.

16,890. R. H. Whiteley and W. Ellis. Apparatus for enriching coal gas. Dec. 8.

20,574. G. Lebrun and F. Cornaille. A burner for acetylene and other gases rich in carbon. Nov. 24.

22,625. W. L. Voelker. Manufacturing incandescent materials. Dec. 8.

22,626. W. L. Voelker. Improvements in incandescent materials and mantles, and the process of making same. Dec. 8.

23,802. L. S. Buttington. Acetylene gas generators. Nov. 24.

24,602. G. Mahnke and C. Kraft. Improved means of protection of incandescent gaslight mantles. Dec. 1.

24,815. H. Ottenbruch. Mantles for incandescence gas lighting. Dec. 1.

24,822. A. Syssoyeff and L. Braly. Improvements in auto-luminous compositions. Dec. 8.

25,632. R. E. Perraga. Method and apparatus for generating formaldehyde gas. Dec. 8.

26,311. J. Janz. Manufacture of fabrics for incandescence mantles for illuminating purposes. Dec. 15.

26,325. A. J. Boulton.—From F. Alexandre, France. Apparatus for the manufacture and use of acetylene gas. Dec. 15.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

#### APPLICATIONS.

28,553. A. Gordon. Improvements in and relating to retorts for the distillation of shale and other substances. Dec. 4.

#### COMPLETE SPECIFICATION ACCEPTED.

1897.

2515. H. J. Dawes.—Distillation and breaking up of liquid hydrocarbons and similar substances. Dec. 1.

### IV.—COLOURING MATTERS AND DYES.

#### APPLICATIONS.

26,563. W. H. Claus, A. Rée, and L. Marchlewski. Production of new azo colouring matters. Nov. 15.

26,675. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Improvements in the manufacture of derivatives of the naphthalene series. Nov. 15.

27,051. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Manufacture of new colouring matters. Nov. 18.

28,107. S. Pitt.—From L. Cassella and Co., Germany. Improvements in the manufacture of azo dyestuffs and in the production of fast dyeings on animal fibre. Nov. 29.

28,604. H. H. Lake.—From Farbwerk Mülheim vorm. A. Leonhardt and Co., Germany. Improvements in the manufacture of colouring matters. Dec. 3.

28,707. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Manufacture of *m*-oxybenzaldehyde *o*-sulphonic acid. Dec. 4.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1897.

1592. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Manufacture of rhodamine dialkylamides. Nov. 24.

1962. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of blue mordant-dyeing colouring matters. Dec. 8.

2655. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of colouring matters of the rhodamine series. Dec. 8.

2874. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture and production of new disazo dyes on cotton. Dec. 8.

3452. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co. Production of colouring matters. Dec. 8.

4703. W. G. Heyes.—From The Chemical Works, Sandoz. Production of substantive disazo colouring matters. Dec. 15.

22,677. A. Ashworth and J. Bürger. Production of colouring matters. Nov. 24.

23,816. A. Ashworth and J. Bürger. Production of colouring matters. Nov. 24.

### V.—TEXTILES: COTTON, WOOL, SILK, ETC.

#### APPLICATIONS.

27,020. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. A new process for mercerising vegetable fibre. Nov. 18.

27,651. K. Klietsch. Improvements in or relating to the manufacture of linoleum, kamptulicon, and similar materials. Complete Specification. Nov. 24.

27,943. J. Archer and J. Arthur, jun. Improvements in or relating to the manufacture of linoleum and like floor coverings. Nov. 27.

28,380. H. B. Edwards.—From O. M. Thowless, United States. A method of or process for manufacturing raw silk. Dec. 1.

28,491. C. Wetherwax. Improvements in the treatment of vegetable fibres. Dec. 2.

28,631. H. Pauly. An improved process for the manufacture of artificial silk. Dec. 4.

29,072. J. Y. Johnson.—From W. H. Drury, United States. Improvements in the manufacture of yarns, and apparatus therefor. Dec. 8.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

27,483. H. C. Longsdon. Improved yarn-drying apparatus. Nov. 24.

1897.

90. H. W. Godfrey. Manufacture of floorcloth and the like. Nov. 24.

3222. J. Millar. Improvements in textile fabrics or cloths. Dec. 15.

5350. M. Beck. Apparatus for finishing, stretching, mordanting, and drying textile fabrics. Dec. 8.

# VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

## APPLICATIONS.

26,667. P. A. Newton.—From The Alexander Smith and Sons Carpet Company, United States. Improvements in methods of and apparatus for printing or colouring yarn and similar material. Nov. 15.

27,270. C. Delescluse. Improvements in bleaching cotton, linen, and other vegetable textile materials. Nov. 20.

27,690. W. Beaumont. Improvements in apparatus for dyeing, bleaching, and otherwise treating cops of yarn. Complete Specification. Nov. 25.

27,855. E. Fletcher. Improvements in hank-dyeing machines. Nov. 26.

27,937. T. Ingham. An improvement in dyeing. Nov. 27.

28,090. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. A new process for producing black shades on cotton. Nov. 29.

28,115. C. Spindler and C. Göhring. Improvements in the treatment of silk for dyeing and bleaching. Complete Specification. Nov. 29.

29,317. H. Laug, C. Rütter, and M. Rütter. An improved process of dyeing. Dec. 11.

29,359. J. Birtwistle. Improvements in and relating to the dyeing and like treatment of cops and similarly wound yarns. Dec. 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

29,645. W. Hadfield, J. J. Sumner, and H. Hadfield. Apparatus for use in the continuous bleaching and washing of woven goods in the piece, applicable also in the washing and clearing of printed or dyed goods. Dec. 1.

1897.

1629. T. Ingham. Improved dyeing process. Nov. 24.

2620. W. Watson and E. Bentz. Production of coloured discharge patterns on indigo-dyed cotton fabrics in calico printing. Dec. 8.

# VII.—ACIDS, ALKALIS, AND SALTS.

## APPLICATIONS.

27,019. L. H. Frentz. Manufacture of conglomerates containing alkaline oxidising bodies for bleaching linen and other objects. Nov. 18.

27,221. A. R. Scott. Improvements in obtaining chlorine. Nov. 20.

28,226. H. L. Hartenstein. An improved process and apparatus for carburetting calcium. Complete Specification. Nov. 30.

28,688. W. H. Graham. Metallic carbides, and processes and apparatus for their manufacture; applicable also to other purposes. Dec. 4.

29,008. J. Bastick and W. A. Thornton. Improvements in or relating to the manufacture of calcium carbide. Dec. 8.

29,009. J. Bastick and W. A. Thornton. Improvements in or relating to electric furnaces for the production of calcium carbide and other substances. Dec. 8.

29,384. F. J. Bergmann. Process for the production of calcium carbide in blast furnaces. Dec. 11.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

28,294. E. A. Goddin and R. Lees. Process and apparatus for obtaining common salt and other like salts from their solutions. Dec. 8.

29,066. E. J. Hunt and E. F. Watson. Manufacture of chlorine. Dec. 8.

29,884. T. G. Webb. See Class I.

1897.

1248. H. H. Lake.—From J. S. Levy and Co. Process for obtaining barium carbonate from native sulphate of barium. Nov. 24.

1762. G. D. Howard. From H. Howard. Methods of and apparatus for concentrating sulphuric acid or the like. Dec. 8.

1227. F. Ryan, jun., A. Dyson, and The United Alkali Co., Ltd. Manufacture of caustic soda or caustic potash from carbonate of soda or carbonate of potash. Nov. 24.

4747. A. Kuop. Manufacture of nitrates. Dec. 15.

19,512. J. W. Keneval, C. A. Spofford, and J. H. Mead. Means for manufacturing carbides. Dec. 1.

21,073. J. Reich. Method of transforming silicon fluorides and boron fluorides into corresponding fluorides or fluorine compounds. Dec. 1.

22,136. F. Lutze. Process for the preparation of carbonic acid. Dec. 15.

24,524. A. MacNab.—From W. A. Willock, India. Manufacture of bay salt. Dec. 8.

# VIII.—GLASS, POTTERY, AND ENAMELS.

## APPLICATIONS.

26,571. W. Lindsay and D. Anderson. Improvements in and relating to apparatus for the manufacture of glass articles, and appliances for shaping and forming same. Nov. 15.

26,901. A. Houghton. Improvements in the process of and apparatus for drawing glass tubing. Complete Specification. Nov. 17.

27,248. W. Haley. A new power press for pressing glass or metals while in a liquid state. Nov. 20.

27,786. T. Pfister. Improvements in cloisonné and mosaic work. Nov. 26.

27,796. J. H. Lea. Improved kilns and ovens for use in firing tiles and other pottery-ware. Nov. 26.

27,841. W. Owen. Improvements in kilns for calcining or fritting materials used in the production of potters' glazes. Nov. 26.

28,120. J. T. Newell. Improvements in or relating to furnaces for glass or ceramic ware. Nov. 29.

28,345. L. Grote. Improved method of and apparatus for manufacturing water-glass. Dec. 1.

28,466. C. Keller and A. Keller. Manufacture of ceramic, earthenware, porcelain, stoneware, glass, crystal, and such like ware, with metallic decorations, and furnaces or ovens therefor. Dec. 2.

28,885. C. Kempton, sen. An improved furnace for making glass and manipulating glassware. Dec. 7.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

28,789. C. F. Ravenhill. Glaze for clay tobacco pipes. Dec. 8.

1897.

1871. A. E. Doucde. Method and means for connecting tubes and pipes of stoneware, earthenware, and glass. Dec. 1.

24,317. B. Swindon. Method of and composition for polishing glass. Dec. 1.

# IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

## APPLICATIONS.

27,104. H. Kiehler. New or improved material for flooring. Complete Specification. Nov. 19.

27,561. W. Johnson and H. Walker. Improvements in or relating to kilns for burning cements, limes, and other like substances. Nov. 24.

27,077. A. E. Scharffetter.—From C. Franz, Austria-Hungary. Improvements in the manufacture of bricks for building purposes. Nov. 25.

27,682. W. P. Lugham. Improvements in or connected with fireproof walls or partitions. Nov. 25.

27,825. J. C. Sellars. Improvements in the manufacture of cement. Complete Specification. Nov. 26.

27,939. F. M. Lyte, O. J. Steinhart, and W. H. Wickham. Improvements in the preparation of unflammable wood. Nov. 27.

28,276. H. Spatz and H. Quistorp. Process for the production of asphalt powder for making street asphaltic plaster. Nov. 30.

28,310. P. Tickle. Through-burning of clay and terra cotta goods. Dec. 1.

28,656. W. H. Northcutt. Combination paving blocks and system of paving. Complete Specification. Dec. 4.

28,842. H. W. Gruner. Improved composition for the manufacture of artificial stone, cement, and the like. Dec. 7.

28,938. H. V. Simpson. Improvements in treating wood for the purpose of rendering it non-inflammable or for preserving it. Dec. 7.

28,974. T. Potter. Improvements in fireproof floors, ceilings, and partitions. Dec. 8.

29,020. F. S. Smith. Improvements in the construction of bricks and other moulded building materials. Dec. 8.

29,137. A. R. Crawford and W. Crawford. Improvements in the manufacture of briquettes for heating purposes. Dec. 9.

29,219. The British Marble and Slate Syndicate, Ltd., and W. F. Baker. Improved method and means for utilising slate refuse. Dec. 10.

29,263. C. Hannay. Improvements in firebricks, slabs, or tiles. Dec. 10.

29,420. E. Vleck. An improved method of manufacturing plates, slabs, or the like for building purposes. Complete Specification. Dec. 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

26,792. H. Brockhuys. Manufacturing a material for covering walls and floors. Dec. 1.

29,109. W. H. Coward. Manufacture of composition and other compressed blocks for paving. Nov. 24.

29,212. Petrifite, Ltd.—From J. Steiger. Manufacture of cement. Nov. 24.

1897.

1881. La Société Metallurgique de Champigneulle et Neuves-Maisons. Manufacture of cement. Dec. 15.

#### X.—METALLURGY, MINING, Etc.

##### APPLICATIONS.

26,706. H. R. Angel. Improvements in the reduction of ores containing antimony. Nov. 16.

26,891. J. C. Richardson. Improvements in or relating to methods (wet) of treating gold, silver, and other ores. Nov. 17.

27,915. J. E. Dowson. An improved process relating to the reduction of ores, and improvements in furnaces therefor. Nov. 18.

27,981. W. B. Johnson.—From The Carnegie Steel Company, Ltd., United States. Improvements in apparatus or appliances for casting metals. Nov. 19.

27,160. B. H. Thwaite and H. V. Holden. Improvements in decarburising cast iron or steel, and apparatus for that purpose. Nov. 19.

27,248. W. Haley. See Class VIII.

27,546. T. Levoz. New construction of converter apparatus for producing steel and wrought iron of superior quality. Complete Specification. Nov. 23.

27,550. C. P. Shrewshury. Improvements in and connected with the extraction of gold. Nov. 23.

27,555. G. D. Burton. A new or improved process of and apparatus for treating ores. Nov. 23.

27,614. J. W. Clarke. Improvements in apparatus for concentrating and amalgamating ores. Nov. 24.

27,702. J. Parry and G. H. Llewellyn. Improvements in the manufacture of crude metal suitable for the more rapid production of steel by the Siemens or open-hearth process. Nov. 25.

27,717. W. Buckley. Improvements in or applicable to ingot and similar moulds, and to the manufacture of ingots. Complete Specification. Nov. 25.

27,752. R. A. Hadfield. Improved manufacture of steel. Nov. 25.

27,753. R. A. Hadfield. Improved manufacture of steel. Nov. 25.

27,881. F. D. James and M. B. Fox. An improved metal, and method of producing it. Nov. 26.

28,440. E. Govett. Machine and apparatus for the extraction of gold, silver, and other metals from their ores by amalgamation with lead. Dec. 2.

28,441. H. C. Jenkins. The treatment of refractory gold ores. Dec. 2.

28,568. C. M. White.—From King, United States. A new or improved process of annealing iron castings. Complete Specification. Dec. 3.

28,723. J. de F. Maunder. Improvements in the treatment of ores. Dec. 4.

28,745. E. Smith and A. T. Smith. Improvements in the method and apparatus for annealing wire. Dec. 6.

28,896. J. Rudolphs and J. Landin. An improved method or process of extracting metals from pulverised or finely divided ores or compounds. Complete Specification. Dec. 7.

29,162. E. E. Atkins. Annealing metals. Dec. 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

26,297. J. Campbell. Method of and apparatus for treating refractory gold and silver, and other metal-bearing ores and materials. Dec. 1.

27,346. J. J. Shedlock. Extracting metals from their ores, and apparatus therefor. Nov. 24.

28,361. M. M. Marcus. Making metal alloys. Dec. 8.

28,880. C. de E. Llatas. Manufacture of steel. Dec. 15.

1897.

516. A. S. F. Robinson. Method and machinery or apparatus for extracting gold or other valuable metal from crushed ore or material containing it. Dec. 15.

880. A. Etard. Treatment of ores or other matters containing gold, silver, or copper, for the obtainment of the metal therefrom. Dec. 15.

1778. C. Wichmann. Extracting gold from ores. Dec. 15.

3303. F. W. Streathfield. Extracting metals from their ores, or in obtaining solutions of same. Dec. 1.

18,640. J. Landin. Wet process for extracting gold from gold ores or gold-ore waste. Dec. 15.

19,764. A. E. Thomas. Thomas's universal converter for cleansing molten iron from its impurities and converting the same into refined iron or malleable iron or steel as may be required to produce. Dec. 1.

24,121. W. P. Thompson.—From E. C. Ketchum. Process for treating mixed sulphide ores. Nov. 24.

# XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

## APPLICATIONS.

26,656. P. F. Ribbe. Improvements in and relating to electric accumulator plates. Complete Specification. Nov. 15.

26,680. A. Tribelhorn. Improvements in electric accumulators or storage batteries. Nov. 15.

26,880. G. W. B. Crees, W. L. Durban, and J. Gore. Improvements in and relating to electrical furnaces specially applicable for the production of calcium carbide. Nov. 17.

26,881. G. W. B. Crees, W. L. Durban, and J. Gore. Improvements in and relating to electrical furnaces specially applicable for the production of calcium carbide. Nov. 17.

26,919. O. C. Strecker and H. H. Strecker. Improvements in or relating to the application of electrodes in electrolytic processes. Complete Specification. Nov. 17.

26,921. O. C. Strecker and H. H. Strecker. Improved process for preparing insoluble or hardly soluble salts from metallic anodes by electrolysis of aqueous solutions containing two salts. Complete Specification. Nov. 17.

26,923. O. C. Strecker and H. H. Strecker. Improvements in or relating to the production of protoxides and oxides or of hydro-protoxides and hydroxides from metallic anodes by electrolysis of alkaline salt solutions. Complete Specification. Nov. 17.

27,129. A. L. C. Nodon, L. A. Bretonneau, and P. d'Alton Shée. A new or improved electrolytic method of and apparatus for saponification. Complete Specification. Nov. 19.

27,165. J. W. Townsend. Improvements in electrical storage batteries or accumulators. Nov. 19.

27,508. O. March. Improvements in and connected with the extraction of gold by electrolysis. Nov. 23.

27,551. J. W. Swan and A. C. Hyde. Improvements in means to be employed in the electrolysis of salts. Nov. 23.

27,683. W. H. Lane. Improvements in and connected with electrical storage batteries. Nov. 25.

27,706. J. E. Hartley and H. E. Hartley. Improvements in barrelling electro-metallic depositing apparatus. Nov. 25.

27,707. J. E. Hartley and H. E. Hartley. Improvements in rotative electro-metallic depositing apparatus. Nov. 25.

27,712. A. Hirsch. Improvements in electrodes for use in connection with apparatus for welding and soldering by means of electricity. Nov. 25.

27,940. M. Orban. Improvements in electric batteries. Nov. 27.

27,973. C. Clark. Improvements in charging secondary batteries or accumulators. Nov. 27.

27,982. W. Rowbotham. Improvements in primary batteries. Nov. 27.

28,212. H. Riecken. Improvements in the electrolytical treatment of ores and slimes for the recovery of precious metals therefrom, and apparatus therefor. Nov. 30.

28,242. P. J. R. Dujardin. Improvements in or relating to negative plates for secondary batteries. Nov. 30.

28,460. C. Payen. An improved electrical accumulator. Dec. 2. Date applied for, May 1, 1897, being date of application in Belgium.

28,795. H. J. Brown, O. R. H. Schmidt, and A. Macenzie. See Class XIII.

29,011. J. Bastick and W. A. Thornton. Improvements in or relating to electric furnaces for the production of calcium carbide and other substances. Dec. 8.

29,048. F. E. Elmore and A. S. Elmore.—From J. O. S. Elmore, India. Improvements in effecting electrolytic deposit of iron. Dec. 8.

29,180. P. Brandt. An improved electrical accumulator. Complete Specification. Dec. 9.

29,270. H. H. Lake.—From C. Francke, Germany. Improvements in plates or electrodes for electrical accumulators. Complete Specification. Dec. 10.

## COMPLETE SPECIFICATIONS ACCEPTED.

1897.

490. W. Wright. Electric deposition of metal on pipes, tubes, and other articles. Nov. 24.

615. E. Bohm. Means for electrically obtaining ore, and employing the same for curative and other purposes. Dec. 15.

1201. H. W. Hancock and A. H. Dykes. Method of preparing positive plates for secondary batteries. Dec. 8.

1627. A. E. Cook. Apparatus for the electro-deposition of metals. Dec. 8.

2709. W. E. Heys.—From E. Daumoulin. Improvements in the electro-deposition of copper and other metals. Dec. 8.

3346. C. Payen. Secondary batteries. Dec. 1.

14,708. G. H. Nash. Apparatus for coating metal articles by electro-deposition. Dec. 15.

19,648. R. Kennedy. Improvements in electrical storage batteries and plates therefor. Nov. 24.

19,846. L. Guelzow. Manufacture of plates for electric accumulators. Nov. 24.

21,704. S. W. Hart. Secondary electric batteries or accumulators. Nov. 24.

21,705. S. W. Hart. Secondary electric batteries or accumulators. Nov. 24.

22,203. A. J. Boulton.—From F. H. Soden, United States. Apparatus for electrically treating ore. Dec. 15.

24,150. H. S. Lloyd. Electrodes for storage batteries. Nov. 24.

25,386. H. K. Hess. Improvements in chemical electric generators. Dec. 15.

# XII.—FATS, OILS, AND SOAP.

## APPLICATIONS.

27,262. J. W. Owen. Improved detergents, and method of manufacturing the same. Nov. 20.

28,206. A. Euston. Improvements in the treatment of oleaginous seeds for the extraction of oil therefrom. Complete Specification. Nov. 30.

## COMPLETE SPECIFICATIONS ACCEPTED.

1896.

28,682. J. L. Garle and C. C. Frye. Process for the decolorisation of palm oil. Nov. 24.

1897.

751. J. T. Potts. Manufacture of soap. Nov. 24.

1305. J. C. Bryan and B. J. Sharpe. Washing solution. Dec. 8.

3700. J. David. Treatment of oleic acid. Dec. 1.

7256. H. H. Lake.—From F. W. Klever. A method of dissolving iodine in mineral oils. Dec. 1.

23,140. F. Arthur. A solution for washing and cleansing glass, and painted and varnished surfaces. Nov. 24.

23,197. J. Monterrubio. Improved system for manufacturing soaps by the direct employment of oleaginous seeds. Nov. 24.

# XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, ETC.

## APPLICATIONS.

26,800. C. J. Grist. Improvements in the manufacture of paints, anti-corrosive compositions, and compositions for like uses. Nov. 16.

26,867. J. S. Macarthur. Improved anti-fouling composition. Nov. 17.

28,481. H. Loeser. Improved manufacture of water-proof and weather-proof paint. Dec. 2.

28,795. H. J. Brown, O. R. H. Schmidt, and A. Mackenzie. A new or improved compound or material for electrical insulating purposes. Dec. 6.

29,092. M. Ziegler. Improvements in the treatment of decayed or putrid india-rubber. Dec. 9.

29,291. J. Kerner. The manufacture and production of an opaque pigment or body colour. Dec. 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1897.

3576. J. C. Mewburn.—From J. C. Taylor. Manufacture of anti fouling compositions or paints. Dec. 15.

9447. J. W. Blake and S. J. Blake. Compositions or paints for preserving structures. Nov. 24.

11,168. E. Garnier and S. J. Prescott. Improvements in india-rubber compounds and in gutta percha compounds. Dec. 15.

19,179. H. C. Woltereck. Manufacturing white-lead by electrolysis. Dec. 15.

21,718. R. Strobenz and J. Fried. Manufacturing black pigments from carbonaceous material. Dec. 8.

23,957. F. J. Bergmann. Production of graphite. Dec. 1.

24,504. A. Stoop. Improved process for the manufacture of paints and pigments. Dec. 15.

26,107. H. Markus and G. B. Behrens, of the firm of D. Lee and Co. Manufacture of india-rubber and gutta-percha. Dec. 15.

#### XIV.—TANNING, LEATHER, GLUE, AND SIZE.

##### APPLICATIONS.

26,677. W. F. Reid and E. J. V. Earle. Improvements in the manufacture of enamelled leather. Nov. 15.

26,760. H. Holmes. Improvements in the process of depilating hides or skins. Complete Specification. Nov. 16.

29,292. W. E. Heys.—From E. Dumoulin, France. Improvements in the method of and means for rendering animal, membranous, gelatinous, albuminous, fibrinous, and analogous substances, and articles composed of or containing such substances, insoluble. Dec. 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

28,067. E. A. Muskett and J. B. Seammell. Treatment of raw hides. Dec. 8.

1897.

1587. T. D. Bowman and J. Bowden. Manufacture of imitation leather. Dec. 8.

3180. S. Millar and C. E. Millar. Treating hides and skins. Dec. 8.

24,080. A. J. Boulton. From G. Brigalant, France. Treatment of leather waste, and apparatus employed therein. Dec. 1.

#### XVI.—SUGARS, STARCHES, GUMS, Etc.

##### APPLICATIONS.

26,985. J. Peeters. Process for the production of new vegetable extracts and new vegetable peptones of commercial utility by the transformation of all kinds of yeasts and these new products of commercial utility themselves. Complete Specification. Nov. 18.

27,050. A. Classen. Manufacture of soluble modifications of albuminous substances, and processes therefor. Nov. 18.

27,161. A. Classen. See Class XX.

27,534. W. P. Thompson.—From L. Bussy, H. Philippe, and P. Bussy, France. An improved impermeable water-resisting paste-gum or coating. Nov. 23.

28,589. J. J. Huguette. Improved process for the purification of saccharine juices, and apparatus therefor. Dec. 3.

29,292. W. E. Heys.—From E. Dumoulin, France. See Class XIV.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1897.

34. E. L. Newsome. Appliance for supplying glucose, syrup, or other material to preserving pans when boiling. Nov. 24.

1338. A. Verley. Manufacture of sugar. Nov. 24.

#### XVII.—BREWING, WINES, SPIRITS, Etc.

##### APPLICATIONS.

26,985. J. Peeters. See Class XVI.

27,376. W. Jago. An improvement in the manufacture and treatment of malt preparations. Nov. 22.

27,858. E. B. Ludlow. An improved appliance for aerating, rousing, and mixing fermenting and other liquids, or for lifting the same. Nov. 26.

28,579. C. Schmitz. An improved process and apparatus for producing beer-wort from malt flour. Complete Specification. Dec. 3.

29,089. G. F. Zimmer. Improvements in and connected with gelatinising and drying apparatus used in the manufacture of flaked maize malt and similar substances. Dec. 9.

29,157. H. M. Kettelwell. An improved method and apparatus for the prevention and extinction of fires in breweries, distilleries, and other like premises. Dec. 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

26,655. C. Zimmer. Process for brewing. Dec. 1.

1897.

2287. E. E. M. Payne, T. O. Kent, and E. E. Pullman. Compositions or mixtures to be used for the preservation of malt liquors, such as ale, beer, stout, porter, and other like saccharine liquids, and methods of using and applying such compositions or mixtures. Dec. 8.

13,722. J. Goodfellow. Manufacture of nutritious products from yeast. Dec. 1.

16,232. H. Hempel. Process for producing a carbonaceous agent for enriching spirit. Nov. 24.

21,878. E. Zdarek. Manufacture of ethyl alcohol. Nov. 24.

#### XVIII.—FOODS, SANITATION, Etc., AND DISINFECTANTS.

##### APPLICATIONS.

##### A.—Foods.

26,574. L. Checkemian. Improved food preparations, mageritaze, mazoon, or tog hourt, a most delicious, nourishing and appetising food. Nov. 15.

26,628. A. Schmidt. Process for the production of food for cattle. Complete Specification. Nov. 15.

26,658. F. H. M. Röver. Improvements in or relating to the preservation of eggs. Complete Specification. Nov. 15.

26,754. W. G. Day. Improvements in methods of preserving perishable substances. Complete Specification. Nov. 16.

27,439. P. Ghinozzi. New process for preserving food and all kinds of organic substances. Nov. 23.

27,617. W. Lanwer. New or improved process for preserving meat and other alimentary substances. Nov. 24.

28,359. M. Delavigne, C. Helmerich, and A. Kluglein. An improved process and apparatus for the preservation of eggs. Complete Specification. Dec. 1.

28,379. H. H. Lake.—From A. Moyet, France. Improvements in apparatus for sterilising meat in the raw state. Dec. 1.

29,189. A. Bernstein. The manufacture of a substitute for eggs. Dec. 9.

#### B.—Sanitation.

26,625. H. G. Downton and W. H. Nicholls. Improvements in process and apparatus for the destruction of night soil and noxious matters. Complete Specification. Nov. 15.

26,821. W. A. Clark. Improvements in the method of and apparatus for the treatment of sewage. Nov. 16.

26,959. G. Hincheliffe, H. T. Hirst, and J. R. Hincheliffe. An improved treatment for precipitating, clarifying, and purifying sewage and waste or foul water. Nov. 18.

27,004. J. G. Dornig, F. H. Bachlitz, and T. Zeunert. Improved process and means for the sanitary disposal of human excrement, and the production therefrom of gas and by-products serving for manure and other purposes. Complete Specification. Nov. 18.

27,026. H. McPhail. Improvements in heating, softening, and purifying water, and apparatus therefor. Nov. 18.

27,306. H. Morris. Improvements in and connected with the treatment of sewage and other waste liquids. Nov. 22.

27,349. D. Cameron, F. J. Commin, and A. J. Martin. Improvements in apparatus for the treatment of sewage or other liquids. Nov. 22.

28,164. G. Krell and M. Elb. An improved disinfecting process by means of methylaldehyde or polymeric methylaldehydes, and method of employing same. Nov. 30.

29,090. A. B. Ogden. New process or system of sewage and foul water purification by electrical action. Dec. 9.

29,160. J. Hardwick. Improvements in or relating to the treatment of sewage. Dec. 9.

#### COMPLETE SPECIFICATIONS ACCEPTED.

##### A.—Foods.

1897.

4447. J. Imray.—From La Soc. Anonyme des Matières Colorantes et Produits Chimiques de St. Denis and D. A. Rosenstiel. Process for preserving alimentary substances. Nov. 24.

##### B.—Sanitation.

1896.

27,513. F. P. Candy. Purification of sewage and polluted waters. Dec. 15.

#### XIX.—PAPER, PASTEBOARD, Etc.

##### APPLICATIONS.

27,477. A. S. Caldwell. Improvements in and relating to the production of water marks in paper. Nov. 23.

28,187. A. S. Caldwell. Improvements in and relating to the production of water marks in paper. Nov. 30.

28,982. F. Langley, J. Whittingham, and J. Harris. Improvements in the process of and apparatus for sizing paper. Dec. 8.

29,032. A. J. Boulton.—From R. Scholich and O. Kunze, Germany. Improved manufacture of sanitary paper of material for toilet purposes. Dec. 8.

#### COMPLETE SPECIFICATION ACCEPTED.

1897.

21,560. E. Cox, F. Kornacher, and M. Bruum. Improved writing paper, and ink therefor. Dec. 15.

#### XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

##### APPLICATIONS.

27,032. H. J. H. Fenton and E. S. St. Barbe Sladen. An improved process for the production of dehydroxy-tartaric acid. Nov. 18.

27,161. A. Classen. Manufacture of compounds of starch-like bodies and gums with acetaldehyde and paraldehyde, and processes therefor. Nov. 19.

27,493. A. J. Boulton.—From A. Revollier, Belgium. Improved manufacture of camphor sulphonic acids. Nov. 22.

28,167. O. Imray.—From La Société Fabriques de Produits Chimiques de Thann et de Mulhouse, Germany. Improvements in the manufacture of artificial musk. Dec. 2.

29,061. S. Pitt.—From The Pharmaceutische Institut Ludwig W. Gans, Germany. The production of the operative substance from the thyroid glands and other organs in an unaltered uncoagulable state. Dec. 8.

29,308. A. Goldberg, W. Siepermann, and H. Flemming. A process for the preparation of guanidine salts. Dec. 10.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

26,078. W. B. Bishop. Treatment of piperazine. Nov. 24.

1897.

2472. J. Y. Johnson.—From C. F. Boehringer and Soehne. Preparation of hydroxycaffeine by the direct methylation of uric acid or of certain mono- and dimethyl-derivatives thereof also obtainable in the process. Dec. 8.

2556. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of nitroal phylpyruvic acids. Dec. 8.

3957. J. Y. Johnson.—From C. F. Boehringer and Soehne. Manufacture or preparation of dichloroxy purine. Dec. 15.

25,945. W. P. Thompson.—From J. Brissonnet, France. Improved cresote compound. Dec. 15.

#### XXI.—PHOTOGRAPHY.

##### APPLICATIONS.

27,033. J. C. Fell.—From M. W. McDonald, United States. Matt surface photographic paper, and process of making same. Complete Specification. Nov. 18.

28,596. J. Hauff. Photographic developers. Complete Specification. Dec. 3.

28,920. J. W. Bennetto. Improvements in the production of coloured photographs, and apparatus for that purpose. Dec. 7.

29,093. K. Marten. An improved method of producing pictures upon glass by lithography in one or more colours. Dec. 9.

#### XXII.—EXPLOSIVES, MATCHES, Etc.

##### APPLICATIONS.

26,896. C. A. McEvoy. Improvements in time and percussion fuses. Nov. 17.

26,962. J. C. Hamilton. Improvements in the manufacture of blasting compounds. Nov. 18.

27,100. T. Lochtie. Safety waterproof couplings for detonators and fuses. Nov. 19.

27,174. H. de Stedingk. An improvement connected with explosive cartridge fuses. Nov. 19.

27,234. J. Fraser. Improvements in mining and like fuses, and means for igniting same. Nov. 20.

27,520. J. Craveri. Improvements relating to the manufacture of safety matches and rubbing surfaces therefor. Complete Specification. Nov. 23.

27,912. J. C. Hamilton. Improvements in the detonation of certain blasting compounds. Nov. 27.

28,152. J. C. Hamilton. Improvements in or relating to blasting compounds. Nov. 30.

28,476. R. T. Maguire and D. P. Maguire. Improvements in or relating to lucifer matches. Dec. 2.

28,807. D. W. Nightingale. Improvements in explosives. Dec. 6.

29,005. L. Davies. Improvements in explosives. Dec. 8.

29,064. F. A. Debize and L. F. Chasseigne. Improvements in machinery for the continuous manufacture of wooden matches. Complete Specification. Dec. 8.

29,202. J. Joscht. Improvements in the manufacturing of matches. Dec. 9.

29,204. J. Bown. Improvements in fog signals. Dec. 9.

29,389. F. L. Thomas.—From La Société des Poudres et Dynamites, France. An improvement in explosives. Dec. 11.

#### COMPLETE SPECIFICATIONS ACCEPTED.

1896.

27,197. A. Nobel. Manufacture of explosive compounds. Dec. 8.

28,890. G. Kynoch and Co., Ltd., and A. T. Cocking. Manufacture of nitroglycerin. Dec. 8.

1897.

651. W. Greaves and E. M. Hann. Improvements in explosives. Dec. 15.

2557. M. Biedefeldt. Manufacture of explosives. Dec. 8.

3135. H. R. von Dalmen. Improvements in blasting compositions. Dec. 8.

25,204. J. C. Chapman.—From C. W. Volney, United States. Manufacture of gunpowder. Dec. 8.

25,413. J. C. Chapman.—From C. W. Volney, United States. An improved gunpowder. Dec. 8.

#### XXIII.—ANALYTICAL CHEMISTRY.

##### APPLICATION.

27,373. C. E. Müller and R. F. Hurran. *See* Class I.

#### PATENTS UNCLASSIFIABLE.

##### APPLICATIONS.

27,121. W. Leuscher. A process for the manufacture of burnt filtering mass. Complete Specification. Nov. 19.

27,661. M. Weishaus. Process for regenerating used whalebone and for dressing fin-whalebone without rendering the same brittle. Complete Specification. Nov. 24.

27,877. J. Rodgers. Improvements in the petrification or incrustation of porous or other substances. Nov. 26.

29,059. A. J. de Hailes. Improvements in preparations for rendering inflammable materials resistant to fire. Dec. 8.

29,387. L. C. Reese. Improvements in the extraction from liquids of matters therein contained. Dec. 11.
